Re: ***Petition Of Tennessee American Water Company To Change And Increase Certain Rates And Charges So As To Permit It To Earn A Fair And Adequate Rate Of Return On Its Property Used And Useful In Furnishing Water Service To Its Customers***
Docket No. 08-00039

Dear Chairman Roberson:

Enclosed please find an original and seven (7) copies of Tennessee American Water Company's Responses to the Remainder of the Requests Contained in the First Discovery Request of the Consumer Advocate and Protection Division to Tennessee American Water Company.

In addition, two compact disks have been provided. The first disk contains all of the Company's responses in Word or Excel to data requests. The second disk contains all such responses in pdf format.

Please stamp three (3) copies of these Discovery Responses as "filed," and return them to me by way of our courier.

Should you have any questions concerning any of the enclosed, please do not hesitate to contact me.

Sincerely,

Ross Booher (by kkw)

Ross I. Booher

IN RE:

PETITION OF TENNESSEE AMERICAN WATER COMPANY TO CHANGE AND INCREASE CERTAIN RATES AND CHARGES SO AS PERMIT IT TO EARN A FAIR AND ADEQUATE RATE OF RETURN ON ITS PROPERTY USED AND USEFUL IN FURNISHING WATER SERVICE TO ITS CUSTOMERS	)	**Docket No. 08-00039**

TENNESSEE AMERICAN WATER COMPANY'S RESPONSES TO THE REMAINDER OF THE REQUESTS CONTAINED IN THE FIRST DISCOVERY REQUEST OF THE CONSUMER ADVOCATE AND PROTECTION DIVISION TO TENNESSEE AMERICAN WATER COMPANY

The Tennessee American Water Company ("TAWC") hereby responds as follows to the remainder of the requests contained of the First Discovery Request of the Consumer Advocate and Protection Division ("CAPD") to the TAWC:

GENERAL OBJECTIONS

(1) TAWC objects to all requests that seek information protected by the attorney-client privilege, the work product doctrine and/or any other applicable privilege or restriction on disclosure.

(2) TAWC objects to the definitions and instructions accompanying requests to the extent definitions and instructions contradict, are inconsistent with, or impose any obligations beyond those required by applicable provisions of the Tennessee Rules of Civil Procedure or the rules, regulations or orders of the Tennessee Regulatory Authority.

(3) To the extent contained in the Requests, TAWC objects to the definitions of the words "document," "you," "person," "persons," "affiliate," "affiliated," "identify," "identifying,"

"identification," and "referring or relating to," that accompany the data requests because such definitions are overbroad and unduly burdensome.

(4) The specific responses set forth below are based upon information now available to TAWC, and TAWC reserves the right at any time to revise, correct, add to or clarify the objections or responses and supplement the information and/or documents produced.

(5) TAWC is providing its responses herein without wavier of, or prejudice to, its right at any later time to raise objections to: (a) the competence, relevance, materiality, privilege, or admissibility of the response, or the subject matter thereof; and (b) the use of any response, or subject matter thereof, in any subsequent proceedings.

(6) TAWC objects to each request to the extent that it is unreasonably cumulative or duplicative, or seeks information obtainable from some other source that is more convenient, less burdensome or less expensive.

(7) TAWC objects to each request to the extent it is premature such that it seeks information concerning matters about which discovery is ongoing and/or seeks information to be provided by expert witnesses.

(8) TAWC objects to each request to the extent it seeks information outside TAWC's custody or control.

(9) TAWC objects to requests that call upon TAWC to create, categorize, manipulate, customize or otherwise organize data regarding time periods outside of TAWC's historical test year. TAWC objects to all such requests because they are unduly burdensome, seek to have TAWC create work product and seek information that is not relevant to this rate case.

(10) TAWC's specific objections to each request are in addition to the General Objections set forth in this section. These General Objections form a part of each discovery

response, and they are set forth here to avoid the duplication and repetition of restating them for each discovery response. The absence of a reference to a General Objection in response to a particular request does not constitute a waiver of any General Objection with respect to that discovery request. All responses are made subject to and without waiver of TAWC's general and specific objections.

Respectfully Submitted,

R. Dale Grimes (#6223)

TENNESSEE AMERICAN WATER COMPANY
DOCKET NO. 08-00039
FIRST DISCOVERY REQUEST OF THE
CONSUMER ADVOCATE AND PROTECTION DIVISION

Responsible Witness: John J. Spanos

PART II: DEPRECIATION & WEATHER NORMALIZATION

Question:

53. Were any retirements, classified as sales or reimbursements, excluded from the life studies? If yes, were the retirements and related gross salvage and cost of removal also excluded from the net salvage studies?

Response:

There were no retirements classified as sales or reimbursements excluded to the extent to which salvage receipts represent recovery of original cost.

TENNESSEE AMERICAN WATER COMPANY
DOCKET NO. 08-00039
FIRST DISCOVERY REQUEST OF THE
CONSUMER ADVOCATE AND PROTECTION DIVISION

Responsible Witness: Michael Miller

PART II: DEPRECIATION & WEATHER NORMALIZATION

Question:

54. Please identify and explain the Company's expectations with respect to future removal requirements and markets for retired equipment and materials. Please provide the basis for these expectations.

Response:

TAWC has had a long history of installing and retiring plant in service. The historical experience of the Company in this area provides a sound basis for the determination of service life estimates for Company's many property groups. In addition to the Company's considerable experience in property retirements, the Company has a long history of the applicable costs associated with those retirements of property related to cost of removal and salvage. This historical information provides a solid benchmark from which to assess the historical experience and to extrapolate such costs for the purpose of estimating future end of life costs and any potential salvage amounts. Due to the long service lives of most of the Company's property; most of it being underground, and most of the property being specialized for a water utility, there is little expectation or likelihood that the property will have material value to another user. History tells us that we can expect only immaterial levels of salvage on utility plant other than on vehicles.

Conversely, history tells us that the cost of to remove the vast majority of the utility plant of the Company is significant in comparison to the original cost of

those assets due to the inflation of removal costs over the extremely long service lives of most water utility plant in service. It requires both Company labor and contractors to disconnect the property from service and/or physically remove and dispose of the assets. The cost to retire facilities far exceeds the salvage value and the original cost of the assets for most of the Company's utility plant groups.

The Company expects the future removal costs and salvage to hold to the historical information and trends utilized by Mr. Spanos in arriving at his service lives and net negative salvage components of his depreciation rate recommendations.

CONSUMER ADVOCATE AND PROTECTION DIVISION

Responsible Witness: John J. Spanos

PART II: DEPRECIATION & WEATHER NORMALIZATION

Question:

56. Provide the calculation of the annual amount of future net salvage incorporated into the Company's proposed depreciation rates by account as of November 30, 2007. If the amount is reduced by the total amount of legal ARO's included in year-end accumulated depreciation, show that calculation.

Response:

The attached spreadsheet sets forth the annual amount of future net salvage incorporated in the Company's proposed depreciation rates by account as of November 30, 2007.

These accounts are not reduced by legal ARO's.

Responsible Witness: Michael Miller

PART II: DEPRECIATION & WEATHER NORMALIZATION

Question:

57. Please provide all manuals, guidelines, memoranda or other documentation that deal with the Company's policies with regard to the physical removal of plant in the following accounts:

Response:

Please see Confidential Document submitted pursuant to Protective Order dated May 23, 2008.

TENNESSEE AMERICAN WATER COMPANY
DOCKET NO. 08-00039
FIRST DISCOVERY REQUEST OF THE
CONSUMER ADVOCATE AND PROTECTION DIVISION

Responsible Witness: John S. Watson/Michael Miller

PART II: DEPRECIATION & WEATHER NORMALIZATION

Question:

58. Please provide a summary of Main and Service Replacement projects during 2006 and 2007. Separately identify all major costs, including the removal of the existing Main and/or Service.

Response:

The Company objects to this request on the grounds that it is vague and ambiguous, over broad, and unduly burdensome. Furthermore, the information is not readily available to the Company in the requested format. This request involves hundreds, if not thousands, of individual work orders. In order to produce and compile the requested information, the Company would have to research each of those work orders, which would take countless hours of effort. Due to the magnitude of individual work orders covering this work, the Company will make the responsive records available for the CAPD to review at its office at a mutually agreeable time.

Subject to and without waiving its objections, the Company provides the following response.

Attached is a listing of the water mains that were installed to replace/restore existing mains during 2006 and 2007. The examples of categories of items that contribute to the total cost are materials such as pipe, valves and contracted work, as well as inspection services, paving, and street cut permits.

FIRST DISCOVERY REQUEST OF THE
CONSUMER ADVOCATE AND PROTECTION DIVISION

Responsible Witness: Michael Miller

PART II: QUESTIONS & REQUESTS REGARDING DEPRECIATION & WEATHER NORMALIZATION

Question:

59. With Respect to for each of the mass property accounts for which there is net salvage, please provide for the each of the last 10 years:
    a. The number of plant units retired each year, and
    b. The total number of plant units in the Company's system.

Response:

a. The Company objects to this question on the grounds that the request is overbroad, not readily available in the format requested, and would be unduly burdensome to produce the data prior to 2001 due to the extensive effort and cost required to develop such data. Subject to and without waiving its objections, please see the Table below. The data provided represents units of each Mass Property Account retired in the last 7 years. The data includes multiple retirement units in each Mass Property account, for example, Mains include not only length of pipe retired but also Qty of valves, Qty of valve-boxes, etc. The same is true for each of the Mass Property Accounts.

			Units Retired		
Account	331	333	334	334	335
Year	Mains(FT)	Services(EA)	Meters(EA)	Meter Install(EA)	Hydrants(EA)
2001	39,781	132	3,961	322	134
2002	19,768	122	3,571	277	32
2003	36,310	181	1,850	445	84
2004	19,900	112	1,324	257	101
2005	18,115	59	4,676	170	65
2006	49,882	43	6,146	55	110
2007	22,174	0	17	0	36
	205,930	649	21,545	1,526	562

b. The Company objects to this request as overbroad and unduly burdensome. The requested data is not readily available in the format requested and to produce the data prior to 2001 would require extensive effort and cost to develop. Subject to and without waiving its objections, the Company responds that the total units in-service for each Mass account is presented in the table below. The data is for only the major property unit in each account. Mains, for example, shows total footage of main and does not count valves as an item.

Account	Mains(FT) 331	Services(EA) 333	Meters(EA) 334	Meter Install(EA) 334	Hydrants(EA) 335
Total Quantity In-Service	6,744,148	76,982	75,792	75,792	4,989

PART II: DEPRECIATION & WEATHER NORMALIZATION

Question:

63. Does TAWC consider that it is bound by SEC regulations to record accruals for future costs of removal as regulatory liabilities?
    a. If so, please provide a record of those accruals in as much account detail as is available along with the workpapers used to develop those accruals.
    b. If not, please explain why not.
    c. State whether the Company proposes to separate retirement cost accounting from depreciation accounting, with separate rates and reserves. If the Company does not propose such separation, please state fully the reasons for not doing so.

Response:

This question appears to be duplicative to Part II, Question 35 if one assumes the SEC requires financial statement presentation to comply with U.S. GAAP. Please see the response to Part II, Question 35.

a. Please see the response to Part II, Question 34.
b. Not Applicable.
c. No. This practice is not followed by most regulatory commissions (including the TRA) across the country, it is not consistent with the remaining life depreciation methods utilized to establish the Company's current depreciation rates and the depreciation rates of most utility companies, and is not consistent with the remaining life depreciation

methodologies recommended by the Company's expert witness, John Spanos, or the depreciation study prepared for TAWC and previously produced in this case.

PART II: DEPRECIATION & WEATHER NORMALIZATION

Question:

64. State whether PSE has forecast any non-legal removal costs that it does not regard as regulatory liabilities. Please describe these costs in detail, state fully the reason(s) for your belief that such forecast costs are not regulatory liabilities, and identify the forecast amounts of such removal costs in as much detail as is available. Provide the supporting documentation for each forecast amount.

Response:

The Company objects to this question on the grounds that it clearly is not intended for TAWC. Notwithstanding the objection, please see the response to Part II, Question 35 (b) for the Company's position on legal versus non-legal removal costs per the definitions included in SFAS 143. Also see the response to Part II, Question 34 which provides the Company's calculations and workpapers regarding the reclassifications of NNS required by SFAS 143.

Responsible Witness: Michael J. Vilbert

PART III: QUESTIONS & REQUESTS REGARDING COST OF CAPITAL & MISCELLANEOUS

Question:

1. Regarding Dr. Vilbert's testimony filed in this docket, provide copies of the following items referenced in Dr. Vilbert's testimony:

   a Electronic copies of all documents, testimony and comments listed by Dr. Vilbert at page A-7 of 7 in Appendix A.

   b. Provide legible source pages for all references to Value Line Standard Edition, Value Line Plus Edition, Bloomberg, Blue Chip Economic Indicators, and Mergent Bond Record.

   c. Provide legible copies pages of workpapers given by Tennessee-American or its parent, American Water Works to Dr. Vilbert, which Dr. Vilbert relied on to prepare his testimony.

Response:

a. Due to the size of these documents, please refer to the enclosed CD. The electronic documents are named TN-CAPD-01-PART III-Q001a-ATTACHMENT 1.pdf through TN-CAPD-01-PART III-Q001a-ATTACHMENT 7.pdf, with the exception of the rebuttal testimony before the Public Utilities Commission of the State of South Dakota, Docket No. NG-07-013, on behalf of NorthWestern Corporation, on the Cost of Capital for NorthWestern Energy Company's natural gas operations in South Dakota, November 2007. This rate case was settled just before the stage

at which rebuttal testimony was filed. The rebuttal testimony was therefore incorrectly included in Dr. Vilbert's resume. An errata to Dr. Vilbert's Appendix A is attached to this response to reflect the correction of this error.

b. The requested documents are located on the enclosed CD named TN-CAPD-01-PART III-Q001b-ATTACHMENT.pdf, with the exception of Bloomberg source pages. Historical data regarding stock prices, dividend payments, interest rates, yields on public utility bonds, and balance sheet and income statement figures that were used in the calculation of the estimated ROE are included in the Tables and Workpapers submitted with Dr. Vilbert's testimony. This information was extracted from Bloomberg directly into the Excel spreadsheets, and therefore no source pages can be provided. The remaining Bloomberg information concerns bond ratings and M&A activity of sample companies. This information was reviewed on a computer screen using a licensed Bloomberg terminal. Licensing terms prevent Dr. Vilbert from providing printouts of any Bloomberg terminal information.

c. Dr. Vilbert relied on the regulatory capital structure information provided by Tennessee American. The worksheet containing that information is located in the enclosed CD named TN-CAPD-01-PART III-Q001c-ATTACHMENT.pdf.

I. INTRODUCTION AND SUMMARY

Q1. Please state your name and address for the record.

A1. My name is Michael J. Vilbert. My business address is The Brattle Group, 44 Brattle Street, Cambridge, MA 02138, USA.

Q2. Please describe your job and your educational experience.

A2. I am a Principal of The Brattle Group, ("Brattle"), an economic, environmental and management consulting firm with offices in Cambridge, Washington, London, San Francisco and Brussels. My work concentrates on financial and regulatory economics. I hold a B.S. from the U.S. Air Force Academy and a Ph.D. in finance from the Wharton School of Business at the University of Pennsylvania.

Q3. What is the purpose of your testimony in this proceeding?

A3. I have been asked by Wisconsin Electric Power Company ("Wisconsin Electric)" and Wisconsin Gas LLC ("Wisconsin Gas") (collectively the "Applicants") to estimate the costs of equity that the Public Service Commission of Wisconsin ("PSCW" or the "Commission") should allow them the opportunity to earn on the equity financed portions of their operations. Wisconsin Electric is an integrated electric utility with limited natural gas distribution activities, and Wisconsin Gas provides retail gas distribution service in Wisconsin (i.e., a natural gas local distribution company or "LDC").

To accomplish this task, I estimate the overall cost of capital for two samples, a sample of regulated electric companies and a sample of regulated natural gas LDCs using the discounted cash flow ("DCF") and risk positioning models. I then evaluate the relative business and financial risk of Wisconsin Electric to the electric sample and that of Wisconsin Gas to the gas LDC sample. These comparisons are important in determining my recommended cost of equity for a regulatory capital structure with 55.4 percent equity (Wisconsin Electric) or 52.2 percent equity (Wisconsin Gas), which is the percentage of equity in the Applicants' proposed capital structures in this proceeding.

Q4. Please summarize the parts of your background and experience that are particularly relevant to your testimony on these matters.

A4. Brattle's specialties include financial economics, regulatory economics, and the gas and electric industries. I have worked in the areas of cost of capital, investment risk and related matters for many industries, regulated and unregulated alike, in many forums. I have testified or filed cost of capital testimony before the Federal Energy Regulatory Commission, the Arizona Corporation Commission, the Pennsylvania Public Utility Commission, the Public Service Commission of West Virginia, the Tennessee Regulatory Authority, the Canadian National Energy Board, Alberta Energy and Utilities Board, the Ontario Energy Board, and the Labrador & Newfoundland Board of Commissioners of Public Utilities. I have not previously testified before this Commission. Appendix A contains more information on my professional qualifications.

Q5. Please summarize how you approached this task.

A5. With respect to Wisconsin Electric, I review the evidence from a sample of regulated electric utilities which were selected to have comparable business risk to Wisconsin Electric.[1] Similarly, I select a sample of regulated natural gas LDCs with comparable business risk to Wisconsin Gas. My analyses consider cost of capital evidence from the risk positioning and discounted cash flow models for both samples, but I rely primarily on the results from the risk positioning model because I do not believe that the DCF method is completely reliable at this time for these industries.

Specifically, I estimate the cost of equity for the companies in both samples using both cost-of-equity estimation methods. I combine each cost-of-equity estimate with the sample company's market costs of debt and preferred stock to calculate each firm's overall cost of capital, i.e. its after-tax weighted-average cost of capital ("ATWACC"), using each company's market value capital structure as the weights. For each method of estimating the return on equity, I report the sample average ATWACC and the estimated cost of equity for each of the regulated companies as if the sample companies had a capital structure with same percentage of equity as filed by each of the Applicants. I thus

[1] Wisconsin Electric has about 10 percent of its regulated assets devoted to providing local distribution service for natural gas customers, but Wisconsin Electric is primarily an integrated electric utility.

present the cost of equity that is consistent with each sample's market information and the regulatory capital structures of Wisconsin Electric and Wisconsin Gas. (By "regulatory capital structure," I mean the capital structures that the Applicants utilize in their applications.[2])

This method automatically avoids problems that can arise when an analyst focuses separately on the individual components of the overall cost of capital (i.e., the cost of equity and the appropriate capital structure). The danger with that approach is that the estimated cost of equity from the sample may correspond to a very different level of financial risk than would exist at the regulated company's capital structure. The result could be an inconsistency between the allowed return on equity and the financial risk inherent in the regulatory capital structure.

Q6. Why do you believe that the DCF model is less reliable for these industries at this time than the risk positioning model?

A6. Results for the DCF model depend critically on the estimate of the dividend growth rate. A one percent error in the estimate of the growth rate results in a greater than one percent error in the cost of equity estimates. Several of the sample companies have only one or two analyst forecasts, and forecast growth rates are likely to have been affected by the uncertainty in the industry. For example, the move toward a restructured industry featuring greater competition among providers of generation services has stalled and the future structure of the electric industry remains in doubt. The governor in Virginia has signed into law a bill that would reverse the restructuring in that commonwealth,[3] and similar moves are occurring in Connecticut, Montana, and Maryland.[4] The legislature in Illinois has proposed extending through 2011 the rate cap on the cost of power that is less

[2] The capital structure that I use in the analyses that follow is based upon the long-term sources of capital, i.e., long-term debt, preferred equity and common equity. I do not use short-term debt because long-term assets are not generally financed with short-term debt. For Wisconsin Electric, I include capitalized leases but not imputed debt from purchased power agreements in debt because this is consistent with the measure of financial risk for the sample companies.

[3] See "Virginia's electric power play," *The Washington Times,* April 9, 2007.

[4] See "Expectations zapped: Power prices putting utilities in the hot seat," *Worcester Business Journal*, 16 April 2007.

than the current market price of power.[5] There have been a number of mergers and acquisitions with the gas LDC industry recently, and gas prices have increased dramatically and have been much more volatile lately. Although most of the companies in both of the samples have fuel cost adjustment clauses, the increased volatility of gas prices has increased the uncertainty of both industries' earnings going forward. These facts are not a description of industries that could be characterized as stable, with earnings and dividends likely to grow at a constant rate over the foreseeable future. However, this stability is precisely the condition necessary for the reliable implementation of the DCF model.

In addition, the DCF model results display a greater spread and are more variable and less reliable than those based upon the risk positioning model; however, I provide results using the DCF method, because it is a method that has been relied upon by commissions frequently in the past. In addition, results from the DCF model serve as a check on the results from the equity risk positioning approach.

Q7. You mentioned the importance of considering financial risk when evaluating the results of the models. Please explain how you adjust for financial risk.

A7. Both the DCF and the risk positioning models rely on market data to estimate the cost of equity for the sample companies. That cost of equity estimate captures both the business risk and the financial risk of the assets. Business risk is the risk that the company would have if it were financed entirely with equity. Financial risk is the additional risk carried by the equity holders when debt is used to finance some of the assets. The more debt that is used by a company, the riskier the company's equity becomes. As explained in more detail below, the procedures I use consider both the business risk and the financial risk of the sample companies in comparison to Wisconsin Electric and Wisconsin Gas in determining my recommended costs of equity.

[5] See "Excelon shares slip on Illinois rate freeze fears." Reuters, March 22, 2007 and "It's hard to get free of Illinois' electric power rate tar pit," *St. Louis Post Dispatch*, March 11, 2007.

Q8. What is your conclusion on the market-determined costs of capital for Wisconsin Electric and Wisconsin Gas based upon the results from the samples of regulated companies you selected?

A8. For a capital structure with 55 percent equity, the sample results indicate a range for the cost of equity estimate for Wisconsin Electric of 10½ to 11½ percent. I believe this is a conservative estimate for reasons I discuss below, but I feel more comfortable with estimates in the upper half of the range. For Wisconsin Gas, with a capital structure with 52 percent equity, I estimate the range for the cost of capital to be 11 percent to 12 percent. I understand that the Applicants are requesting that the Commission authorize a single 11.2 percent cost of equity for both companies (after a change in risk profile due to the sale of the Point Beach Nuclear Plant). Based on my analyses, I believe that request is reasonable and fully consistent with the evidence from the two samples.

Note that I specify a plus or minus ½ percent range for the return on equity and specify the point estimate to the nearest ¼ percent because I do not believe that it is possible to estimate the cost of equity more precisely than that.

Q9. How is your testimony organized?

A9. *Section II* formally defines the cost of capital and touches on the principles relating to the cost of capital and capital structure for a business. *Section III* presents the methods used to estimate the cost of capital for the benchmark samples and their associated numerical analyses, and explains the basis of my conclusions for the benchmark samples' returns on equity and overall costs of capital. *Section IV* presents the results of these methods applied to the benchmark sample groups, and presents the costs of equity implied by the results. My conclusions on the cost of equity for Wisconsin Electric and Wisconsin Gas are presented in *Section V*. *Appendix B* provides additional detail on the sample selection process and the calculation of the market value capital structures of the sample companies. *Appendices C and D* support *Sections III and IV* with additional details on the risk positioning model and DCF approach, respectively, including the details of the numerical analyses. *Appendix E* discusses the effect of debt on the cost of equity in more detail.

II. COST OF CAPITAL THEORY

A. THE COST OF CAPITAL AND RISK

Q10. Please formally define the "Cost of Capital."

A10. The cost of capital can be defined as *the expected rate of return in capital markets on alternative investments of equivalent risk*. In other words, it is the rate of return investors require based on the risk-return alternatives available in competitive capital markets. The cost of capital is a type of opportunity cost: it represents the rate of return that investors could expect to earn elsewhere without bearing more risk. "Expected" is used in the statistical sense: the mean of the distribution of possible outcomes. The terms "expect" and "expected" in this testimony, as in the definition of the cost of capital itself, refer to the probability-weighted average over all possible outcomes.

The definition of the cost of capital recognizes a tradeoff between risk and return that is known as the "security market risk-return line," or "security market line" for short. This line is depicted in Figure 1. The higher the risk, the higher is the cost of capital. A version of Figure 1 applies for all investments. However, for different types of securities, the location (i.e., the intercept and the slope) of the line may depend on corporate and personal tax rates.

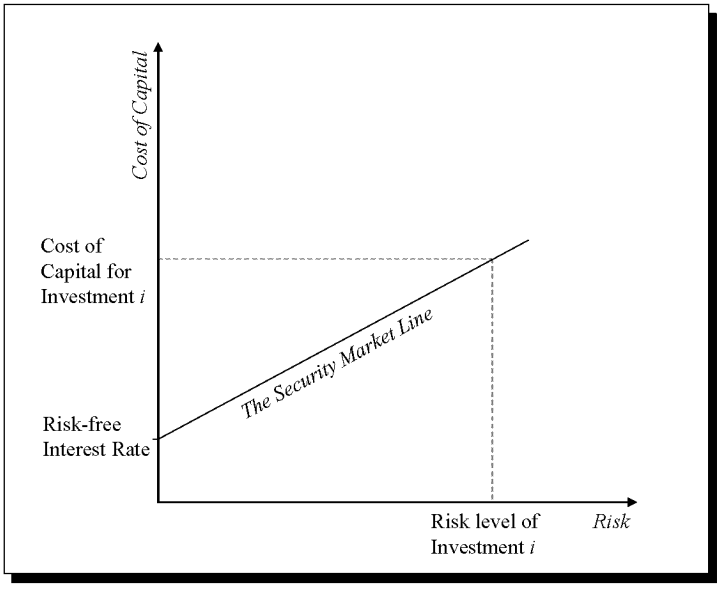

Figure 1: The Security Market Line

Q11. Why is the cost of capital relevant in rate regulation?

A11. It has become routine in U.S. rate regulation to accept the "cost of capital" as the right expected rate of return on utility investment.[6] That practice is normally viewed as consistent with the U.S. Supreme Court's opinions in *Bluefield Waterworks & Improvement Co. v. Public Service Commission*, 262 U.S. 678 (1923), and *Federal Power Commission v. Hope Natural Gas*, 320 U.S. 591 (1944).

From an economic perspective, rate levels that give investors a fair opportunity to earn the cost of capital are the lowest levels that compensate investors for the risks they bear. Over the long run, an expected return above the cost of capital makes customers overpay for service. Regulatory commissions normally try to prevent such outcomes, unless there are offsetting benefits (e.g., from incentive regulation that reduces future costs). At the same time, an expected return below the cost of capital does a disservice to investors and customers. In the long run, such a return denies the company the ability to attract capital, to maintain its financial integrity, and to expect a return commensurate with that of other enterprises attended by corresponding risks and uncertainties.

More important for customers, however, are the economic issues an inadequate return raises for them. In the short run, deviations of the expected rate of return on the rate base from the cost of capital create a "zero-sum game"-- investors gain if customers are overcharged, and customers gain if investors are shortchanged. In the long run, however, inadequate returns are likely to cost customers -- and society generally -- far more than is gained in the short run. Inadequate returns lead to inadequate investment, whether for maintenance or for new plant and equipment. The costs of an undercapitalized industry can be far greater than the short-run gains from shortfalls in the cost of capital. Moreover, in capital-intensive industries (such as the electric utility or the gas distribution industries), systems that take a long time to decay cannot be fixed overnight. Thus, it is in the customers' interest not only to make sure the return investors expect does not

[6] A formal link between to the cost of capital as defined by financial economics with the right expected rate of return for utilities is established by Stewart C. Myers, "Application of Finance Theory to Public Utility Rate Cases," *The Bell Journal of Economics and Management Science*, 3:58-97 (Spring 1972).

exceed the cost of capital, but also to make sure that it does not fall short of the cost of capital, either.

Of course, the cost of capital cannot be estimated with perfect certainty, and other aspects of the way the revenue requirement is set may mean investors expect to earn more or less than the cost of capital even if the allowed rate of return equals the cost of capital exactly. However, a commission that sets rates so investors expect to earn the cost of capital on average treats both customers and investors fairly, and acts in the long-run interests of both groups.

B. Business Risk and Financial Risk: Capital Structure and the Cost of Equity

Q12. Please explain briefly the difference between business risk and financial risk.

A12. Business risk is the risk of a company from its line of business if it used no debt financing. When a firm uses debt to finance its assets, the business risk of the assets is shared between the debt holders and the equity holders, but the equity holders bear more of the risk because debt holders have a prior claim on the company's cash flows. Equity holders are residual claimants, which simply means that equity holders get paid last. In other words, the use of debt imposes financial risk on equity holders. Therefore, the goal of selecting a sample is to choose companies whose business risk is judged to be comparable to the regulated company in the proceeding.

Q13. Please explain why it is necessary to report the cost of equity adjusted for capital structure.

A13. Briefly, rate regulation in North America tends to focus on the components of the overall cost of capital, and in particular, on what the "right" cost of equity and capital structure should be. Frequently, there is no consideration of whether the financial risks of the sample companies differ among themselves or differ from the regulated company. The cost of equity estimated using the standard models (e.g., the DCF model or the risk positioning model) reflects both the business and financial risk of the sample companies. However, the overall cost of capital depends primarily on the business the firm is in, i.e., its business risk, while the costs of the debt and equity components depend not only on

this business risk alone but also on the distribution of revenues between debt and equity, i.e., financial risk. The overall cost of capital is thus the more basic concept. As I explain in Appendix C, the overall cost of capital is constant within a broad middle range, but the distribution of the costs and risks among debt and equity is not. Appendix E sets out the principles and procedures on which I rely to adjust the cost of equity to reflect differences in financial risk.

C. IMPLICATIONS FOR ANALYSIS

Q14. Please explain the implications of the relationship between capital structure and the cost of equity in your testimony.

A14. The risk equity holders carry, and therefore the cost of equity, depends on the capital structure. As leverage increases, financial risk increases, and hence the required return on equity increases. An approach that estimates the cost of equity for each of the sample firms without explicit consideration of the market value capital structure (i.e., the financial risk) underlying those costs risks material errors. The costs of equity of the sample companies at their actual market-value capital structures do not necessarily reflect the same degree of financial risk as faced by equity holders in the regulated company, and thus could lead to an unfair rate of return if the sample's cost of equity estimate were simply and mechanically applied to the regulated company's capital structure. I avoid this problem by calculating each sample company's ATWACC using its market value capital structure. Using the sample's average overall cost of capital (i.e., the average of the sample companies' ATWACCs) as an estimate of the regulated company's overall cost of capital, I then determine the corresponding return on equity at each applicant's filed regulatory capital structure. This procedure ensures that the capital structure (i.e., financial risk) and the estimated cost of equity are consistent with the market derived sample information for the regulated company.

Q15. To assess the magnitude of financial risk for a rate regulated company, should you use the market-value or the book-value capital structure?

A15. The market-value capital structure is the relevant quantity for analyzing the cost of equity evidence, which is based on market information.

Q16. Has the need to use market-value capital structures to estimate the cost of equity been widely recognized in the academic community?

A16. Yes. The need to use market-value capital structures to analyze the effect of debt on the cost of equity has been recognized in the financial literature for a long time. For example, the initial reconciliation of the Modigliani-Miller theories of capital structure with the Capital Asset Pricing Model, in Robert S. Hamada, "Portfolio Analysis, Market Equilibrium and Corporate Finance," The Journal of Finance 24: 13-31 (March 1969) works with market-value capital structures. For a more recent presentation of the concept, see, for example, Richard A. Brealey, Stewart C. Myers, and Franklin Allen, *Principles of Corporate Finance*, New York: McGraw-Hill/Irwin 8th ed. (2006) pp. 503-06. Book values may be relevant for some issues, e.g., for covenants on individual bond issues, but as explained in the text, market values are the determinants of the impact of debt on the cost of equity.

Q17. Is the use of market values to calculate the impact of capital structure on the risk of equity incompatible with use of a book-value rate base for a regulated company?

A17. No, no more than it is incompatible to use market-based cost of equity estimation methods (such as DCF or the risk positioning model) with a book value rate base. That is, the cost of capital is the fair rate of return on regulatory assets for both investors and customers. Most regulatory jurisdictions in North America measure the rate base using the net book value of assets, not current replacement value or historical cost trended for inflation, but the jurisdictions still apply market-derived measures of the cost of equity to that net book value rate base.

The issue here is "what level of risk is reflected in that cost of equity estimate?" That equity risk level depends on the sample company's market-value capital structure, not its book-value capital structure. *The risk level measured by the market data would be different if the sample company's market-value capital structure were different.* If the regulated utility has a different capital structure than the market value capital structure for the sample companies, the financial risk is different. Therefore, the estimated cost of equity from the market information, if not adjusted for differences in financial risk, would not correspond to the financial risk of the regulated company.

Q18. Please sum up the implications of this section.

A18. The market risk and, therefore, the cost of equity depend directly on the market-value capital structure of the company or asset in question. It therefore is impossible to compare validly the measured costs of equity of different companies without taking capital structure into account. Capital structure and the cost of equity are unbreakably linked, and any effort to treat the two as separate and distinct questions violates both everyday experience (e.g., with home mortgages as shown in the extended example in Appendix E) and basic financial principles.

Q19. How should a cost of capital analyst implement this principle?

A19. As discussed further in Appendix E, there has been a great deal of financial research on the effects of capital structure on the value of the firm. One of the key conclusions that results from the research is that no narrowly defined optimal capital structure exists within industries, although the typical range of capital structures does vary among industries.[7] Instead, there is a relatively wide range of capital structures within any industry in which fine-tuning the debt ratio makes little or no difference to the value of the firm, and hence to its overall after-tax cost of capital.

Accordingly, analysts should treat the market-value weighted average of the cost of equity and the after-tax current cost of debt, or the "ATWACC" for short,[8] as constant within a broad middle range of capital structures for the industry. Sample evidence should be analyzed to determine the sample's average ATWACC, which can be compared across different firms or industries. The economically appropriate cost of equity for a regulated firm is the quantity that, when applied to the *regulatory* capital structure, produces the same ATWACC. That value is the cost of equity that the sample

[7] An exception is that very high-risk industries should avoid debt entirely, which makes their optimal capital structure zero percent debt.

[8] This quantity typically is called the "weighted-average cost of capital" or "WACC" in finance textbooks. The textbook WACC equals the *market*-value weighted average of the cost of equity and the *after-tax*, *current* cost of debt. However, rate regulation in North America has a legacy of working with another weighted-average cost of capital, the *book*-value weighted average of the cost of equity and the *before-tax*, *embedded* cost of debt. Accordingly, in regulatory settings it's useful to refer to the textbook WACC as the "ATWACC," or "after-tax weighted-average cost of capital." I follow that practice here.

would have had estimation problems aside, if the sample's market-value capital structure had been equal to the regulatory capital structure in question.

Q20. Can you provide a simple example of the calculation of the cost of equity consistent with the market-determined estimate of the sample's average overall cost of capital?

A20. Yes. Consider the following equation to calculate the ATWACC:[9]

$$ATWACC = r_D \times (1 - T_C) \times D + r_E \times E \quad (1)$$

where r_D = market cost of debt,
r_E = market cost of equity,
T_C = corporate income tax rate,
D = percentage of debt in the capital structure, and
E = percentage of equity in capital structure.

The cost of equity consistent with overall cost of capital estimate (ATWACC), the market cost of debt and equity, the marginal corporate income tax rate and the amount of debt and equity in the capital structure can be determined by solving equation (1) for r_E.

III. COST OF CAPITAL METHODOLOGY

Q21. How is this section of your testimony organized?

A21. As noted in *Section II*, I estimate the cost of capital using a sample of comparable risk companies. This section first outlines the steps involved in selecting the benchmark samples, in determining the market-value capital structures, and in estimating the sample companies' costs of debt. It then turns to the procedures for estimating the cost of equity and describes the two cost of equity estimation methodologies used in this testimony, the DCF method and the risk positioning approach. These are the foundations of my cost of capital calculations, which I present in the following section and which I use to derive my recommended costs of equity for the Applicants at their regulatory capital structures.

[9] Note that this equation assumes that only debt and equity are in the capital structure, but it is simple to add preferred equity to the equation.

A. SAMPLE SELECTION CRITERIA

Q22. What is the goal of your sample selection procedures?

A22. The overall cost of capital for a part of a company depends on the risk of the business in which the part is engaged, not on the overall risk of the parent company on a consolidated basis. According to financial theory, the overall risk of a diversified company equals the market-value-weighted average of the risks of its components.

Estimating the cost of capital for the Applicants' regulated assets is the subject of this proceeding. The ideal sample would be a large number of companies that are publicly traded "pure plays" in the electric utility industry for Wisconsin Electric[10] or the natural gas distribution business for Wisconsin Gas. "Pure Play" is an investment term referring to companies with operations only in one line of business. Publicly traded firms, firms whose shares are freely traded on stock exchanges, are ideal because the best way to infer the cost of capital is to examine evidence from capital markets on companies in the given line of business.

In the case of Wisconsin Electric, a sample of integrated electric companies whose operations are concentrated primarily in the regulated portion of the electric industry would be ideal for its regulated electric assets. For Wisconsin Gas, the corresponding ideal sample would consist of pure play companies in the local gas distribution line of business. Unfortunately, the available sample of publicly traded pure play companies meeting these criteria in the U.S. is relatively small for both the electric industry and natural gas LDC line of business at this time. Moreover, some of the companies that do meet these criteria suffer from data problems that may make their cost of capital estimates unreliable. For this reason, my standard selection procedures are also designed to exclude companies which have characteristics which may result in unreliable cost of capital estimates. Specifically, I require that data from S&P (or Moody's), *Value Line*,

[10] As noted earlier, about 10 percent of Wisconsin Electric's assets are devoted to providing natural gas distribution service. Theoretically, those assets could have a different level of business risk than the integrated electric assets, which in turn would require an alternative cost of capital estimate. However, in this proceeding the estimated ATWACCs for the natural gas LDC and electric utility samples are nearly identical, which means that there is no material error in applying the same cost of capital for all of Wisconsin Electric's regulated assets.

and Bloomberg be available for all sample companies. Moreover, companies are required to evidence a high degree of regulated operations, have no significant merger activity in the previous five years, and have no recent dividend cuts or other activity that could cause the growth rates or beta estimates to be biased.

B. CAPITAL STRUCTURE & THE COST OF DEBT

1. Market-Value Capital Structure

Q23. What capital structure information do you require?

A23. For reasons discussed in Appendix E, explicit evaluation of the market-value capital structures of the sample companies is vital for a correct interpretation of the market evidence on the return on equity. This requires estimates of the market values of common equity, preferred equity and debt, and the current market costs of preferred equity and debt.

Q24. Please describe how you calculate the market values of common equity, preferred equity and debt.

A24. I estimate the market value capital structure for each sample company by estimating the market values of common equity, preferred equity and debt from the most recent publicly available data. The details are in Appendix B.

Briefly, the market value of common equity is the price per share times the number of shares outstanding. For the risk positioning approach, I use the average closing price over last five trading days of each year to calculate the market value of equity for the year. I then calculate the average capital structure over the corresponding five-year period used to estimate the "beta" risk measures for the sample companies.[11] This procedure matches the estimated beta to the degree of financial risk present during its estimation period. In the DCF analyses, I use the average closing stock price over the 15 trading days ending on the day that the earnings growth rate forecasts are obtained from Bloomberg.[12]

[11] *Value Line* uses five years of historical data to estimate its forecasted betas.

[12] Forecasts were obtained on April 9, 2007 for all companies in the both samples.

The market value of debt is estimated at its book value adjusted by the difference between the "estimated fair (market) value" and the "carrying cost" of long-term debt reported in each company's 10-K.[13] The market value of preferred stock for the samples is set equal to its book value because the market values and book values do not differ much and because the percent of preferred stock in the capital structures of the sample companies is relatively small compared to the debt and common equity components.

2. Market Costs of Debt and Preferred Equity

Q25. How do you estimate the current market cost of debt?

A25. The market cost of debt for each company in the DCF analysis is the current yield reported by Bloomberg for a public utility company bond corresponding to the sample company's current debt rating as classified by S&P. The risk positioning analysis, on the other hand, uses the current yield of a utility bond that corresponds to the five-year average debt rating of each company so as to match consistently the horizon of information used by *Value Line* to estimate company betas.

Q26. How do you estimate the market cost of preferred equity?

A26. For each company with preferred stock, the cost of preferred equity for each company is set equal to the yield on an index of preferred stock as reported in the Mergent Bond Record corresponding to the S&P rating of that company's debt.

3. Risk-Free Interest Rate Forecast

Q27. How do you obtain the forecasts of the risk-free interest rates over the period the utility rates set here are to be in effect?

A27. I obtain these forecast rates using data provided by Bloomberg. In particular, I use the reported government debt yields from the "constant maturity series". This information is displayed in Panels A and B of Table No. MJV-9.

[13] The book value of debt from Bloomberg includes all interest-bearing financial obligations that are not current and includes capitalized leases and mandatory redeemable preferred and trust preferred securities in accordance with FASB 150 effective June 2003. See Bloomberg definition of long-term debt for additional detail.

Q28. What values do you use for the short-term and long-term risk-free interest rates?

A28. I use a value of 3.8 percent for the short-term risk-free interest rate and a value of 4.9 percent for the long-term risk-free interest rate as the benchmark interest rates in the equity risk premium analyses. These forecasts are constructed by using historical yield curve data to find the long-run average implied term premia on government securities, and combining these with recent yield curve data. Details of their calculation can be found in the Workpapers to Table No. MJV-9.

Q29. How did you determine a representative tax rate to use in your cost of capital estimation?

A29. The Applicants provided estimated marginal tax rates for each company. For Wisconsin Electric the estimated 2008 marginal tax rate is 39.8 percent, and for Wisconsin Gas it is 40.0 percent.

C. COST OF EQUITY METHODS

Q30. How do you estimate the cost of equity for your sample companies?

A30. Recall the definition of the cost of capital from the outset of my testimony: *the expected rate of return in capital markets on alternative investments of equivalent risk*. My cost of capital estimation procedures address three key points implied by the definition:

1. Since the cost of capital is an expected rate of return, it cannot be directly observed; it must be inferred from available evidence.

2. Since the cost of capital is determined in capital markets (e.g., the New York Stock Exchange), data from capital markets provide the best evidence from which to infer it.

3. Since the cost of capital depends on the return offered by alternative investments of equivalent risk, measures of the risks that matter in capital markets are part of the evidence that needs to be examined.

Q31. How does the above definition help in cost of capital estimation?

A31. The definition of the cost of capital recognizes a tradeoff between risk and expected return, plotted above in Figure 1, the security market line. Cost of capital estimation methods take one of two approaches: (1) they try to identify a comparable-risk sample of

companies and to estimate the cost of capital directly; or (2) they establish the location of the security market line and estimate the relative risk of the security, which jointly determine the cost of capital. In terms of Figure 1, the first approach focuses directly on the vertical axis, while the second focuses both on the security's position on the horizontal axis and on the position of the security market line.

The first type of approach is more direct, but ignores the wealth of information available on securities not thought to be of precisely comparable risk. The "discounted cash flow" or "DCF" model is an example. The second type of approach, sometimes known as "equity risk premium approach," requires an extra step, but as a result can make use of information on all securities, not just a very limited subset. The Capital Asset Pricing Model ("CAPM") is an example. While both approaches can work equally well if conditions are right, one may be preferable to the other under a given set of circumstances. In particular, approaches that rely on the entire security market line (e.g., the risk positioning model) are less sensitive to deviations from the assumptions that underlie the model, all else equal. In this proceeding, I examine sample evidence from both the DCF and risk positioning models.

1. The Risk Positioning Approach

Q32. Please explain the risk positioning method.

A32. The risk positioning method estimates the cost of equity as the sum of a current interest rate and a company specific risk premium. It is therefore sometimes also known as the "risk premium" approach. This approach may sometimes be applied informally. For example, an analyst or commission may check the spread between interest rates and what is believed to be a reasonable estimate of the cost of capital at one time, and then apply that spread to changed interest rates to get a new estimate of the cost of capital at another time.

More formal applications of the risk positioning approach take full advantage of the security market line depicted in Figure 1: they use information on all securities to identify the security market line and derive the cost of capital for the individual security based on that security's relative risk. This reliance on the entire security market line

makes the method less vulnerable to the kinds of problems that arise for the DCF method, which relies on one stock at a time. The risk positioning approach is widely used and underlies most of the current research published in academic journals on the nature, determinants and magnitude of the cost of capital.

Section I of Appendix C to this testimony provides more detail on the principles that underlie the risk positioning approach. *Section II* of Appendix C provides the details of the risk positioning approach empirical estimates I obtain.

Q33. How are the "more formal" applications of risk positioning approach implemented?

A33. The first step is to specify the current values of the parameters that determine the security market line. The second is to determine the security's or investment's relative risk. The third is to specify exactly how the parameters combine to produce the security market line, so the company's cost of capital can be calculated based on its relative risk. All of these elements and how they relate are usefully formulated in the framework of the CAPM.

a) The Capital Asset Pricing Model

Q34. Please start with the CAPM, by describing the model.

A34. As noted above, modern models of capital market equilibrium express the cost of equity as the sum of a risk-free rate and a market risk premium. The CAPM is the longest-standing and most widely used of these theories. The CAPM states that the cost of capital for an investment, *s*, (e.g., a particular common stock) is given by the following equation:

$$k_s = r_f + \beta_s \times MRP \qquad (2)$$

where k_s is the cost of capital for investment *s*; r_f is the risk-free rate, β_s is the beta risk measure for the investment *s*; and *MRP* is the market risk premium.

The CAPM relies on the empirical fact that investors price risky securities to offer a higher expected rate of return than safe securities do. It says that the security market line starts at the risk-free interest rate (that is the return on a zero-risk security, the y-axis

intercept in Figure 1, equals the risk-free interest rate). Further, it says that the risk premium over the risk-free rate equals the product of beta and the risk premium on a value-weighted portfolio of all investments, which by definition has average risk.

b) The Empirical Capital Asset Pricing Model

Q35. What other equity risk premium model do you use?

A35. Empirical research has long shown that the CAPM tends to overstate the actual sensitivity of the cost of capital to beta: low-beta stocks tend to have higher risk premia than predicted by the CAPM and high-beta stocks tend to have lower risk premia than predicted. A number of variations on the original CAPM theory have been proposed to explain this finding, but this finding can also be used to estimate the cost of capital directly, using beta to measure relative risk without simultaneously relying on the CAPM.

The second model makes use of these empirical findings. It estimates the cost of capital with the equation, where α is the "alpha" adjustment of the risk-return line, a constant,

$$k_s = r_f + \alpha + \beta_s \times (MRP - \alpha) \quad (3)$$

and the other symbols are defined as above. I label this model the Empirical Capital Asset Pricing Model, or "ECAPM." The alpha adjustment has the effect of increasing the intercept but reducing the slope of the security market line in Figure 1, which results in a security market line that more closely matches the results of empirical tests.

Q36. Why is it appropriate for you to use the empirical CAPM?

A36. Although the CAPM is still the most widely used cost of capital estimation model, it has not been completely satisfactory as an empirical model; however, its short-comings are directly addressed by the ECAPM. The ECAPM recognizes the consistent empirical observation that the CAPM underestimates (overestimates) the cost of capital for low (high) beta stocks. In other words, the ECAPM is based on the recognition that the actual slope of the risk-return tradeoff is flatter than predicted and the intercept higher based upon repeated empirical tests of the CAPM. The alpha parameter (α) in the ECAPM adjusts for this fact. The difference between the CAPM and the type of relationship identified in the empirical studies is depicted in Figure 2.

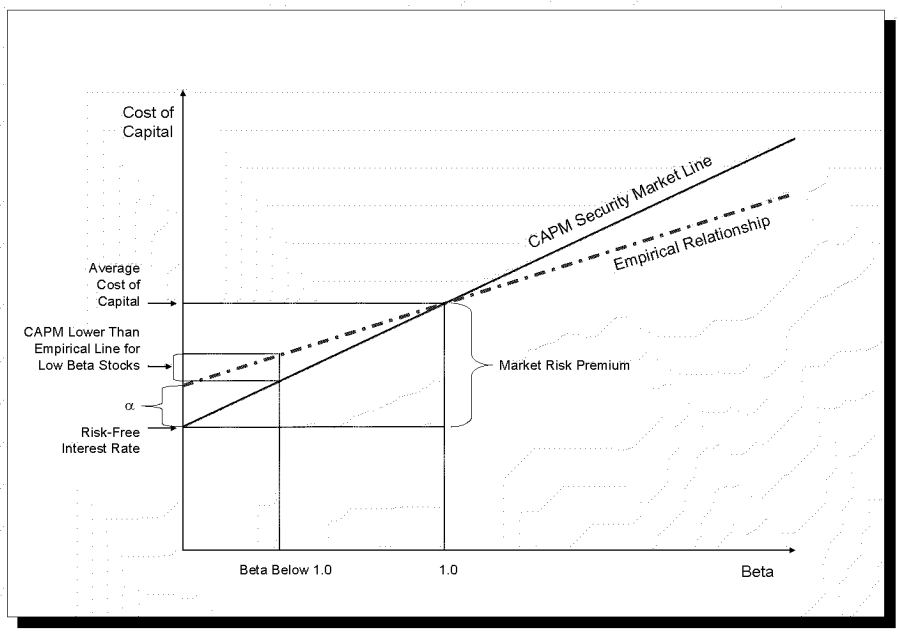

Figure 2: The Empirical Security Market Line

Research supports values for α of one to seven percent when using a short-term interest rate. I use baseline values of α of 2 percent for the short-term risk-free rate and 0.5 percent for the long-term risk-free rate. I also conduct sensitivity tests for different values of α. For the short-term risk-free rate I use values for α of 1, 2 and 3 percent. For the long-term risk-free rate, the corresponding α values are 0, 0.5 and 1.5 percent. These values are lower than would be justified by the magnitude of the correction revealed in the tests of the CAPM. The α values are lower when using the long-term risk-free rate because use of a long-term risk-free rate incorporates some of the desired effect of using the ECAPM. That is, the long-term risk-free rate version of the security market line has a higher intercept and a flatter slope than the short-term risk-free version which has been extensively tested. Thus, I do not need to make the same degree of refinement when I use the long-term risk-free rate. Please see Table No. MJV-C1 in Appendix C for a summary of the empirical evidence on the size of the required adjustment necessary to better match the results of the empirical tests.

2. Discounted Cash Flow Method

Q37. Please describe the discounted cash flow approach.

A37. The DCF model takes the first approach to cost of capital estimation, i.e., to attempt to estimate the cost of capital in one step. The method assumes that the market price of a stock is equal to the present value of the dividends that its owners expect to receive. The method also assumes that this present value can be calculated by the standard formula for the present value of a cash flow stream:

$$P = \frac{D_1}{(1+k)} + \frac{D_2}{(1+k)^2} + \frac{D_3}{(1+k)^3} + \cdots + \frac{D_T}{(1+k)^T} \quad (4)$$

where "P" is the market price of the stock; "D_t" is the dividend cash flow expected at the end of period t (i.e., subscript period 1, 2, 3 or T in the equation); "k" is the cost of capital; and "T" is the last period in which a dividend cash flow is to be received. The formula just says that the stock price is equal to the sum of the expected future dividends, each discounted for the time and risk between now and the time the dividend is expected to be received.

Very often, when the DCF is applied in regulatory proceedings, very strong (i.e., unrealistic) assumptions are used that yield a simplification of the standard formula, which then can be rearranged to estimate the cost of capital. Specifically, it is assumed that investors expect a dividend stream that will grow *forever* at a steady rate, and if so, the market price of the stock will be given by a very simple formula,

$$P = \frac{D_1}{(k-g)} \quad (5)$$

where "D_1" is the dividend expected at the end of the first period, "g" is the perpetual growth rate, and "P" and "k" are the market price and the cost of capital, as before. Equation (5) is a simplified version of equation (4) that can be solved to yield the well known "DCF formula" for the cost of capital:

$$k = \frac{D_1}{P} + g = \frac{D_0 \times (1+g)}{P} + g \quad (6)$$

where "D_0" is the current dividend, which investors expect to increase at rate g by the end of the next period, and the other symbols are defined as before. Equation (6) says that if equation (5) is correct, the cost of capital equals the expected dividend yield plus the (perpetual) expected future (forever constant) growth rate of dividends. I refer to this as the simple DCF model. Of course, the "simple" model is simple because it relies on very strong (i.e., very unrealistic) assumptions.

Q38. Are there other versions of the DCF models besides the "simple" one?

A38. Yes. The constant growth rate DCF model requires that dividends and earnings grow at the same rate for companies that earn their cost of capital on average.[14] It is inconsistent with the theory on which the model is based to have different growth rates in earnings and dividends over the period when growth is assumed to be constant. If the growth in dividends and earnings were expected to vary over some number of years before settling down into a constant growth period, then it would be appropriate to estimate a multistage DCF model. In the multistage model, earnings and dividends can grow at different rates, but must grow at the same rate in the final, constant growth rate period. A difference between forecasted dividend and earnings rates therefore is a signal that the facts do not fit the assumptions of the simple DCF model.

So, I consider a variant of the DCF model that relies on slightly less strong assumptions in that it allows for varying dividend growth rates in the near term before assuming a perpetual growth rate beginning in year eleven. I use the forecast growth of GDP as the forecast of the long-term growth rate, i.e. year eleven on. This is a "multistage" variant

[14] Why must the two growth rates be equal in a steady-growth DCF model? Think of earnings as divided between reinvestment, which funds future growth, and dividends. If dividends grow faster than earnings, there is less investment and slower growth each year. Sooner or later dividends will equal earnings. At that point, growth is zero because nothing is being reinvested (dividends are constant). If dividends grow slower than earnings, each year a bigger fraction of earnings are reinvested. That makes for ever faster growth. Both scenarios contradict the steady-growth assumption. So if you observe a company with different expectations for dividend and earnings growth, you know the company's stock price and its dividend growth forecast are inconsistent with the assumptions of the steady-growth DCF model.

of the DCF method. The DCF models are described in detail in Section I.A of Appendix D. (*Section II* of Appendix D provides the details of my empirical DCF results.)

Q39. What are the merits of the DCF approach?

A39. The DCF approach is conceptually sound if its assumptions are met, but can run into difficulty in practice because those assumptions are so strong[15], and hence so unlikely to correspond to reality. Dividends, earnings and prices are unlikely to grow at a constant rate literally forever. Two conditions other are also well known to be necessary for the DCF approach to yield a reliable estimate of the cost of capital: the variant of the present value formula that is used must actually match the variations in investor expectations for the growth of dividends, and the growth rate(s) used in that formula must match current investor expectations. Less frequently noted conditions may also create problems (see Appendix D for details).

Q40. Is estimating the "right" dividend growth rate the most difficult part for the implementation of the DCF approach?

A40. Yes. Finding the right growth rate(s) is the usual "hard part" of a DCF application. The original approach to estimation of g relied on average historical growth rates in observable variables, such as dividends or earnings, or on the "sustainable growth" approach, which estimates g as the average book rate of return times the fraction of earnings retained within the firm. But it is highly unlikely that these historical averages over periods with widely varying rates of inflation and costs of capital will equal current growth rate expectations. As discussed above, this is particularly true for the electric industry at present because the ultimate structure of the industry is uncertain. The movement toward restructuring has stalled and, in some locations, a reversal of the process is being considered. In addition, there is uncertainty associated with the possible imposition of new environmental regulations. Although there has been less turmoil in the natural gas LDC line of business, there have been a number of mergers and acquisitions as well as some accounting irregularities in recent years due in part due to the increased volatility of natural gas prices. Uncertainty generally leads to lower earnings growth

[15] In this context "strong" means that the assumption is unlikely to match reality and that it also has a substantial impact on the model's results.

estimates. These facts would not be a description of the stable conditions necessary for the reliable implementation of the DCF model for either sample.

IV. COST OF CAPITAL ESTIMATES

A. WISCONSIN ELECTRIC

1. Company Background

Q41. Please describe Wisconsin Electric.

A41. Wisconsin Electric operates in three operating segments: 1) an electric utility, 2) a natural gas utility, and 3) a steam utility, but about 90 percent of the assets are dedicated to providing service as an integrated electric utility. Wisconsin Electric serves approximately 1,102,200 electric customers in Wisconsin and the Upper Peninsula of Michigan, approximately 452, 600 gas customers in Wisconsin, and 460 steam customers in metropolitan Milwaukee. Wisconsin Electric has been investing in natural gas fired and coal fired electric generating facilities, upgrading existing electric generating facilities, and investing in upgrades in existing energy distribution systems to improve its supply and reliability of electricity service. Wisconsin Electric faces fluctuating prices in the natural gas market but has in place a fuel cost adjustment clause to help hedge price fluctuations. The company also supports a state supported energy conservation program. The company has an unsecured debt rating of A- from S&P.

2. Sample Selection

Q42. How did you select your sample of electric utilities?

A42. The goal was to create a sample of companies whose primary business is as a regulated electric utility with business risk generally similar to that of Wisconsin Electric. To construct this sample, I formed a universe of 61 companies by the electric companies under East, Central and West categories listed in *Value Line*. From this group, companies were first eliminated if their operating regions were outside of the continental USA or if they were primarily or solely engaged in generation and/or transmission. I

then applied my standard selection criteria outlined earlier to remove companies that have characteristics that may bias the cost of capital estimates.

Specifically, I required the sample companies to have an investment grade credit rating (i.e., BBB- or above), have had no dividend cuts in the past five years, have revenues of at least $300 million and have five years of historical data in Bloomberg. I only accepted companies whose share of regulated assets was estimated to be at least "Mostly Regulated" as classified by the Edison Electric Institute ("EEI").[16] I also required that the companies have engaged in no major merger or acquisition during the last five years. A total of nine companies met all of these requirements: Cleco Corp, Consolidated Edison, Empire District Electric, Entergy Corp, MGE Energy, NSTAR, Pinnacle West Capital Corp, PPL Corp, and Southern Corp. Additional details on the sample selection process can be found in Appendix B. Characteristics of the sample companies are outlined in Table 1 below.

[16] EEI has three classifications for electric utilities based upon the percentage of total assets that are regulated. The categories are Regulated (> 80% regulated), Mostly Regulated (50-80% regulated) and Diversified (< 50% regulated). See *EEI 2006 Financial Review*, p. 24.

Table 1: Benchmark Regulated Electric Sample

Company	Business Activities [1]	Revenue (2006) ($MM) [2]	Regulated Assets (2006) [3]	Market Cap. (2006) ($MM) [4]	S&P Bond Rating (2007) [5]	Estimated Beta [6]	Long-Term Growth Estimate [7]

Q43. Table 1 lists the characteristics of the sample. Do you have any concerns with any of the companies in the benchmark electric sample?

A43. Possibly. Although there was not enough merger and acquisition activity to eliminate them from the sample, three of nine companies had more activity over the past five years than the others: Cleco, Empire District Electric and Entergy. Cleco Corp.'s beta is also

substantially higher at 1.30 than any of the other sample companies'. Two sample companies, Empire District and MGE Energy, are smaller companies compared to the others in the sample, but both have a book value of about a $1 billion making them "large" by most standards. PPL Corp and MGE Energy are classified as Mostly Regulated which means that a substantial portion of their assets are not subject to regulation. A potential problem for the DCF estimates is that sample companies growth rate forecasts vary substantially company-to-company, and some companies have only one or two analyst forecasts. As noted earlier, this may be an indication that the industry conditions necessary for the reliable application of the DCF model are not fully met at this time. Recall that the DCF model requires stable industry conditions so that dividends, earnings, stock prices etc. are all growing at a constant rate.

3. Relative Risk of the Sample and Wisconsin Electric

Q44. Please summarize the general risk characteristics of the companies in the sample and those of Wisconsin Electric?

A44. The sample consists of six integrated utilities and three companies with a provider of last resort ("POLR) obligation operating in states that have already transitioned to market based rates. A summary of their risk characteristics is provided in Table 2 below.

Table 2: Risk Factors of Electric Sample

	States Served	Subsidiary Utilities Providing Service to State	POLR	Rate Cap for POLR Utilities	Fuel Cost Adjustment†	S&P Business Profile‡
Restructured Electricity Markets						
Consolidated Edison Inc	NY	Con Edison of New York	Yes	No	Yes	2
	NJ	Orange and Rockland	Yes	No	No	
	PA		Yes	No	No	
NSTAR	MA	NSTAR	Yes	No	Yes	1
PPL Corp	PA	PPL Electric Utilities Co	Yes	Yes [until 2009]	No	7
Restructuring-in-process Markets						
Pinnacle West Capital Corp [a]	AZ	Arizona Public Service Co	No	-	Yes	6
Integrated Electricity Markets						
Cleco Corp	LA	Cleco Power	-	-	Yes	6
Empire District Electric Co	KS	Empire District Electric Co	-	-	Yes	-
	MO		-	-	No	
	OK[c]		-	-	Yes	
	AR[c]		-	-	Yes	
Entergy Corp	AR[c]	Entergy Arkansas	-	-	Yes	6
	TX	Entergy Gulf States	-	-	Yes	
	LA	Entergy Louisiana / Entergy Gulf States / Entergy New Orleans[b]	-	-	Yes

Company 10-K's, 2006.

Q45. How does the risk of the sample compare to the risk of Wisconsin Electric?

A45. In general, the sample appears to be of similar risk to Wisconsin Electric. Six of the nine companies are integrated utilities, and all but Empire electric have some form of fuel-cost adjustment mechanisms covering the bulk of their operations. Three sample companies have a POLR obligation, and they are in states that have moved to market based rates. As a result, they face a different kind of regulatory uncertainty than does Wisconsin Electric, but all sample companies face the uncertainty associated with the recent the volatility of fuel prices. Consumers have demonstrated an aversion to highly volatile energy prices, so regulatory authorities may be reluctant to allow full recovery of energy prices that are too variable.

Depending upon the recovery mechanism for the costs of providing POLR service, the risks faced by electric distribution companies with a POLR obligation may be greater than or less than those of an integrated utility. The biggest risk difference between the two is that integrated utilities own or contract for the generation capacity to meet the power needs of their customers. Although they are still exposed to changes in fuel prices as well as the construction and operating risk of owning generation, they have a natural hedge against volatile energy prices through their ownership of generation assets. POLR companies, on the other hand, are potentially exposed to changes in market prices not related to the volatility of fuel prices, because they must purchase power at market rates.

4. Electric Sample Cost of Capital Estimates

Q46. Please summarize the results of the risk positioning and DCF methodologies in estimating the average cost of capital for the benchmark sample and the implications for Wisconsin Electric's cost of equity?

A46. Table 3 summarizes the sample average ATWACCs derived from risk positioning and DCF models along with the implied cost of equity for Wisconsin Electric at its regulatory capital structure with 55 percent equity.

Table 3: Cost of Equity Estimates - Benchmark Electric Sample

Sources and Notes:

* For the US Electric Sample , Risk Positioning data from Table No. MJV-12 and DCF data from Table No. MJV-8.

[1] Electric sample consists of Cleco Corp, Consolidated Edison, Empire District Electric, Entergy Corp, MGE Energy, NSTAR, Pinnacle West Capital Corp, PPL Corp, and Southern Co.

[2] See Appendix C and D for details on Risk Positioning and DCF parameters used in estimates.

The two risk positioning models (CAPM and ECAPM) are estimated for each horizon, with the long-term estimates utilizing two values of the ECAPM parameter (0.5% and 1.5%), and the short-term estimates utilizing three values of the ECAPM parameter (1%, 2%, and 3%). I therefore obtain three long-term and four short-term estimates of each sample company's cost of equity. The results are displayed in Table MJV-10, Panel A (long-term risk-free rate) and Panel B (short-term risk-free rate). Next, the cost of equity estimates are combined with each company's estimated cost of debt and preferred equity to calculate the company's ATWACC using each company's market value capital structure as weights. These calculations and the resulting sample average ATWACCs are presented in Table No. MJV-11. Panels A-C rely on the cost of equity estimates from the long-term version of the model, while Panels D-G utilize the estimates from the short-term version of the model. The sample average ATWACC and cost of equity at Wisconsin Electric's 55 percent equity capital structure for each risk positioning cost of equity estimate are displayed in Table No. MJV-12. These results are summarized in Table 3 above.

Q47. How did you determine that the appropriate capital structure for Wisconsin Electric has 55 percent equity?

A47. I reviewed Exhibit MLW-2, Schedule 1, page 3 of 5 of Company Witness Mary L. Wolter on the capital structure of Wisconsin Electric. I adjusted the total long-term capital of the company by subtracting short-term debt and the imputed debt for the company's purchased power contracts. I then recalculated the percentages of debt, preferred and common equity in the capital structure. The calculations are in Workpaper #4 to Table No. MJV-4. These calculations insure that the measures of financial risk for the sample and Wisconsin Electric are comparable.

Q48. What are the DCF estimates for the benchmark electric sample?

A48. For each sample company, cost-of-equity estimates are calculated for the two versions of the DCF method, the simple DCF model and multistage DCF model. The DCF estimates for each company are displayed in Table No. MJV-6, Panel A (simple DCF) and Panel B (multistage DCF). The sample average ATWACC for each method is calculated in Table No. MJV-7 and the resulting sample average ATWACC is used in Table No. MJV-8 to derive the return on equity at Wisconsin Electric's 55 percent equity capital structure. These results are shown in Table 3 above, along with the sample average ATWACC numbers. Table 3 shows the estimated cost of equity to be 12.5 percent when using the simple DCF model and 10.6 percent from the multistage DCF model. The estimates from the simple DCF exceed the estimates from both the long-term and short-term risk positioning models, but the estimates from the multistage DCF model are somewhat lower than all of the risk positioning estimates.

B. WISCONSIN GAS

1. Company Background

Q49. Please describe Wisconsin Gas.

A49. Wisconsin Gas is the largest natural gas utility in Wisconsin, operating throughout the state, including the city of Milwaukee. In 2006, the company delivered approximately 1,216.3 million gas therms to 588,800 gas customers, generating $830 million in revenue.

The company faces competition in the form of alternate fuels, especially in instances where large industrial or commercial customers have dual-fuel capabilities. Wisconsin Gas contracts with various pipelines located in Oklahoma, Texas, the Gulf of Mexico and Canada, reflecting a desire to diversify based upon geographic location. The company has also contracted for substantial storage capacity, primarily in Michigan, allowing it flexibility in terms of customer demand and pricing. The company has a PSCW approved gas price hedging program and a fuel cost adjustment clause, but it has no weather or volume adjustment clauses. The S&P rates its unsecured senior debt at A-.

2. Sample Selection

Q50. How did you select your sample of natural gas LDCs?

A50. The goal was to create a sample of companies whose primary business is as a regulated natural gas LDC with business risk generally similar to that of Wisconsin Gas. I considered the universe of 23 companies classified by the *Value Line Investment Survey Plus* as natural gas LDCs, and added Vectren Corporation to my sample because it is often viewed as a natural gas LDC. Vectren is involved in both gas and electric distribution activities, but now obtains a substantial amount of income from its gas distribution operations.[17] This company is also covered by *Value Line*, but is classified as an Electric Utility due to its regulated electric operations.

Companies were first eliminated if their operating regions were outside of the continental USA. I then applied my standard selection criteria to narrow the sample to those companies likely to have reliable cost of equity estimates. This resulted in a benchmark sample of ten companies which are outlined in Table 4. Additional details on the sample selection process can be found in Appendix B.

[17] Vectren Utility Holdings, Inc.'s 2006 10K reveals that about 45.4 percent of its income is from regulated gas distribution activities and 45.5 percent from regulated electric operations. Because it has a substantial amount of regulated electric activity, I exclude it from the sub-sample of companies I consider to be the most representative of the natural gas distribution line of business and to be most free of characteristics that may bias cost of equity estimates (see below).

Table 4: Benchmark Regulated Gas LDC Sample

3. The Gas LDC Sub-Sample

Q51. Why do you advocate summarizing the cost of capital estimates from a sub-sample of the gas LDC companies as well as for the full sample?

A51. Although the sample selection criteria are designed to screen out any company that has characteristics that may bias the cost of equity estimates, some of the sample companies are better than others. For example, although still investment grade, Southwest Gas is at the bottom of the scale of investment grade credit ratings and has a relatively low average equity thickness over the past five years – 40.1 percent compared to 61.8 percent for the remaining companies. Closer investigation shows that Southwest Gas's capital structure has been shifting rapidly toward equity over the last five years, with a level of about 50 percent over the most recent two years. This instability suggests a potential reliability problem for estimates of this company's cost of capital. The Laclede Group's market cap of $688 million is a bit smaller than the average of the group, but with revenues of more than $1.5 billion, it is still a large company. In 2006, Piedmont Natural Gas restated some portions of its 2003-2005 financial reports. Although this can generally lead to less reliable estimates from the equity estimation models, the restatements were not caused by fraudulent activities but were due to an accounting error in the classification of hedging amounts. This type of reclassification would not be expected to change the value of the firm and prices did not show any erratic behavior in the period surrounding the announcement of this reclassification. A potential concern for the DCF estimates is that the industry has experienced a sustained level of merger and acquisition activity over the last five years that has implication for the stability of the industry necessary for the reliable application of the DCF model. Due to the concerns with the sample, I also report the results for a sub-sample of the gas LDC sample that consists of companies with no material data issues.

4. Relative Risk of the Sample and Wisconsin Gas

Q52. Could you please summarize the general characteristics of the companies in the sample and those of Wisconsin Gas?

A52. Yes. The sample consists of ten gas LDCs with risk characteristics generally similar to those of Wisconsin Gas. Like Wisconsin Gas, they all have fuel-cost adjustment clauses which either remove or significantly reduce their exposure to this risk. In their 10-Ks, all sample companies report that they engage in hedging activities to further reduce this risk. In addition, seven of the ten companies have weather adjustment clauses which Wisconsin Gas does not have.

Table 5: Risk Characteristics of the Gas LDC Sample

[6] S&P Business Profile as published on April 28, 2006 in S&P's *U.S. Utility and Power Ranking List*

Q53. How does the risk of the sample compare to the risk of Wisconsin Gas's distribution operations?

A53. In general, the benchmark sample has comparable business risk to Wisconsin Gas.

5. Gas LDC Sample Cost of Capital Estimates

Q54. Please summarize the results of the risk positioning and DCF methodologies in estimating the average cost of capital for the sample and the implications for Wisconsin Gas's cost of equity?

A54. Table 6 below summarizes the risk positioning and DCF cost of equity estimates and the resulting sample average ATWACC estimates for the gas LDC sample, along with the implied cost of equity for Wisconsin Gas at a regulatory capital structure with 52 percent equity.

Q55. How were the cost of equity estimates derived from the risk positioning approach for the benchmark gas LDC sample?

A55. In exactly the sample manner as for the electric sample, the two risk positioning models (CAPM and ECAPM) are estimated for each horizon, with the long-term estimates utilizing two values of the ECAPM parameter (0.5% and 1.5%), and the short-term estimates utilizing three values of the ECAPM parameter (1%, 2%, and 3%). The risk positioning cost of equity estimates for the gas LDC sample are displayed in Table No. MJV-20, Panels A and B. The cost of equity estimates are subsequently combined with each company's estimated cost of debt and preferred equity to calculate the company's ATWACC using each company's market value capital structure. These calculations and the resulting sample average ATWACC are presented in Table No. MJV-21. Panels A-C of Table No. MJV-21 rely on the cost of equity estimates from the long-term version of the model, while Panels D-G utilize the estimates from the short-term version of the model. The sample average ATWACC and cost of equity at Wisconsin Energy's 52 percent equity capital structure for each cost of equity estimation methods are displayed in Table No. MJV-22. These results are summarized in Table 6 below.

Table 6: Cost of Equity Estimates - Benchmark Gas LDC Sample

Sources and Notes:

* For the MJV US Gas LDC Sample , Risk Positioning data from Table No. MJV-22 and DCF data from Table No. MJV-17.

[1] , [2] The Gas LDC sample consists of Atmos Energy Corp, Laclede Group Inc, Northwest Natural Gas Co, Piedmont Natural Gas Co, South Jersey Industries Inc, Southwest Gas Corp, WGL Holdings Inc, AGL Resources Inc, Vectren Corp., and New Jersey Resources. The sub-sample includes only Laclede Group Inc, Northwest Natural Gas Co, Piedmont Natural Gas Co, and WGL Holdings Inc.

[3] See Testimony, Section IV.C for details on Risk Positioning and DCF parameters used in estimates.

Q56. What are the DCF estimates for the gas LDC sample?

A56. For each sample company, cost-of-equity estimates are calculated for the two versions of the DCF method. The DCF estimates for each company are displayed in Table No. MJV-17, Panel A (simple DCF) and Panel B (multistage DCF). The sample average ATWACC for each method is calculated in Table No. MJV-18 and the resulting sample average ATWACC is used in Table No. MJV-19 to derive returns on equity at Wisconsin Gas's 52 percent equity capital structure. These results are shown in Table 6 above, along with the sample average ATWACC numbers. Table 6 shows a cost of equity of 9.3 percent when using the simple DCF model but 10.0 percent from the multistage DCF model for the full sample. The corresponding results for the more reliable sub-sample are 9.5 percent and 10.5 percent. The variation in estimates from the simple DCF compared to the multistage model likely reflect the unusual events in the industry and are not likely to be reliable estimates of the cost of capital at this time.

V. CONCLUSIONS

Q57. What are your conclusions from the DCF model regarding the cost of equity for the Applicants?

A57. As discussed above, the conditions necessary for the completely reliable implementation of the DCF model are not likely to exist for the electric utility and the gas LDC industries at this time. For example, the company specific growth rate forecasts displayed in Table 1 and Table 4 vary substantially company to company, but for an industry operating in stable conditions, you would expect to see very similar forecast growth rates.

Review of Table No. MJV-6, Panel A and Table No. MJV-17, Panel A shows that the simple DCF cost of equity estimates are highly variable. For the electric sample, the estimates range from a low of 7.4 percent to a high of 16.3 percent. The multistage estimates are much less variable, but still have a relatively wide range from a low of 7.7 percent to a high of 10.7 percent. For the gas LDC sample, the simple DCF estimates are also quite variable ranging from a low of 6.5 percent to a high of 10.1 percent. The range for the multistage DCF is 7.4 percent to 9.8 percent. In addition, given the generally similar business risk of the two industries, I would expect that the overall cost of capital for the two industries would be very similar, but that is not the result from the DCF model. For example, the ATWACC from the simple DCF model for the electric sample is 8.5 percent compared to 6.5 percent for the gas LDC sample (6.7 percent for the sub-sample).[18] The results for the more reliable multistage DCF model are closer, 7.4 percent for the electric sample compared to 6.9 percent for the full gas LDC sample (7.1 percent for the sub-sample). (See Tables 3 and 6 above) These results are in stark contrast to the more consistent results for the two samples from the risk positioning model.

In my view, these results confirm that the conditions for the completely reliable implementation of the DCF model are not present for either sample at this time. I therefore place little weight on the DCF results for either sample.

[18] Note that the comparison is between the estimated overall costs of capital because those estimates consider both the business and financial risk of the sample companies.

Q58. Do you have any general comments regarding the results of the risk positioning models?

A58. The risk positioning results for the two samples are summarized above in Table 3 and Table 6. For both samples, the estimates based upon the short-term risk-free rate are higher on average than the estimates using the long-term risk-free rate, partially because the yield curve is currently flat or slightly inverted, i.e., the yield on short-term Treasury bills exceeds the yield on long-term Treasury bonds. Table No. MJV-9, Panel A shows that 30-day Treasury bills are currently yielding 5.16 percent compared to only 4.90 percent for long-term Treasury bonds. This relationship between the yield on short-term and long-term Treasury securities is unusual. Yields on long-term Treasury bonds have averaged about 150 basis points more than yields on 30-day Treasury bills over the last 80 years. (See Workpaper #1, Panel B to Table No. MJV-9) The yield on short-term Treasury bills reflects the efforts by the Federal Reserve ("Fed") to prevent the rate of inflation from increasing any further. If the Fed believes that inflation is not yet contained, short-term rates are likely to increase further. On the other hand, if inflation is judged to be under control, short-term rates may decline as fears of recession replace those of inflation. Because of this uncertainty, I believe that the estimates using the long-term risk-free rate are more reliable at this time.

Of those results, the CAPM values deserve the least weight, because this method does not adjust for the empirical finding that the cost of capital is less sensitive to beta than predicted by the CAPM (which my testimony considers by using the ECAPM). Conversely, the ECAPM numbers deserve the most weight, because this method adjusts for the empirical findings.

For the electric sample, the cost of equity estimates using the long-term risk free rate, adjusted for a capital structure with 55 percent equity, range from 11.0 to 11.2 percent, and the estimates from the short-term version of the model range from 11.2 to 12.6 percent.

A review of the results in Panel A of Table No. MJV-10 (ECAPM $\alpha = 0.5$) shows that the cost of equity estimates are much less variable than for the DCF model, and range from a

low of 9.6 percent to a high of 11.4 with the except of Cleco which has an estimate of 13.2 percent for the electric sample. As noted earlier, this is due to the higher beta estimate for Cleco.

For the gas LDC sample, the cost of equity estimates using the long-term risk free rate, adjusted for a capital structure with 52 percent equity, range from 11.4 to 11.7 percent for the full sample and from 11.6 to 11.9 percent for the sub-sample. The estimates from the short-term version of the model range from 11.6 to 12.2 percent for the full sample and 11.7 to 12.4 percent for the sub-sample.

A review of the results in Panel A of Table No. MJV-21 (ECAPM $\alpha = 0.5$) also shows that the cost of equity estimates are much less variable than for the DCF model, and range from a low of 9.6 percent to a high of 11.1 with no outlier like Cleco in the electric sample.

Q59. Given the results of the two models, what is your conclusion regarding the cost of equity for Wisconsin Electric?

A59. Focusing on the middle values in Table 3 for the electric sample, the results from the long-term risk positioning model (ECAPM with $\alpha = 0.5$), the average ATWACC for the full sample is 7.7 percent, with a corresponding cost of equity estimate of 11.1 percent. I believe that Wisconsin Electric is of generally comparable business risk to the sample so the sample average ATWACC represents a good estimate of the overall cost of capital for Wisconsin Electric.

Wisconsin Electric has about $300 million of imputed debt from its purchased power contracts which would tend to increase the financial risk and therefore the cost of equity of the company relative to its adjusted regulatory capital structure with 55 percent equity. On the other hand, the sample average is pulled up by Cleco which has a noticeably higher estimated cost of capital than the rest of the electric sample companies. Based upon all of the evidence, the best point estimate for the cost of equity for Wisconsin Electric is 11 percent.

I believe that this is a conservative estimate because I have generally rounded *down* from the long-term risk-positioning results of about 11.1 percent for the sample and because of the somewhat higher overall cost of capital for the gas LDC sub-sample. In addition this estimate is about ½ percent lower than the average risk positioning results from the short-term model estimates, but it also reflects the effect on the sample of the estimates from Cleco. It is about ½ percent higher than the multistage DCF estimates. However, it is more correct to say that the estimates from the sample provide a range of values from a low of 10½ percent to a high of 11½ percent, but I feel more comfortable with an estimate in the upper half of the range. As previously noted, in estimating the cost of equity I round to the nearest ¼ percent (25 basis points) because I do not believe that cost of capital estimates can be made more precisely than that.

Q60. If the amount of imputed debt calculated by Wisconsin Electric were treated as debt in Wisconsin Electric's regulatory capital structure, how much would the return on equity change?

A60. The return on equity would increase by about 50 basis points. Without considering imputed debt, Wisconsin Electric's capital structure has 55.4 percent equity, but if imputed debt is considered, the equity percentage falls to about 51.9 percent. (See Workpaper #4 to Table No. MJV-4) This 50 basis points estimate is likely to be an upper bound on the increase in the cost of equity due to imputed debt because some of the sample companies are also likely to have imputed debt which was not considered when I calculated the sample's ATWACC.

Q61. Can the effect of imputed debt be dealt with by increasing the percentage of equity in the capital structure?

A61. Yes. One way to offset the increase in financial risk resulting from imputed debt is to increase the amount of equity in the regulatory capital structure. This approach simply involves restoring the regulatory capital structure to its percentages of debt and equity before consideration of imputed debt. In this case, considering imputed debt as real debt reduced the equity percentage from 55.4 to 51.9 percent, so restoring the equity ratio to 55.4 percent would require the addition of 3.5 percent equity to the capital structure when imputed debt is considered. When increasing equity to adjust for imputed debt, the return

on equity would remain at the requested 11.2 percent as equity is increased. As before, this is likely to be an upper bound on the amount of equity required.

Q62. Given the results of the two models, what is your conclusion regarding the cost of equity for Wisconsin Gas?

A62. Focusing on the middle values in Table 6 for the gas LDC sample, the results from the long-term risk positioning model (ECAPM with $\alpha = 0.5$), the average ATWACC for the full sample is 7.7 percent, with a corresponding cost of equity estimate of 11.5 percent for the full sample for a capital structure with 52 percent equity. The estimates are slightly higher for the sub-sample with an ATWACC of 7.8 percent and a cost of equity estimate of 11.7 percent. I believe that Wisconsin Gas is of comparable risk to the sample so the sample average ATWACC represents a good estimate of the overall cost of capital for Wisconsin Gas.

Based upon the evidence then, the best point estimate for the cost of equity for Wisconsin Gas is 11½ percent with a range of 11 to 12 percent. Just as for the electric sample, this result is about ½ percent lower than the average risk positioning results from the short-term model estimates, but it is also 1 percent higher than the multistage DCF estimates for the sub-sample. As discussed above, I do not believe that the DCF estimates are completely reliable for either industry at this time.

As with the electric sample, I believe that this is a conservative estimate of the cost of equity because it again represents a downward adjustment from the results of the more reliable sub-sample estimates which are about 20 basis points higher than the estimates for the full sample.

Q63. Do you have any final comments on the cost of capital estimates from the two samples?

A63. Yes. It is worth noting that the ATWACC estimates from the risk positioning model for both samples are very similar at about 7¾ percent although the estimates for the gas LDC sample are very slightly higher than for the electric sample. This provides some assurance that the results for both samples are reasonable because I expect the business risk of the two industries to be similar. The generally higher ATWACC estimates for the

gas LDC sample provide additional evidence of the conservative nature of the point estimate for Wisconsin Electric.

Q64. Does this conclude your testimony?

A64. Yes

APPENDIX A

RESUMÉ

MICHAEL J. VILBERT **PRINCIPAL**

Michael Vilbert is an expert in cost of capital, financial planning and valuation who has advised clients on these matters in the context of a wide variety of investment and regulatory decisions. He received his Ph.D. in Financial Economics from the Wharton School of the University of Pennsylvania, an MBA from the University of Utah, an M.S. from the Fletcher School of Law and Diplomacy, Tufts University, and a B.S. degree from the United States Air Force Academy. He joined The Brattle Group in 1994 after a career as an Air Force officer, where he served as a fighter pilot, intelligence officer, and professor of finance at the Air Force Academy.

REPRESENTATIVE CONSULTING EXPERIENCE

- In a securities fraud case, Dr. Vilbert designed and created a model to value the private placement stock of a drug store chain as if there had been full disclosure of the actual financial condition of the firm. He analyzed key financial data and security analyst's reports regarding the future of the industry in order to recreate pro forma balance sheet and income statements under a variety of scenarios designed to establish the value of the firm.

- For pharmaceutical companies rebutting price-fixing claims in antitrust litigation, Dr. Vilbert was a member of a team which prepared a comprehensive analysis of industry profitability. The analysis replicated, tested and critiqued the major recent analyses of drug costs, risks and returns. The analyses helped develop expert witness testimony to rebut allegations of excess profits.

- For an independent electric power producer, Dr. Vilbert created a model that analyzed the reasonableness of rates and costs filed by a natural gas pipeline. The model not only duplicated the pipeline's rates, but it also allowed simulation of a variety of "what if" scenarios associated with cost recovery under alternative time patterns and joint cost allocations. Results of the analysis were adopted by the intervenor group for negotiation with the pipeline.

- For the CFO of an electric utility, Dr. Vilbert developed the valuation model used to support a stranded cost estimation filing. The case involved a conflict between two utilities over the responsibility for out-of-market costs associated with a power purchase contract between them. In addition, he advised and analyzed cost recovery mechanisms

- that would allow full recovery of the stranded costs while providing a rate reduction for the company's rate payers.

- Dr. Vilbert has assisted in the preparation of testimony and the development of estimation models in numerous cost of capital cases for natural gas pipeline, water utility and electric utility clients before the Federal Energy Regulatory Commission ("FERC") and state regulatory commissions. These have spanned standard estimation techniques (e.g., Discounted Cash Flow and Risk Positioning models). He has also developed and applied more advanced models specific to the industries or lines of business in question, e.g., based on the structure and risk characteristics of cash flows, or based on multi-factor models that better characterize regulated industries.

- Dr. Vilbert has valued several large, residual oil-fired generating stations to evaluate the possible conversion to natural gas or other fuels. In these analyses, the expected pre- and post-conversion station values were computed using a range of market electricity and fuel cost conditions.

- For a major western electric utility, Dr. Vilbert helped prepare testimony that analyzed the prudence of QF contract enforcement. The testimony demonstrated that the utility had not been compensated in its allowed cost of capital for major disallowances stemming from QF contract management.

- Dr. Vilbert analyzed the economic need for a major natural gas pipeline expansion to the Midwest. This involved evaluating forecasts of natural gas use in various regions of the United States and the effect of additional supplies on the pattern of natural gas pipeline use. The analysis was used to justify the expansion before the FERC and the National Energy Board of Canada.

- For a Public Utility Commission in the Northeast, Dr. Vilbert analyzed the auction of an electric utilities purchase power agreements to determine whether the outcome of the auction was in the ratepayers' interest. The work involved the analysis of the auction procedures as well as the benefits to ratepayers of transferring risk of the PPA payments to the buyer.

- Dr. Vilbert led a team tasked to determine whether bridge tolls were "just and reasonable" for a non-profit port authority. Determination of the cost of service for the authority required estimation of the value of the authority's assets using the trended original cost methodology as well as evaluation of the operations and maintenance budgets. Investment costs, bridge traffic information and inflation indices covering a 75 year period were utilized to estimate the value of four bridges and a passenger transit line valued in excess of $1 billion.

- Dr. Vilbert helped a recently privatized railroad in Brazil develop an estimate of its revenue requirements, including a determination of the railroad's cost of capital. He also helped evaluate alternative rate structures designed to provide economic incentives to shippers as well as to the railroad for improved service. This involved the explanation

and analysis of the contribution margin of numerous shipper products, improved cost analysis and evaluation of bottlenecks in the system.

- For a utility in the Southeast, Dr. Vilbert quantified the company's stranded costs under several legislative electric restructuring scenarios. This involved the evaluation of all of the company's fossil and nuclear generating units, its contracts with Qualifying Facilities and the prudence of those QF contracts. He provided analysis concerning the impact of securitizing the company's stranded costs as a means of reducing the cost to the rate payers and several alternative designs for recovering stranded costs.

- For a recently privatized electric utility in Australia, Dr. Vilbert evaluated the proposed regulatory scheme of the Australian Competition and Consumer Commission for the company's electric transmission system. The evaluation highlighted the elements of the proposed regulation which would impose uncompensated asymmetric risks on the company and the need to either eliminate the asymmetry in risk or provide additional compensation so that the company could expect to earn its cost of capital.

- For an electric utility in the Southwest, Dr. Vilbert helped design and create a model to estimate the stranded costs of the company's portfolio of Qualifying Facilities and Power Purchase contracts. This exercise was complicated by the many variations in the provisions of the contracts that required modeling in order to capture the effect of changes in either the performance of the plants or in the estimated market price of electricity.

- Dr. Vilbert helped prepare the testimony responding to a FERC request for further comments on the appropriate return on equity for electric transmission facilities. In addition, Dr. Vilbert was a member of the team that made a presentation to the FERC staff on the expected risks of the unbundled electric transmission line of business.

- Dr. Vilbert and Mr. Frank C. Graves, also of The Brattle Group, prepared testimony evaluating an innovative Canadian stranded cost recovery procedure involving the auctioning of the output of the province's electric generation plants instead of the plants themselves. The evaluation required the analysis of the terms and conditions of the long-term contracts specifying the revenue requirements of the plants for their entire forecasted remaining economic life and required an estimate of the cost of capital for the plant owners under this new stranded cost recovery concept.

- Dr. Vilbert served as the neutral arbitrator for the valuation of a petroleum products tanker. The valuation required analysis of the Jones Act tanker market and the supply and demand balance of the available U.S. constructed tanker fleet.

TESTIMONY

Direct and rebuttal testimony before the Alberta Energy and Utilities Board on behalf of TransAlta Utilities Corporation in the matter of an application for approval of its 1999 and 2000 generation tariff, transmission tariff, and distribution revenue requirement, October 1998.

Direct testimony before the Federal Energy Regulatory Commission on behalf of Central Maine Power in Docket No. ER00-982-000, December 1999.

Direct testimony before the Alberta Energy and Utilities Board on behalf of TransAlta Utilities Corporation for approval of its 2001 transmission tariff, May 2000.

Direct testimony before the Federal Energy Regulatory Commission on behalf of Mississippi River Transmission Corporation in Docket No. RP01-292-000, March 2001.

Written evidence, rebuttal, reply and further reply before the National Energy Board in the matter of an application by TransCanada PipeLines Limited for orders pursuant to Part I and Part IV of the *National Energy Board Act*, Order AO-1-RH-4-2001, May 2001, Nov. 2001, Feb. 2002.

Written evidence before the Public Utility Board on behalf of Newfoundland & Labrador Hydro - Rate Hearings, October 2001.

Direct testimony (with Bill Lindsay) before the Federal Energy Regulatory Commission on behalf of DTE East China, LLC in Docket No. ER02-1599-000, April 2002.

Direct and rebuttal reports before the Arbitration Panel in the arbitration of stranded costs for the City of Casselberry, FL, Case No. 00-CA-1107-16-L, July 2002.

Direct reports before the Arbitration Board for Petroleum products trade in the Arbitration of the Military Sealift Command vs. Household Commercial Financial Services, fair value of sale of the Darnell, October 2002.

Direct testimony and hearing before the Arbitration Panel in the arbitration of stranded costs for the City of Winter Park, FL, In the Circuit Court of the Ninth Judicial Circuit in and for Orange County, FL, Case No. C1-01-4558-39, December 2002.

Direct testimony before the Federal Energy Regulatory Commission on behalf of Florida Power Corporation, dba Progress Energy Florida, Inc. in Docket No. SC03-___-000, March 2003.

Direct report before the Arbitration Panel in the arbitration of stranded costs for the Town of Belleair, FL, Case No. 000-6487-C1-007, April 2003.

Direct and rebuttal reports before the Alberta Energy and Utilities Board in the matter of the Alberta Energy and Utilities Board Act, R.S.A. 2000, c. A-17, and the Regulations under it; in the matter of the Gas Utilities Act, R.S.A. 2000, c. G-5, and the Regulations under it; in the matter of the Public utilities Board Act, R.S.A. 2000, c. P-45, as amended, and the Regulations

under it; and in the matter of Alberta Energy and Utilities Generic Cost of Capital Hearing, Proceeding No. 1271597, July 2003, November 2003.

Written evidence before the National Energy Board in the matter of the National Energy Board Act, R.S.C. 1985, c. N–7, as amended, (Act) and the Regulations made under it; and in the matter of an application by TransCanada PipeLines Limited for orders pursuant to Part IV of the *National Energy Board Act*, for approval of Mainline Tolls for 2004, RH-2-2004, January 2004.

Direct and rebuttal testimony before the Public Service Commission of West Virginia, on Cost of Capital for West Virginia-American Water Company, Case No 04-0373-W-42T, May 2004.

Direct and rebuttal testimony before the Federal Energy Regulatory Commission, on Energy Allocation of Debt Cost for Incremental Shipping Rates for Edison Mission Energy, Docket No. RP04-274-000, December 2004 and March 2005.

Direct testimony before the Arizona Corporation Commission, Cost of Capital for Paradise Valley Water Company, a subsidiary of Arizona-American Water Company, Docket No. WS-01303A-05, May 2005.

Written evidence before the Ontario Energy Board, Cost of Capital for Union Gas Limited, Inc., Docket No. EB-2005-0520, January 2006.

Direct and rebuttal testimony before the Pennsylvania Public Utility Commission, Return on Equity for Metropolitan Edison Company, Docket No. R-00061366 and Pennsylvania Electric Company, Docket No. R-00061367, April 2006 and August 2006.

Expert report in the United States Tax Court, Docket No. 21309-05, 34th Street Partners, DH Petersburg Investment, LLC and Mid-Atlantic Finance, Partners Other than the Tax Matters Partner, Petitioner, v. Commissioner of Internal Revenue, Respondent, July 28, 2006.

Direct and supplemental testimony before the Federal Energy Regulatory Commission, Docket No. ER06-427-003, on behalf of Mystic Development, LLC on the Cost of Capital for Mystic 8 and 9 Generating Plants Operating Under an Reliability Must Run Contract, August 2006 and September 2006.

Direct testimony before the Federal Energy Regulatory Commission, Docket No. ER07-46-000, on behalf of Northwestern Corporation on the Cost of Capital for Transmission Assets, October 2006.

Direct and rebuttal testimony before the Tennessee Regulatory Authority, Case No. 06-00290, on behalf of Tennessee American Water Company, on the Cost of Capital, November, 2006 and April 2007.

APPENDIX B

SELECTING THE GAS LDC SAMPLE AND USE OF MARKET VALUES

I. SAMPLE SELECTION AND THE SAMPLE'S CHARACTERISTICS 1

A. THE ELECTRIC UTILITIES SAMPLE 1

B. THE GAS LDC SAMPLE 3

II. MARKET VALUE CAPITAL STRUCTURE, COSTS OF DEBT & COSTS OF PREFERRED EQUITY 7

I. SAMPLE SELECTION AND THE SAMPLE'S CHARACTERISTICS

A. THE ELECTRIC UTILITIES SAMPLE

Q1. How did you select your sample of electric utilities?

A1. The goal was to create a sample of companies whose primary business is as a regulated electric utility with business risk generally similar to that of Wisconsin Electric. To construct this sample, I formed a universe of 61 companies by the electric companies under East, Central and West categories listed in *Value Line*. From this group, companies were first eliminated if their operating regions were outside of the continental USA or if they were primarily or solely engaged in generation and/or transmission. I then applied my standard selection criteria outlined earlier to remove companies that have characteristics that may bias the cost of capital estimates.

Specifically, I eliminated all companies whose S&P bond rating as reported by Bloomberg was not investment grade, i.e., less than BBB-. To guard against measurement bias caused by "thin trading," I also restricted the sample to companies with total operating revenues greater than $300 million (USD) in 2006 as reported by Bloomberg.[1] And which had no significant mergers and acquisition activity over the past five years. The screen for merger activity was primarily done by scanning each company's news history on Bloomberg and a search of company web pages. To further ensure comparability to Wisconsin Electric's operations, companies whose share of regulated assets were not estimated to be at least "Mostly Regulated", as classified by the Edison Electric Institute ("EEI"), were removed.[2]

Finally, I required that the companies have historical data available from Bloomberg for the relevant period and had no dividend cuts or restatement of financial statements in the past five years, since the latter can be signs of financial distress.

---

[1] Data was reviewed during the first week of April 2007.

[2] EEI has three classifications for electric utilities based upon the percentage of total assets that are regulated. The categories are Regulated (> 80% regulated), Mostly Regulated (50-80% regulated) and Diversified (< 50% regulated). See *EEI 2006 Financial Review*, p. 24.

A total of nine companies met all of these requirements: Cleco Corp, Consolidated Edison, Empire District Electric, Entergy Corp, MGE Energy, NSTAR, Pinnacle West Capital Corp, PPL Corp, and Southern Corp.

Q2. Please elaborate on how companies were eliminated from your sample?

A2. Eleven companies were excluded due to less than investment grade credit rating. Two companies for less than $300 million in 2006 revenues – Green Mountain Power and ITC Holding Corp., which also had less than five years of data. Of the remaining companies, 19 had excessive merger and acquisition activity ("M&A") and/or dividend cuts over the past five years. A further nine were also eliminated for dividend cuts or because they essentially own only generation or transmission assets .

Q3. Are there any issues with the remaining companies in your sample?

A3. Possibly. Although not enough merger and acquisition activity to eliminate them from the sample, three of nine companies had more activity over the past five years than the others: Cleco, Empire District Electric and Entergy. Cleco Corp.'s beta is also substantially higher at 1.30 than any of the other sample companies', which may reflect this merger activity. Two sample companies, Empire District and MGE Energy, are smaller companies compared to the others in the sample, but both have a book value of about a $1 billion making them "large" by most standards. PPL Corp and MGE Energy only fall into EEI's "Mostly Regulated" category, indicating that between 50 and 80 percent of their assets are subject to regulation. (See Table No. MJV-2 for a list of the regulated asset categorizations by EEI for each sample company.) A potential problem for the DCF estimates is that sample companies growth rate forecasts vary substantially company-to-company. For example, Cleco Corp and PPL each have a combined growth rate estimate of over 12 percent, while Consolidated Edison's combined estimate is 3.5 percent and Pinnacle West's is 2.9 percent (see column [6], Table No. MJV-5). Moreover, Bloomberg does not provide a BEst Estimate for MGE Energy, which means there is only one growth estimate for this company, and there are only two growth estimates provided for Cleco Corp. and Empire District Electric. As such, the growth rates estimates do not support the view that investors are expecting growth rates equal to the single perpetual growth rate assumed in the simple DCF model. Again, this may be

an indication that the industry conditions are not fully met for the reliable application of the DCF model. Recall that the DCF model requires stable industry conditions so that dividends, earnings, stock prices etc. are all growing at a constant rate.

Q4. How does the risk of the sample compare to the risk of Wisconsin Electric?

A4. In general, the sample appears to be of similar risk to Wisconsin Electric. Six of the nine companies are integrated utilities, and all but Empire Electric have some form of fuel-cost adjustment mechanisms covering the bulk of their operations. Three sample companies have a provider of last resort ("POLR") obligation, and they are in states that have moved to market based rates. As a result, they face a different kind of regulatory uncertainty than does Wisconsin Electric, but all sample companies face the uncertainty associated with the recent the volatility of fuel prices. Consumers have demonstrated an aversion to highly volatile energy prices, so regulatory authorities may be reluctant to allow full recovery of energy prices that are too variable.

Depending upon the recovery mechanism for the costs of providing POLR service, the risks faced by electric distribution companies with a POLR obligation may be greater than or less than those of an integrated utility. The biggest risk difference between the two is that integrated utilities own or contract for the generation capacity to meet the power needs of their customers. Although they are still exposed to changes in fuel prices as well as the construction and operating risk of owning generation, they have a natural hedge against volatile energy prices through their ownership of generation assets. POLR companies, on the other hand, are potentially exposed to changes in market prices not related to the volatility of fuel prices, because they must purchase power at market prices.

B. THE GAS LDC SAMPLE

Q5. How do you select the gas LDC sample?

A5. To select this sample, I started with the universe of publicly traded natural gas distribution utilities covered by *Value Line Investment Survey Plus*. This resulted in an initial group of 23 companies, to which I added Vectren Corporation because it is often viewed as a natural gas LDC. Vectren is involved in both gas and electric distribution

activities, but more of its regulated assets are invested in the gas distribution operations.[3] This company is also covered by *Value Line*, but is classified as an Electric Utility due to its regulated electric operations.[4] I then eliminated companies by applying additional selection criteria designed to remove companies with unique circumstances which may bias the cost of capital estimates. The final sample consists of ten gas LDCs, from which I also consider a sub-sample of four companies with the fewest reliability concerns. Table No. MJV-13 reports the estimated share of total assets for each company devoted to regulated activities in 2006.

Q6. What are the other selection criteria you applied?

A6. Companies were first eliminated if their operating regions were outside of the continental USA. I then applied my standard selection criteria to narrow the sample to those companies likely to have reliable cost of equity estimates. Specifically, I eliminated all companies whose S&P bond rating as reported by Bloomberg was not investment grade, i.e., less than BBB-. To guard against measurement bias caused by "thin trading," I also restricted the sample to companies with total operating revenues greater than $300 million (USD) in 2006 as reported by Bloomberg.[5] Companies that had a large merger during the period January 2004 to April 2007 (i.e., just over the past three years) were also generally removed from the sample, although two companies which would otherwise not survive the process were included since their primary merger activity occurred in 2004. These two companies were Atmos Energy and AGL Resources, and they were subsequently excluded from a sub-sample of *cleanest* companies I also considered as part

[3] Vectren Utility Holdings, Inc.'s 2006 10-K reveals that about 57 percent of its assets are regulated natural gas distribution assets and 37 percent are regulated electric assets. Because it has a substantial amount of regulated electric activity, I exclude it from the sub-sample of companies I consider to be the most representative of the natural gas distribution line of business and to be most free of characteristics that may bias cost of equity estimates.

[4] The 24 companies are from *Value Line Investment Survey Plus*, reviewed March 9, 2007.

[5] Data was reviewed during the first week of April 2007.

of my analysis. The screen for merger activity was primarily done by scanning each company's news history on Bloomberg and a search of company web pages.[6]

Finally, I required that the companies have historical data available from Bloomberg for the relevant period and had no dividend cuts or restatement of financial statements in the past five years, since the latter can be signs of financial distress.

Q7. Please elaborate on how companies were eliminated from your sample?

A7. Five companies were eliminated immediately because they had less than investment grade bond rating and a further four for having no bond rating. Four more companies were eliminated for excessive merger and acquisition activity ("M&A") over the past three years. For example, Keyspan Corp. was eliminated for high levels of M&A and recent dividend cuts. UGI Corp. was removed for high levels of merger activity, and because it primarily sells propane which is not regulated. Southern Union was eliminated for its unusually high levels of M&A activity. Finally, Nicor Inc. was eliminated from the sample because it restated earnings for 1999-2001 and because it settled regulatory compliance issues with the Federal Energy Regulatory Commission ("FERC") in 2003.[7]

Q8. Are there any issues with the remaining companies in your sample?

A8. Perhaps. Several companies in the sample engage in natural gas marketing activities (see Table 4 in the MJV Direct Testimony).[8] Given the turmoil of the energy trading markets, the companies' cost of capital estimates may be more volatile than those of more stable companies. Although still investment grade, Southwest Gas is at the bottom of the scale of investment grade credit ratings and has a relatively low average equity thickness over the past five years – 40.1 percent compared to over sixty percent for the remaining companies. Closer investigation shows that Southwest Gas's capital structure has been shifting rapidly towards equity over the last five years, with a level of about 50 percent

---

[6] Company web pages were searched in December 2003 for merger and acquisition activities during the 2001-2003 period, in July 2006 for merger and acquisition activities during the period 2004 through July 2006, and in December 2006 for the period August through December 2006.

[7] Nicor announced on October 29, 2002 that its earnings for 1999-2001 would be revised downwards by $15-35 million. March 4, 2003, Nicor released its restated earnings for 1999-2001 along with 2002 earnings.

[8] The percentages of regulated assets calculated for the samples are only estimates due to data reporting limitations.

over the most recent two years. These factors suggest a potential reliability problem for estimates of this company's cost of capital at this time. The Laclede Group's market cap is a bit smaller than the average of the group, but with revenues of more than $1.5 billion, it is still a large company. In 2006, Piedmont Natural Gas restated some portions of its 2003-2005 financial reports. Although this can generally lead to less reliable estimates from the equity estimation models, the restatements were not caused by fraudulent activities but were due to an accounting error in the classification of hedging amounts. This type of reclassification would not be expected to change the value of the firm and prices did not show any erratic behavior in the period surrounding the announcement of this reclassification. A potential concern for the DCF estimates is that the industry has experienced a sustained level of merger and acquisition activity over the last five years that has implication for the stability of the industry necessary for the reliable application of the DCF model. Due to the concerns with the sample, I also report the results for a sub-sample of the gas LDC sample that consists of companies with no material data issues.

Q9. Please compare the relative risk of the sample with respect to Wisconsin Gas.

A9. The sample consists of ten gas LDCs with risk characteristics generally similar to those of Wisconsin Gas. Like Wisconsin Gas, they all have fuel-cost adjustment clauses which either remove or significantly reduce their exposure to this risk. In their 10-Ks, all sample companies report that they engage in hedging activities to further reduce this risk. In addition, seven of the ten companies have weather adjustment clauses which Wisconsin Gas does not have. The sample also evidences a high degree of regulated activities, with seven of the ten companies falling into the 'Regulated' category.[9] As mentioned earlier in my direct testimony, Vectren Corp. earns a significant amount of its income from regulated electric activities despite being very active in the regulated gas LDC line of business. As such, it may be considered to be of slightly different business risk than the rest of the sample, although its S&P Business Profile in April 2006 places it in the middle of the group in terms of business risk.[10] Wisconsin Gas's S&P profile also

[9] As with the electric sample, a characterization of 'Regulated' indicates that more than 80 percent of the company's assets are regulated.

[10] Vectren was excluded from the sub-sample for this reason.

places it close to the sample group's average, though towards the less risky side of the group profiles but it does not have weather or volume adjustment clauses as do some of the sample companies.

Q10. What companies are in the sub-sample?

A10. The sub-sample consists of Laclede Group, Northwest Natural Gas, Piedmont Natural Gas and WGL Holdings. Vectren was eliminated because of its mix of both regulated natural gas and regulated electric operations. Atmos Energy and AGL Resources were eliminated because of concerns about M&A activities in 2004, and South Jersey Industries was eliminated from the sub-sample because of the accounting restatements. All remaining companies fall into the 'Regulated' category and as a group have an average S&P business profile very close to that of Wisconsin Gas.

Q11. What do you conclude from the comparison of the sample companies to Wisconsin Gas?

A11. I believe that the sample of regulated gas utility companies has business risk that is comparable on average to that of Wisconsin Gas.

II. MARKET VALUE CAPITAL STRUCTURE, COSTS OF DEBT & COSTS OF PREFERRED EQUITY

Q12. What capital structure information do you require?

A12. For reasons discussed in my written evidence and explained in detail in Appendix E, explicit evaluation of the market-value capital structures of the sample companies versus the capital structure used for rate making is vital for a correct interpretation of the market evidence. This requires estimates of the market values of common and preferred equity and debt, and the current market costs of preferred equity and debt.

Q13. How do you calculate the market-value capital structures of the sample companies?

A13. I estimate the capital structure for each company by estimating the market values of common equity, preferred equity and debt from publicly available data. The calculations

are in Panels A to I of Table No. MJV-3 for the electric sample, and Panels A to J of Table No. MJV-14 for the gas LDC sample.

The market value of equity is straightforward: the price per share times the number of shares outstanding. The market value of preferred is set equal to its book value because the portion of the capital structure financed with preferred equity is generally small. The market value of debt is estimated at the book value of debt reported by Bloomberg plus or minus the difference in the estimated fair (market) value and book value of long-term debt as reported in the companies' 10-Ks or annual reports.[11]

For purposes of assessing financial risk to common shareholders, I add an adjustment for short-term debt to the debt portion of the capital structure. This adjustment is used only for those companies whose short-term (current) liabilities exceed their short-term (current) assets. I add an amount equal to the minimum of the difference between short-term liabilities and short-term assets or the amount of short-term debt. The reason for this adjustment is to recognize that when current liabilities exceed current assets, a portion of the companies long-term assets are being financed, in effect, by short-term debt.

The market value capital structure is calculated to be consistent with the time period over which the cost of capital is estimated for the sample. The capital structure is determined over the historical period over which the relevant risk positioning parameters were determined and as of the date analysts provide forward looking growth forecasts. Therefore, Tables No. MJV-3 and MJV-14 report the market value capital structure at year end for the years ending 2002 - 2006. The output of these tables is the market equity-to-value, debt-to-value, and preferred equity-to-value ratios. The overall cost of capital calculation for the risk positioning estimates in both samples rely on the average of the market value capital structure computed for the years 2002 through 2006 as shown in Tables No. MJV-4 and MJV-15. The results in columns [1]-[3] are used in the DCF model calculations, while columns [4]-[6] are for the risk positioning models.

Q14. How do you estimate the current market cost of preferred equity?

A14. For companies with preferred equity, the cost of preferred equity for each company was set equal to the yield on an index of preferred stock as reported in the Mergent Bond Record corresponding to the S&P rating of that company's debt. The yields from Mergent were as of March 10, 2007. In general, the average amount of preferred equity in the sample companies' capital structures is very small and frequently zero. No company in either sample has more than two percent on average.[12]

Q15. How do you estimate the current market cost of debt?

A15. The market cost of debt for each company in the DCF analysis is the current yield reported by Bloomberg for a public utility company bond corresponding to the sample company's current debt rating as classified by S&P. The risk positioning analysis, on the other hand, uses the current yield of a utility bond that corresponds to the five-year average debt rating of each company so as to match consistently the horizon of information used by *Value Line* to estimate company betas. The current S&P debt ratings were obtained from Bloomberg.

Bloomberg reports that as of March 27, 2007, the average yield on A-rated Public Utility bonds was 5.85 percent, and 6.11 percent on average for BBB-rated Public Utility bonds.[13] (See Panel C of Workpaper #1 to Table No. MJV-11 for the yields on utility bonds and preferred stock by credit rating.) Calculation of the after-tax cost of debt uses the marginal tax rates provided by the companies of 39.80 percent for Wisconsin Electric and 40.048 percent for Wisconsin Gas.

---

[11] See Panels A through I in Tables No. MJV-3 and MJV-14 for details. The adjustment relies on the difference between the companies' self-reported fair value of long-term debt and the carrying value of the same line items. This information was obtained from the sample companies' annual reports.

[12] Wisconsin Electric has less than one percent preferred securities in its regulatory capital structure, while Wisconsin Gas has no preferred securities in its structure.

[13] All companies in the electric sample are either BBB, AA, or A, while in the gas LDC samples they are either BBB or A rated, except WGL Holdings which is AA-rated. The yield on AA-rated utility bonds is calculated as the yield on A-rated utility bonds minus ½ times the spread between the yield on BBB and A rated utility bonds.

APPENDIX C

RISK POSITIONING APPROACH METHODOLOGIES:

EMPIRICAL RESULTS

2. Market Risk Premium Estimation 16
C. COST OF CAPITAL ESTIMATES 16
1. Wisconsin Electric 16
2. Wisconsin Gas 17

Q1. What is the purpose of this appendix?

A1. This appendix reviews the principles behind the risk positioning methodologies, describes the estimation of the parameters used in the models, and details the cost of capital estimates obtained from these methodologies. This appendix intentionally repeats portions of my direct testimony, because I want the reader to be able to have a full discussion of the issues addressed here, rather than having to continually turn back to the corresponding section of the testimony.

I. EQUITY RISK PREMIUM METHODOLOGY

Q2. How is this section of the appendix organized?

A2. It first reviews the basic nature of the equity risk premium approach. It then discusses the individual components of the model: the benchmark risk premium, the relative risk of the company or line of business in question, the appropriate interest rate, and the combination of these elements in a particular equity risk premium model.

A. THE BASIC EQUITY RISK PREMIUM MODEL

Q3. How does the equity risk premium model work?

A3. The equity risk premium approach estimates the cost of equity as the sum of a current interest rate and a risk premium. (It therefore is sometimes also known as the "risk premium" or the "risk positioning" approach.)

This approach may sometimes be applied informally. For example, an analyst or a commission may check the spread between interest rates and what is believed to be a reasonable estimate of the cost of capital at one time, and then apply that spread to changed interest rates to get a new estimate of the cost of capital at another time.

More formal applications of equity risk premium method implement the second approach to cost of capital estimation. They use information on all securities to identify the security market line (Figure 1 in the body of the testimony) and derive the cost of capital for the individual security based on that security's relative risk. This equity risk premium

approach is widely used and underlies most of the current scholarly research on the nature, determinants and magnitude of the cost of capital.

Q4. How are "more formal applications" put into practice?

A4. The essential benchmarks that determine the security market line are the risk-free interest rate and the premium that a security of average risk commands over the risk-free rate. This premium is commonly referred to as the "market risk premium" ("MRP"), i.e., the excess of the expected return on the average common stock over the risk-free interest rate. In the equity risk premium approach the risk-free interest rate and MRP are common to all securities. A security-specific measure of relative risk (beta) is estimated separately and combined with the MRP to obtain the company-specific risk premium.

In principle, there may be more than one factor affecting the expected stock return, each with its own security-specific measure of relative risk and its own benchmark risk premium. For example, the "arbitrage pricing theory" and other "multi-factor" models have been proposed in the academic literature. These models estimate the cost of capital as the sum of a risk-free rate and several security-specific risk premiums. However, none of these alternative models has emerged in practice as "the" improvement to use instead of the original, single-factor model. I use the traditional single-factor model in this testimony.

Accordingly, the required elements in my formal equity risk premium approach are the market risk premium, an objective measure of relative risk, the risk-free rate that corresponds to the measure of the market risk premium, and a specific method to combine these elements into an estimate of the cost of capital.

B. MARKET RISK PREMIUM

Q5. Why is a risk premium necessary?

A5. Experience (e.g., the U.S. market's October Crash of 1987) demonstrates that shareholders, even well diversified shareholders, are exposed to enormous risks. By investing in stocks instead of risk-free Government bills, investors subject themselves not only to the risk of earning a return well below those they expected in any year but also to

the risk that they might lose much of their initial capital. This is why investors demand a risk premium.

I estimate two versions of the Capital Asset Pricing Model ("CAPM"). The first version measures the market risk premium as the risk premium of average risk common stocks over the long-term risk-free rate. The second version measures the risk premium relative to a short-term risk-free rate, which is the usual measure of the "market risk premium" used in capital market theories.

Q6. Please discuss some of the issues involved in selecting the appropriate MRP?

A6. To determine the cost of capital in a regulatory proceeding, the MRP should be used with a forecast of the same interest rate used to calculate the MRP (i.e., the short-term Treasury bill rate or the long-term Government rate). For example, it would be inconsistent to utilize a short-term risk-free with an estimate of the MRP derived from comparisons to long-term interest rates. In addition, the appropriate measure of the MRP should be based upon the arithmetic mean not the geometric mean return.[1] The arithmetic mean is the simple average while the geometric mean is the compound rate of return between two periods.

Q7. How do you estimate the MRP?

A7. There is presently little consensus on "best practice" for estimating the MRP, which does not mean that each approach is equally valid. For example, the latest edition of the leading graduate textbook in corporate finance, after recommending use of the arithmetic average realized excess return on the market for many years (which for awhile was noticeably over 9 percent), now reviews the current state of the research and expresses the view that the a range between 5 to 8 percent is reasonable for the U.S.[2,3]

[2] Richard A. Brealey, Stewart C. Myers, and Franklin Allen, *Principles of Corporate Finance*, McGraw-Hill, 8th edition, 2006, pp. 151-154.

[3] In past editions, the authors expressed the view that they are "most comfortable" with values toward the upper end of that range, but this language does not appear in the 8th edition. Although Professor Myers still holds this view, this language and other sections were dropped to accommodate a request to reduce the length of the text.

My written testimony considers both the historical evidence and the results of scholarly studies of the factors that affect the risk premium for average-risk stocks in order to estimate the benchmark risk premium investors currently expect. I consider the historical difference in returns between the Standard and Poor's 500 Index ("S&P 500") and the risk-free rate, recent academic literature on the MRP and the results of recent surveys to estimate the market risk premium.

Q8. Please summarize the recent literature on the MRP and the conclusions you draw from it?

A8. The new research based upon U.S. data challenges the conventional wisdom of using the arithmetic average historical excess returns to estimate the MRP. However, after reviewing the issues in the debate, I remain skeptical for several reasons that the market risk premium has declined in the U.S. as much as is claimed in some of the literature.

First, despite eye-catching claims like "equity risk premium as low as three percent,"[4] and "the death of the risk premium,"[5] not all recent research arrives at the same conclusion. In his presidential address to the American Finance Association in 2001, Professor Constantinides seeks to estimate the unconditional equity premium based on average historical stock returns.[6] (Note that this address was based upon evidence just before the major fall in market value.) He adjusts the average returns downward by the change in price-earnings ratio because he assumes no change in valuations in an unconditional state. His estimates for 1926 to 2000 and 1951 to 2000 are 8.0 percent and 6.0 percent, respectively, over the 3-month T-bill rate. In another published study in 2001, Professors Harris and Marston use the DCF method to estimate the market risk premium for the U.S. stocks.[7] Using analysts' forecasts to proxy for investors' expectation, they conclude that over the period 1982-1998 the MRP over the *long-term*

risk-free rate is 7.14 percent. As yet another example, the paper by Drs. Ibbotson and Chen (2003) adopts a supply side approach to estimate the forward looking long-term sustainable equity returns and equity risk premium based upon economic fundamentals. Their equity risk premium over the *long-term* risk-free rate is estimated to be 3.97 percent in geometric terms and 5.90 percent on an arithmetic basis. They conclude their paper by stating that their estimate of the equity risk premium is "far closer to the historical premium than being zero or negative."[8]

Second, Professor Ivo Welch surveyed a large group of financial economists in 1998 and 1999. The average of the estimated MRP was 7.1 percent in Prof. Welch's first survey and 6.7 percent in his second survey which was based on a smaller number of individuals. However, a more recent survey[9] by Prof. Welch reported only a 5.5 percent MRP.[10] In characterizing these results Prof. Welch notes that "[T]he equity premium consensus forecast of finance and economics professors seems to have dropped during the last 2 to 3 years, a period with low realized equity premia."[11]

The above quotation from Prof. Welch emphasizes the caution that must attend survey data even from knowledgeable survey participants: the outcome is likely to change quickly with changing market circumstances. Regulatory commissions should not, in my opinion, attempt to keep pace with such rapidly changing opinions.

Third, some of the evidence for negative or close to zero market risk premium simply does not make sense. Despite the relatively high valuation levels, stock returns remain much more volatile than Treasury bond returns. I am not aware of any empirical or theoretical evidence showing that investors would rationally hold equities and not expect to earn a positive risk premium for bearing the risk.

[11] *Ibid*, p. 8.

Fourth, I am unaware of a convincing theory for why the future MRP should have substantially declined. At the height of the stock market bubble in the U.S., many claimed that the only way to justify the high stock prices would be if the MRP had declined dramatically,[12] but this argument was heard less frequently after the market declined substantially from its tech bubble high. All else equal, a high valuation ratio such as price-earnings ratio implies a low required rate of return, hence a low MRP. However, there is considerable debate about whether the high level of stock prices (despite the burst of the internet bubble from its high in the summer of 2000) represents the transition to a new economy or is simply an "irrational exuberance," which cannot be sustained for the long term. If the former case is true, then the MRP may have decreased permanently. Conversely, the long-run MRP may remain the same even if expected market returns in the short-term are smaller.

Another common argument for a lower expected MRP is that the U.S. experienced very remarkable growth in the 20th century that was not anticipated at the start of the century. As a result, the average realized excess return is overestimated meaning the standard method of estimating the MRP would be biased upward. However, one recent study by Profs. Jorion and Goetzmann finds, under some simplifying assumptions, that the so-called "survivorship bias" is only 29 basis points.[13] Furthermore, "[I]f investors have overestimated the equity premium over the second half of the last century, Constantinides (2002) argues that 'we now have a bigger puzzle on our hands' Why have investors systematically biased their estimates over such a long horizon?"[14]

---

[12] See Robert D. Arnott and Peter L. Bernstein, "What Risk Premium is 'Normal'?," *Financial Analysts Journal* 58:64-85, for an example.

[13] Jorion, P., and W. Goetzmann (1999), "Global Stock Markets in the Twentieth Century," *Journal of Finance* 54:953-980. Dimson, Marsh, and Staunton (2003) make a similar point when they comment on the equity risk premia for 16 countries based on returns between 1900 and 2001: "While the United States and the United Kingdom have indeed performed well, compared to other markets there is no indication that they are hugely out of line." p.4.

[14] Mehra, R., and E.C. Prescott (2003), "The Equity Premium in Retrospect," in *Handbook of the Economics of Finance*, Edited by G.M. Constantinides, M. Harris and R. Stulz, Elsevier B.V, p. 926

To sum up the above, I cite two passages from Profs. Mehra and Prescott's review of the theoretical literature on equity premium puzzle:[15]

> Even if the conditional equity premium given current market conditions is small, and there appears to be general consensus that it is, this in itself does not imply that it was obvious either that the historical premium was too high or that the equity premium has diminished.
>
> In the absence of this [knowledge of the future], and based on what we currently know, we can make the following claim: over the long horizon the equity premium is likely to be similar to what it has been in the past and the returns to investment in equity will continue to substantially dominate that in T-bills for investors with a long planning horizon.

Q9. Is there other scholarly support for the conclusion?

A9. Yes. Another line of research was pursued by Steven N. Kaplan and Richard S. Ruback. They estimate the market risk premium in their article, "The Valuation of Cash Flow Forecasts: An Empirical Analysis."[16] Professors Kaplan and Ruback compare published cash flow forecasts for management buyouts and leveraged recapitalization over the 1983 to 1989 period against the actual market values that resulted from these transactions. One of their results is an estimate of the market risk premium over the long-term Treasury bond yield that is based on careful analysis of actual major investment decisions, not realized market returns. Their median estimate is 7.78 percent and their mean estimate is 7.97 percent.[17] This is considerably higher than my estimate of 6.5 percent. Even if the maturity premium of Treasury bonds over Treasury bills were only 1 percent, well below the best estimate of 1.5 percent the resulting estimate of the market risk premium over Treasury bills is higher than my estimate of 8.0 percent.

[16] *Journal of Finance*, 50, September 1995, pp. 1059-1093.

[17] *Ibid*, p. 1082.

Q10. In addition to the scholarly articles and survey evidence you discussed in Section I.B of your Direct Testimony, what other evidence do you consider to estimate the MRP?

A10. I also consider the long-run realized equity premiums reported in Morningstar *SBBI Valuation Edition 2007 Yearbook*. The data provided cover the period 1926 through 2006. The results are discussed below.

Q11. What is the "long-run realized risk premium" in the U.S.?

A11. From 1926 to 2006, the full period reported, Morningstar's data show that the average premium of stocks over Treasury bills is 8.6 percent. I also examine the "post-War" period. The risk premium for 1947-2006 is 8.4 percent.[18] (I exclude 1946 because its economic statistics are heavily influenced by the War years; e.g., the end of price controls yielded an inflation rate of 18 percent. It is not really a "post-War" year, from an economic viewpoint.) These averages often change slightly when another year of data is added to the Ibbotson series. The average premium of stocks over the income returns on long-term Government bonds is 7.1 percent for the 1926 to 2006 period and 7.1 for the 1947 to 2006 period.

Recently there has been a great deal of academic research on the MRP. This research has put practitioners in a dilemma: there is nothing close to a consensus about how the MRP should be estimated, but a general agreement in the academic community seems to be emerging that the old approach of using the average realized return over long periods gives too high an answer.

Q12. What is your conclusion regarding the MRP?

A12. Estimation of the MRP remains controversial. There is no consensus on its value or even how to estimate it. Given a careful review of all of the information, I estimate the risk premium for average risk stocks to be 8.0 percent over Treasury bills and 6.5 percent over long-term Government bonds.

[18] Morningstar, *SBBI Valuation Edition 2007 Yearbook*, Appendix A.

C. RELATIVE RISK

Q13. How do you measure relative risk?

A13. The risk measure I examine is the "beta" of the stocks in question. Beta is a measure of the "systematic" risk of a stock — the extent to which a stock's value fluctuates more or less than average when the market fluctuates. It is the most commonly used measure of risk in capital market theories.

Q14. Please explain beta in more detail.

A14. The basic idea behind beta is that risks that cannot be diversified away in large portfolios matter more than those that can be eliminated by diversification. Beta is a measure of the risks that *cannot* be eliminated by diversification.

Diversification is a vital concept in the study of risk and return. (Harry Markowitz won a Nobel Prize for work showing just how important it was.) Over the long run, the rate of return on the stock market has a very high standard deviation, on the order of 15 - 20 percent per year. But many individual stocks have much higher standard deviations than this. The stock market's standard deviation is "only" about 15 - 20 percent because when stocks are combined into portfolios, some of the risk of individual stocks is eliminated by diversification. Some stocks go up when others go down, and the average portfolio return — positive or negative — is usually less extreme than that of individual stocks within it.

In the limiting case, if the returns on individual stocks were completely uncorrelated with one another, the formation of a large portfolio of such stocks would eliminate risk entirely. That is, the market's long-run standard deviation would be not 15-20 percent per year, but virtually zero.

The fact that the market's actual annual standard deviation is so large means that, in practice, the returns on stocks are correlated with one another, and to a material degree. The reason is that many factors that make a particular stock go up or down also affect other stocks. Examples include the state of the economy, the balance of trade, and inflation. Thus some risk is "non-diversifiable". Single-factor equity risk premium models derive conditions in which all of these factors can be considered simultaneously,

through their impact on the market portfolio. Other models derive somewhat less restrictive conditions under which several of them might be individually relevant.

Again, the basic idea behind all of these models is that risks that cannot be diversified away in large portfolios matter more than those that can be eliminated by diversification, because there are a large number of large portfolios whose managers actively seek the best risk-reward tradeoffs available. Of course, undiversified investors would like to get a premium for bearing diversifiable risk, but they cannot.

Q15. Why not?

A15. Well-diversified investors compete away any premium rates of return for diversifiable risk. Suppose a stock were priced especially low because it had especially high diversifiable risk. Then it would seem to be a bargain to well diversified investors. For example, suppose an industry is subject to active competition, so there is a large risk of loss of market share. Investors who held a portfolio of all companies in the industry would be immune to this risk, because the loss on one company's stock would be offset by a gain on another's stock. (Of course, the competition might make the whole industry more vulnerable to the business cycle, but the issue here is the diversifiable risk of shifts in market share among firms.)

If the shares were priced especially low because of the risk of a shift in market shares, investors who could hold shares of the whole industry would snap them up. Their buying would drive up the stocks' prices until the premium rates of return for diversifiable risk were eliminated. Since all investors pay the same price, even those who are not diversified can expect no premium for bearing diversifiable risk.

Of course, substantial non–diversifiable risk remains, as the October Crash of 1987 demonstrates. Even an investor who held a portfolio of all traded stocks could not diversify against that type of risk. Sensitivity to such market–wide movements is what beta measures. That type of sensitivity, whether considered in a single- or multi-factor model, determines the risk premium in the cost of equity.

Q16. What does a particular value of beta signify?

A16. By definition, a stock with a beta equal to 1.0 has average non-diversifiable risk: it goes up or down by 10 percent on average when the market goes up or down by 10 percent. Stocks with betas above 1.0 exaggerate the swings in the market: stocks with betas of 2.0 tend to fall 20 percent when the market falls 10 percent, for example. Stocks with betas below 1.0 are less volatile than the market. A stock with a beta of 0.5 will tend to rise 5 percent when the market rises 10 percent.

Q17. How is beta measured?

A17. The usual approach to calculating beta is a statistical comparison of the sensitivity of a stock's (or a portfolio's) return to the market's return. Many investment services report betas, including Merrill Lynch's quarterly Security Risk Evaluation, Bloomberg and the *Value Line Investment Survey*. Betas are not always calculated the same way, and therefore must be used with a degree of caution, but the basic point that a high beta indicates a risky stock has long been widely accepted by both financial theorists and investment professionals.

Q18. Are there circumstances when the "usual approach" should not be used?

A18. There are at least two cases where the standard estimate of beta should be viewed skeptically.

First, companies in serious financial distress seem to "decouple" from their normal sensitivity to the stock market. The stock prices of financially distressed companies tend to change based more on individual news about their particular circumstances than upon overall market movements. Thus, a risky stock could have a low estimated beta if the company was in financial distress. Other circumstances that may cause a company's stock to decouple include an industry restructuring or major changes in a company's supply or output markets.

Second, similar circumstances seem to arise for companies "in play" during a merger or acquisition. Once again, the individual information about the progress of the proposed takeover is so much more important for that stock than day-to-day market fluctuations that, in practice, beta estimates for such companies seem to be too low.

Q19. How reliable is beta as a risk measure?

A19. Scholarly studies have long confirmed the importance of beta for a stock's required rate of return. It is widely regarded as the best single risk measure available. The merits of beta seemed to have been challenged by widely publicized work by Professors Eugene F. Fama and Kenneth R. French.[19] However, despite the early press reports of their work as signifying that "beta is dead," it turns out that beta is still a potentially important explanatory factor (albeit one of several) in their work. Thus, beta remains alive and well as the best single measure of relative risk.

D. INTEREST RATE FORECAST

Q20. What interest rates do your procedures require?

A20. Modern capital market theories of risk and return use the short-term risk-free rate of return as the starting benchmark. My measures of the MRP incorporate this approach, since they represent the excess of the expected return on the market over the 30-day U.S. Treasury bill rate and over the long-term U.S. Government bond rate. Accordingly, implementation of my procedures requires use of a forecast of the 30-day Treasury bill rate and the long-term Government bond rate.

E. COST OF CAPITAL MODELS

Q21. How do you combine the above components into an estimate of the cost of capital?

A21. By far the most widely used approach to estimation of the cost of capital is the "Capital Asset Pricing Model," and I do calculate CAPM estimates. However, the CAPM is only one equity risk premium approach technique, and I also use another.

Q22. Please start with the CAPM, by describing the model.

A22. As noted above, the modern models of capital market equilibrium express the cost of equity as the sum of a risk-free rate and a risk premium. The CAPM is the longest-standing and most widely used of these theories. The CAPM states that the cost of

[19] See for example, "The Capital Asset Pricing Model: Theory and Evidence", Eugene F. Fama and Kenneth R. French, *Journal of Economic Perspectives*, Volume 18, Summer 2004, pp. 25-46.

capital for investment I (e.g., a particular common stock) is given by the following equation:

$$k_s = r_f + \beta_s \times MRP \quad \textbf{(C-1)}$$

where k_s is the cost of capital for investment s; r_f is the risk-free rate, β_s is the beta risk measure for the investment s; and MRP is the market risk premium.

The CAPM relies on the empirical fact that investors price risky securities to offer a higher expected rate of return than safe securities do. It says that the security market line starts at the risk-free interest rate (that is, that the return on a zero-risk security, the y-axis intercept in Figure 1 in the body of my testimony, equals the risk-free interest rate). Further, it says that the risk premium over the risk-free rate equals the product of beta and the risk premium on a value-weighted portfolio of all investments, which by definition has average risk.

Q23. What other equity risk premium approach model do you use?

A23. Empirical research has long shown that the CAPM tends to overstate the actual sensitivity of the cost of capital to beta: low-beta stocks tend to have higher risk premia than predicted by the CAPM and high-beta stocks tend to have lower risk premia than predicted. A number of variations on the original CAPM theory have been proposed to explain this finding. The difference between the CAPM and the type of relationship identified in the empirical studies is depicted in Figure MJV-C1.

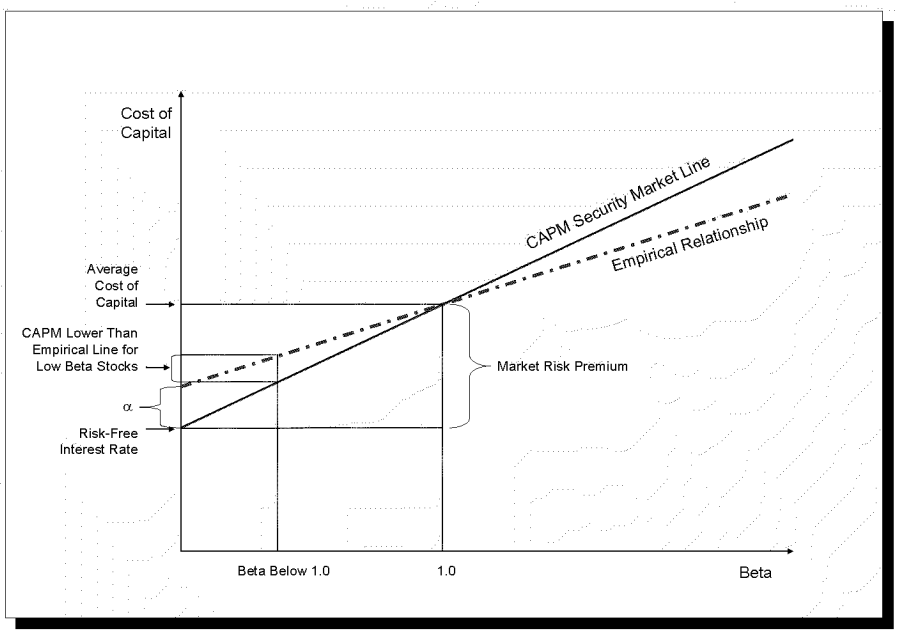

Figure MJV-C1: The Empirical Security Market Line

The second model makes use of these empirical findings. It estimates the cost of capital with the equation, where α is the "alpha" of the risk-return line, a constant,

$$k_s = r_f + \alpha + \beta_s \times (MRP - \alpha) \qquad \textbf{(C-2)}$$

and the other symbols are defined as above. I label this model the Empirical Capital Asset Pricing Model, or "ECAPM." For the short-term risk-free rate models, I set alpha equal to 1, 2, and 3 percent which are values somewhat lower than that estimated empirically. For low-beta stocks such as regulated utilities, the use of a lower value for alpha leads to a lower estimate of the cost of capital. For the long-term risk-free rate models, I set alpha equal to both 0.5 percent and 1.5 percent, but I rely more heavily on the 0.5 percent results. The use of a long-term risk-free rate incorporates some of the desired effect of using the ECAPM. That is, the long-term risk-free rate version of the Security Market Line has a higher intercept and a flatter slope than the short-term risk-free version which has been tested. Thus, it is likely that I do not need to make the same degree adjustment when I use the long-term risk-free rate. A summary of the empirical evidence on the magnitude of alpha is provided in Table No. MJV-C1 below.

II. EMPIRICAL EQUITY RISK PREMIUM RESULTS

Q24. How is this part of the appendix organized?

A24. This section presents the full details of my equity risk premium approach analyses, which are summarized in the body of my testimony. This section discusses the sample selection process, calculation of the market value capital structures, and the forecasts of the short-term and the long-term risk-free interest rates. Next, it addresses the beta estimates, and the estimates of the MRP I use in the models. Finally, it reports the CAPM and ECAPM results for the samples' costs of equity, and then describes the results of adjusting for differences between the benchmark samples and each of the Applicants at their regulated capital structures.

A. RISK-FREE INTEREST RATE FORECAST

Q25. How do you obtain the forecasts of the risk-free interest rates over the period the utility rates set here are to be in effect?

A25. I obtain these forecast rates using data provided by Bloomberg. In particular, I use their reported government debt yields from the "constant maturity series". This information is displayed in Panels A and B of both Tables No. MJV-9.

Q26. What values do you use for the short-term and long-term risk-free interest rates?

A26. I use a value of 3.8 percent for the short-term risk-free interest rate and a value of 4.9 percent for the long-term risk-free interest rate as the benchmark interest rates in the equity risk premium analyses for both samples. These forecasts are constructed by using historical yield curve data to find the long-run average implied term premia on government securities, and combining these with recent yield curve data. Details of their calculation can be found in the Workpapers to Table No. MJV-9.

B. BETAS AND THE MARKET RISK PREMIUM

1. Beta Estimation Procedures

Q27. How do you estimate beta for each of the benchmark samples?

A27. I use the beta estimates reported in the *Value Line* for both the electric and the gas LDC sample companies. The current *Value Line* beta estimates range from 0.70 to 1.30 for the electric sample (See Workpaper #1 to Table No. MJV-10), and 0.70 to 0.95 for the gas LDC sample (See Workpaper #1 to Table No. MJV-20).

2. Market Risk Premium Estimation

Q28. Given all of the evidence, what MRP do you use in your analysis?

A28. It is clear that market return information is volatile and difficult to interpret, but based on the collective evidence, the MRP I use for the short-term risk-free rate is 8 percent and for the long-term risk-free rate is 6.5 percent.

C. COST OF CAPITAL ESTIMATES

1. Wisconsin Electric

Q29. Based on these data, what are the values you calculate for the overall cost of capital and the corresponding cost of equity for the electric sample?

A29. Panels A and B of Table No. MJV-10 present the cost of equity results using the equity risk positioning methods. Panel A uses the long-term risk-free rate forecast while Panel B uses the short-term risk-free rate forecast. These returns on equity are replicated and the overall cost of capital for the various equity risk positioning methods are reported in Table No. MJV-11. Panels A through C utilize the long-term risk-free rate while Panels D through G use the short-term risk free rate. Panel A reports the cost of capital estimates using the CAPM results for the long-term risk-free rate, while Panels B and C report these estimates for the ECAPM cost of equity results using ECAPM parameters of 0.5 and 1.5 percent, respectively. Panel D reports the CAPM estimates using the short-term risk free rate, while Panels E, F and G report ECAPM results using ECAPM

parameters of 1, 2 and 3 respectively. In each panel, column [8] reports the overall cost of capital for each company. The last row of each panel reports the sample average.

Q30. What does the electric sample market data imply about the sample's cost of equity at Wisconsin Electric's proposed 55.38 percent equity ratio?

A30. The sample average ATWACC from each panel of Table No. MJV-11 is reproduced in column [1] of Table No. MJV-12, which then reports the cost of equity for each of the risk positioning methods that is consistent with the sample information and the capital structure of Wisconsin Electric. Panel A of Table No. MJV-12 reports the results for all sample companies. The sample average ATWACCs and corresponding costs of equity at a 55.38 percent equity ratio are also displayed in Table 3 of my testimony.

I discuss the implications of the equity risk positioning results for the electric sample in the main body of my testimony.

2. Wisconsin Gas

Q31. Based on these data, what are the values you calculate for the overall cost of capital and the corresponding cost of equity for the gas LDC sample?

A31. Panels A and B of Table No. MJV-20 present the cost of equity results using the equity risk positioning methods. Panel A uses the long-term risk-free rate forecast while Panel B uses the short-term risk-free rate forecast. These returns on equity are replicated and the overall cost of capital for the various equity risk positioning methods are reported in Table No. MJV-21. Panels A through C utilize the long-term risk-free rate while Panels D through G use the short-term risk free rate. Panel A reports the cost of capital estimates using the CAPM results for the long-term risk-free rate, while Panels B and C report these estimates for the ECAPM cost of equity results using ECAPM parameters of 0.5 and 1.5 percent, respectively. Panel D reports the CAPM estimates using the short-term risk free rate, while Panels E, F and G report ECAPM results using ECAPM parameters of 1, 2 and 3 respectively. In each panel, column [8] reports the overall cost of capital for each company. The last two rows of each panel report the sample and sub-sample averages. The first is for all companies in the gas LDC sample and the second is for the sub-sample of companies which exhibit the fewest reliability issues and which, in

my opinion, are most representative of the business risk of Wisconsin Gas's utility operations.

Q32. What does the gas LDC sample market data imply about the sample's cost of equity at Wisconsin Gas's proposed 52.16 percent equity ratio?

A32. The sample average ATWACC from each panel of Table No. MJV-21 is reproduced in column [1] of Table No. MJV-22, which then reports the cost of equity for each of the risk positioning methods that is consistent with the sample information and the capital structure of Wisconsin Gas. Panel A of Table No. MJV-22 reports the results for all sample companies. Panel B of the table summarizes the results for the sub-sample of companies that have a larger percentage of revenues from regulated activities and fewer data problems. The results for the sub-sample are generally slightly higher than for the full sample. The sample average ATWACCs and corresponding costs of equity at a 52 .16 percent equity ratio are also displayed in Table 6 of my testimony.

I discuss the implications of the equity risk positioning results for gas LDC sample in the main body of my testimony.

Table MJV-C1

EMPIRICAL EVIDENCE ON THE ALPHA FACTOR IN ECAPM*		
AUTHOR	RANGE OF ALPHA	PERIOD RELIED UPON
Black (1993)[1]	1% for betas 0 to 0.80	1931-1991
Black, Jensen and Scholes (1972)[2]	4.31%	1931-1965
Fama and McBeth (1972)	5.76%	1935-1968
Fama and French (1992)[3]	7.32%	1941-1990
Litzenberger and Ramaswamy (1979)[4]	5.32%	1936-1977
Litzenberger, Ramaswamy and Sosin (1980)	1.63% to 3.91%	1926-1978
Pettengill, Sundaram and Mathur (1995)[5]	4.6%	1936-1990

*The figures reported in this table are for the longest estimation period available and, when applicable, use the authors' recommended estimation technique. Many of the articles cited also estimate alpha for sub-periods and those alphas may vary.

[1]Black estimates alpha in a one step procedure rather than in an un-biased two-step procedure.

[2]Estimate a negative alpha for the subperiod 1931-39 which contain the depression years 1931-33 and 1937-39.

[3]Calculated using Ibbotson's data for the 30-day treasury yield.

[4]Relies on Lizenberger and Ramaswamy's before-tax estimation results. Comparable after-tax alpha estimate is 4.4%.

[5]Pettengill, Sundaram and Mathur rely on total returns for the period 1936 through 1990 and use 90-day treasuries. The 4.6% figure is calculated using auction averages 90-day treasuries back to 1941 as no other series were found this far back.

APPENDIX D

DISCOUNTED CASH FLOW METHODOLOGY:

DETAILED PRINCIPLES AND RESULTS

I. DISCOUNTED CASH FLOW METHODOLOGY PRINCIPLES 1

A. SIMPLE AND MULTI-STAGE DISCOUNTED CASH FLOW MODELS 1

B. CONCLUSIONS ABOUT DCF 7

II. EMPIRICAL DCF RESULTS 7

A. PRELIMINARY MATTERS 8

B. GROWTH RATES 8

C. DIVIDEND AND PRICE INPUTS 11

D. COMPANY-SPECIFIC DCF COST OF CAPITAL ESTIMATES 12

Q1. What is the purpose of this appendix?

A1. This appendix reviews the principles behind the discounted cash flow or "DCF" methodology and the details of the cost of capital estimates obtained from this methodology.

I. DISCOUNTED CASH FLOW METHODOLOGY PRINCIPLES

Q2. How is this section of the appendix organized?

A2. The first part discusses the general principles that underlie the DCF approach. The second portion describes the strengths and weaknesses of the DCF model and why it is generally less reliable for estimating the cost of capital for the sample companies at the present time than the risk positioning method discussed in Appendix C.

A. SIMPLE AND MULTI-STAGE DISCOUNTED CASH FLOW MODELS

Q3. Please summarize the DCF model.

A3. The DCF model takes the first approach to cost of capital estimation discussed with Figure 1 in Section II-A of my direct testimony. That is, it attempts to measure the cost of equity in one step. The method assumes that the market price of a stock is equal to the present value of the dividends that its owners expect to receive. The method also assumes that this present value can be calculated by the standard formula for the present value of a cash flow stream:

$$P = \frac{D_1}{(1+k)} + \frac{D_2}{(1+k)^2} + \frac{D_3}{(1+k)^3} + \cdots + \frac{D_T}{(1+k)^T} \qquad \textbf{(D-1)}$$

where "P" is the market price of the stock; "D_i" is the dividend cash flow expected at the end of period i; "k" is the cost of capital; and "T" is the last period in which a dividend cash flow is to be received. The formula just says that the stock price is equal to the sum of the expected future dividends, each discounted for the time and risk between now and the time the dividend is expected to be received.

Most DCF applications go even further, and make very strong (*i.e.*, unrealistic) assumptions that yield a simplification of the standard formula, which then can be rearranged to estimate the cost of capital. Specifically, if investors expect a dividend stream that will grow forever at a steady rate, the market price of the stock will be given by a very simple formula,

$$P = \frac{D_1}{(k-g)} \qquad \textbf{(D-2)}$$

where "D_1" is the dividend expected at the end of the first period, "g" is the perpetual growth rate, and "P" and "k" are the market price and the cost of capital, as before. Equation D-2 is a simplified version of Equation D-1 that can be solved to yield the well known "DCF formula" for the cost of capital:

$$\begin{aligned} k &= \frac{D_1}{P} + g \\ &= \frac{D_0 \times (1+g)}{P} + g \end{aligned} \qquad \textbf{(D-3)}$$

where "D_0" is the current dividend, which investors expect to increase at rate g by the end of the next period, and the other symbols are defined as before. Equation D-3 says that if Equation D-2 holds, the cost of capital equals the expected dividend yield plus the (perpetual) expected future growth rate of dividends. I refer to this as the simple DCF model. Of course, the "simple" model is simple because it relies on very strong (*i.e.*, very unrealistic) assumptions.

Q4. Are there other versions of the DCF models besides the "simple" one?

A4. Yes. If Equation D-2 does not hold, sometimes other variations of the general present value formula, Equation D-1, can be used to solve for k in ways that differ from Equation D-3. For example, if there is reason to believe that investors do *not* expect a steady growth rate forever, but rather have different growth rate forecasts in the near term (e.g., over the next five or ten years), these forecasts can be used to specify the early dividends in Equation D-1. Once the near-term dividends are specified, Equation D-2 can be used to specify the share price value at the end of the near-term (e.g., at the end of five or ten

years), and the resulting cash flow stream can be solved for the cost of capital using Equation D-1.

More formally, the "multi-stage" DCF approach solves the following equation for k:

$$P = \frac{D_1}{(1+k)} + \frac{D_2}{(1+k)^2} + \frac{D_3}{(1+k)^3} + \cdots + \frac{D_T + P_{TERM}}{(1+k)^T} \quad \textbf{(D-4)}$$

The terminal price, P_{TERM} is estimated as

$$P_{TERM} = \frac{D_{T+1}}{(k - g_{LR})} \quad \textbf{(D-5)}$$

where T is the last of the periods in which a near term dividend forecast is made and g_{LR} is the long-run growth rate. Thus, Equation D-4 defers adoption of the very strong perpetual growth assumptions that underlie Equation D-2 — and hence the simple DCF formula, Equation D-3 — for as long as possible, and instead relies on near term knowledge to improve the estimate of k. I examine both simple and multi-stage DCF results below.

Q5. What are the merits of the DCF model?

A5. The DCF approach is conceptually sound if its assumptions are met but can run into difficulty in practice because those assumptions are so strong, and hence so unlikely to correspond to reality. Two conditions are well-known to be necessary for the DCF approach to yield a reliable estimate of the cost of capital: the variant of the present value formula, Equation D-1, that is used must actually match the variations in investor expectations for the dividend growth path; and the growth rate(s) used in that formula must match current investor expectations. Less frequently noted conditions may also create problems.

The DCF model assumes that investors expect the cost of capital to be the same in all future years. Investors may not expect the cost of capital to be the same, which can bias the DCF estimate of the cost of capital in either direction.

The DCF model only works for companies for which the standard present value formula works. The standard formula does *not* work for companies that operate in industries or markets options (*e.g.*, puts and calls on common stocks), and so it will not work for companies whose stocks behave as options do. Option-pricing effects will be important for companies in financial distress, for example, which implies the DCF model will *understate* their cost of capital, all else equal.

In recent years even the most basic DCF assumption, that the market price of a stock in the absence of growth options is given by the standard present value formula (*i.e.*, by Equation D-1 above), has been called into question by a literature on market volatility.[1] In any case, it is still too early to throw out the standard formula, if for no other reasons than that the evidence is still controversial and no one has offered a good replacement. But the evidence suggests that it must be viewed with more caution than financial analysts have traditionally applied. Simple models of stock prices may not be consistent with the available evidence on stock market volatility.

Q6. Normally DCF debates center on the right growth rate. What principles underlie that choice?

A6. Finding the right growth rate(s) is indeed the usual "hard part" of a DCF application. The original approach to estimation of g relied on average historical growth rates in observable variables, such as dividends or earnings, or on the "sustainable growth" approach, which estimates g as the average book rate of return times the fraction of earnings retained within the firm. But it is highly unlikely that historical averages over periods with widely varying rates of inflation, interest rates and costs of capital, such as in the relatively recent past, will equal current growth rate expectations.

---

[1] See for example, Robert J. Shiller (1981), "Do Stock Prices Move Too Much to be Justified by Subsequent Changes in Dividends?," *The American Economic Review*, Vol. 71, No. 3, pp. 421-436. John Y. Campbell and Robert J. Shiller (1988), "The Dividend-Price Ratio and Expectations of Future Dividends and Discount Factors," *The Review of Financial Studies*, Vol. 1, No. 3, pp. 195-228. Lucy F. Ackert and Brian F. Smith (1993), "Stock Price Volatility, Ordinary Dividends, and Other Cash Flows to Shareholders," *Journal of Finance*, Vol. 48, No. 1, pp. 1147-1160. Eugene F. Fama and Kenneth R. French (2001), "Disappearing Dividends: Changing Firm Characteristics or Lower Propensity to Pay?," *Journal of Financial Economics*, Vol. 60, pp. 3-43. Borja Larrain and Motohiro Yogo (2005), "Does Firm Value Move Too Much to be Justified by Subsequent Changes in Cash Flow?," Federal Reserve Bank of Boston, *Working Paper*, No. 05-18.

A better approach is to use the growth rates currently expected by investment analysts, if an adequate sample of such rates is available. If this approach is feasible and if the person estimating the cost of capital is able to select the appropriate version of the DCF formula, the DCF method should yield a reasonable estimate of the cost of capital for companies not in financial distress and without material option-pricing effects (always subject to recent concerns about the applicability of the basic present value formula to stock prices as well as issues of optimism bias). However, for the DCF approach to work, the basic stable-growth assumption must become reasonable and the underlying stable-growth rate must become determinable *within the period for which forecasts are available*.

Q7. What is the so called "optimism bias" in the earnings growth rate forecasts of security analysts and what is its effect on the DCF analysis?

A7. Optimism bias is related to the observed tendency for analysts to forecast earnings growth rates that are higher than are actually achieved. This tendency to over estimate growth rates is perhaps related to incentives faced by analysts that provide rewards not strictly based upon the accuracy of the forecasts. To the extent optimism bias is present in the analysts' earnings forecasts, the cost of capital estimates from the DCF model would be too high.

Q8. Does optimism bias mean that the DCF estimates are completely unreliable?

A8. No. The effect of optimism bias is least likely to affect DCF estimates for large, rate regulated companies in relatively stable segments of an industry. Furthermore, the magnitude of the optimism bias (if any) for regulated companies is not clear. This issue is addressed in a paper by Chan, Karceski, and Lakonishok (2003)[2] who sort companies on the basis of the size of the I/B/E/S forecasts to test the level of optimism bias. Utilities constitute 25 percent of the companies in lowest quintile, and by one measure the level of optimism bias is 4 percent. However, the 4 percent figure does not represent the complete characterization of the results in the paper. Table IX of the paper shows that the median I/B/E/S forecast for the first (lowest) quintile averages 6.0 percent. The

[2] L. K.C. Chan, J. Karceski, and J. Lakonishok, 2003, "The Level and Persistence of Growth Rates," *Journal of Finance* 58(2):643-684.

realized "Income before Extraordinary Items" is 2.0 percent (implying a four percent upward bias in I/B/E/S forecasts), but the "Portfolio Income before Extraordinary Items" is 8.0 percent (implying a two percent downward bias in I/B/E/S forecasts).

The difference between the "Income before Extraordinary Items" and "Portfolio Income before Extraordinary Items" is whether individual firms or a portfolio are used in estimating the realized returns. The first is a simple average of all firms in the quintile while the second is a market value weighted-average. Although both measures of bias have their own drawbacks according to the authors,[3] the Portfolio Income measure gives more weight to the larger firms in the quintile such as regulated utilities. In addition, the paper demonstrates that "analysts' forecasts as well as investors' valuations reflect a wide-spread belief in the investment community that many firms can achieve streaks of high growth in earnings."[4] Therefore, it is not clear how severe the problem of optimism bias may be for regulated utilities or even whether there is a problem at all.

Finally, the two-stage DCF model also adjusts for any over optimistic (or pessimistic) growth rate forecasts by substituting the long-term GDP growth rate for the 5-year growth rate forecasts of the analysts in the years after year 5.

Q9. What about the reforms by the National Associate of Security Dealers (NASD) that were designed to reduce the conflicts of interest and pressures brought against security analysts? Have those reforms been generally successful?

A9. Yes. The conclusion from the Joint Report by NASD and the New York Stock Exchange ("NYSE") on the reforms states

> … the SRO Rules have been effective in helping restore integrity to research by minimizing the influences of investment banking and promoting transparency of other potential conflicts of interest. Evidence also suggests that investors are benefiting from more balanced and accurate research to aid their investment decisions.[5]

---

[3] Chan, Karceski, and Lakonishok, *op. cit.*, p. 675.

[4] Chan, Karceski, and Lakonishok, *op. cit.*, p. 663.

[5] Joint Report by NASD and NYSE on the Operation and Effectiveness of the Research Analyst Conflict of Interest Rules, December 2005, p. 44.

The report does note additional reforms are advisable, but the situation is far different today than during the height of the tech bubble when analyst objectivity was clearly suspect.

B. CONCLUSIONS ABOUT DCF

Q10. Please sum up the implications of this part of the appendix.

A10. The unavoidable questions about the DCF model's strong assumptions — whether the basic present value formula works for stocks, whether option pricing effects are important for the company, whether the right variant of the basic formula has been found, and whether the true growth rate expectations have been identified — cause me to view the DCF method as *inherently* less reliable than equity risk premium approach, the other approach I use. However, because the DCF method has been widely used in the past and in other forums when the industry's economic conditions were different from today's, I submit DCF evidence in this case. DCF estimates also serve as a check on the values provided by the risk positioning approach methods.

II. EMPIRICAL DCF RESULTS

Q11. How is this part of the appendix organized?

A11. This section presents the details of my DCF analyses for each sample, which are summarized in my written evidence. The first part describes some preliminary matters, such as the calculation of market value capital structures of the sample companies and the determination of the growth rates. It then turns to the details of the DCF estimates themselves.

In particular, implementation of the simple DCF models described above requires an estimate of the current price, the dividend, and near-term and long-run growth rate forecasts. The simple DCF model relies only on a single growth rate forecast, while the multistage DCF model employs both near-term individual company forecasts and long-run GDP growth rate forecasts. The remaining parts of this section describe each of these inputs in turn.

A. PRELIMINARY MATTERS

Q12. In Appendix C you discuss estimating cost of capital and implied cost of equity using the risk positioning methodology. What, if anything, is different when you use the DCF method?

A12. First, the timing of the market value capital structure calculations is different in the DCF method than in the equity risk premium method. The equity risk premium method relies on the average capital structure over the five-year period *Value Line* uses to estimate beta while the DCF approach uses only current data, so the relevant market value capital structure measure is the most recent that can be calculated. This capital structure is reported in columns [1]-[3] of Tables No. MJV-4 for the electric sample, and MJV-15 for the gas LDC sample.

B. GROWTH RATES

Q13. What growth rates do you use?

A13. For reasons discussed above, historical growth rates today are generally unreliable as forecasts of current investor expectations for the natural gas distribution industry or the electric utility industry. I therefore use rates forecasted by security analysts.

The ideal in a DCF application would be a detailed forecast of future dividends, year by year well into the future, based on a large sample of investment analysts' expectations. I know of no source of such data. Dividends are ultimately paid from earnings, however, and earnings forecasts are available for a few years. Investors do not expect dividends to grow in lockstep with earnings, but for companies for which the DCF approach can be used reliably (*i.e.*, for relatively stable companies whose prices do not include the option-like values described previously), they do expect dividends to track earnings over the long-run. Thus, use of earnings growth rates as a proxy for expectations of dividend growth rates is a common practice.

Accordingly, the first step in my DCF analysis is to examine a sample of investment analysts' forecasted earnings growth rates. For both samples I utilize Bloomberg's BEst

and *Value Line's* forecasted earnings growth.[6] The projected earnings growth rates for the electric sample companies are in Table No. MJV-5, while for the gas LDC companies these rates are presented in Table No. MJV-16.[7] Column [1] of each table reports Bloomberg's BEst analysts' forecasts of the long-term earnings growth for each of the given sample's companies. Column [2] reports the number of analysts that provided a forecast. Columns [3] and [4] report *Value Line's* forecasted earnings per share ("EPS") value for each company for 2008 and 2010-2012 respectively. Column [5] provides *Value Line's* implied long-term growth rate forecast, and column [6] provides a weighted average growth rate for each company across the two sources. (I treat the *Value Line* forecasts as though they overlap exactly with the forecasts from Bloomberg.) These growth rates underlie my simple and multi-stage DCF analyses.

In particular, the five-year average annual growth rate is the perpetual growth rate I employ in the simple DCF model.[8] In the multi-stage model, I rely on the company-specific growth rate until 2012 and on the long-term GDP forecast for year 2017 onwards. During the years from 2012 to 2016, I assume the growth rate converges linearly towards the long-term GDP forecast.[9]

Q14. Do these growth rates correspond to the ideal you mentioned above?

A14. No, not completely. While forecasted growth rates are the quantity required in principle, the forecasts need to go far enough out into the future so that it is reasonable to believe that investors expect a stable growth path afterwards. As can be seen from both Tables No. MJV-5 and MJV-16, the growth rates estimates do not support the view that investors are expecting growth rates equal to the single perpetual growth rate assumed in the simple DCF model. This is particularly striking in the electric sample, where there is

---

[6] The BEst growth rates were downloaded from Bloomberg on April 9, 2007. *Value Line* numbers are their most recent available, variously dated December 29th, 2006, February 9, 2007, and March 2, 2007 for the electric sample, and March 16, 2007 for all gas LDC sample companies but Vectren Corp., which are as of March 30, 2007. (See Tables No. MJV-5 and MJV-16.)

[7] No Bloomberg BEst growth rate was available for MGE Energy Inc. at the time of this document's production.

[8] This growth rate is in column [6] of Tables No. MJV-5 and MJV-16.

[9] For companies in both the electric and gas LDC samples, I use the long-term U.S. GDP growth estimate from *Blue Chip Economic Indicators* (March 10, 2007).

substantial variation across companies' combined growth rates. For example, Cleco Corp and PPL each have a combined growth rate estimate of over 12 percent, while Consolidated Edison's combined estimate is 3.5 percent and Pinnacle West's is 2.9 percent (see column [6], Table No. MJV-5).

In the case of the gas LDCs, the situation is less volatile. The 5-year growth rate estimates for the sample companies are relatively homogeneous with the possible exception of Vectren Corp., which has a combined average growth rate of two percent. This is more than one percent lower than the next lowest estimate. In general, the growth rates estimates for the gas LDC sample are lower than the forecast growth in GDP, which may represent a reaction to the uncertainty in the industry. (See column [6], Table No. MJV-16). The combined forecasts for the remaining gas LDC companies range from 3.3 to 5.9 percent which is generally consistent with the 5.1 percent forecast for the long-term growth rate in GDP.

It should be noted that except for MGE Energy, there are at least two analyst estimates for all of the sample companies, though Cleco Corp, Empire Electric, The Laclede Group and Vectren Corp. have only two. The comparison between the average growth rate forecasts and the growth in GDP indicates that while these growth rate forecasts are not overly optimistic for the gas LDC sample, they may be more so in the case of some electric companies.

Q15. How well are the conditions needed for DCF reliability met at present?

A15. The requisite conditions for the sample companies are not fully met at this time for either sample. Of particular concern for this proceeding is the uncertainty about what investors truly expect the long-run outlook for the sample companies to be. The longest time period available for growth rate forecasts of which I am aware is five years. The long-run growth rate (*i.e.*, the growth rate after the energy industry settles into a steady state, which is certainly *beyond* the next five years for this industry) drives the actual results one gets with the DCF model. Unfortunately, this implies that unless the company or industry in question is stable, so there is little doubt as to the growth rate investors expect,

DCF results in practice can end up being driven by the subjective judgment of the analyst who performs the work.

This is a problem at present because it is hard to imagine that today's energy industry would accurately be described as stable. Inflation and interest rates have largely stabilized over the last 10 years, but oil and natural gas prices have increased dramatically. The prices of natural gas and petroleum have also exhibited a great deal of volatility recently. These factors make demand for natural gas and electricity more uncertain. Additionally, the electric industry as well as both the pipeline industry and the gas distribution sector are going through a series of mergers and acquisitions, which affects the companies' earnings growth rate estimates. This is one reason why companies heavily involved in mergers and acquisitions are normally excluded from the sample. A number of states are actively considering reversing the restructuring process for the electric utility industry. There has also been financial distress among companies specializing in trading natural gas and electricity products which affects both regulated and unregulated companies. Taken together, these factors mean that it may be some time before the energy industry settles into anything investors will see as a stable equilibrium.

Such circumstances imply that a regulator may often be faced with a wide range of DCF numbers, none of which can be well grounded in objective data on true long-run growth expectations, *because no such objective data now exist*. DCF for firms or industries in flux is *inherently* subjective with regard to a parameter (the long-run growth rate) that drives the answer one gets.

It is clear that much longer detailed growth rate forecasts than currently available from Bloomberg and *Value Line* would be needed to implement the DCF model in a completely reliable way for these two samples at this time.

C. DIVIDEND AND PRICE INPUTS

Q16. What values do you use for dividends and stock prices?

A16. Dividends are the last recorded dividend payments as reported by Bloomberg, the 4th-quarter 2006 dividend. This dividend is grown at the estimated growth rate and divided

by the price described below to estimate the dividend yield for the simple and multi-stage DCF models.

For both samples' calculations, stock prices are the average of the closing stock prices for the 15 trading days (approximately three weeks) ending April 9, 2007 for each company, the same date growth rate estimates were pulled from Bloomberg. I do not use a longer period to measure the price, because that would be inconsistent with the principles that underlie the DCF formula. The DCF approach assumes the stock price is the present value of future expected dividends. Stock prices six months or a year ago reflect expectations at that time, which are different from those that underlie the currently available growth forecasts. At the same time, use of an average over a brief period helps guard against a company's price on a particular day price being unduly influenced by mistaken information, differences in trading frequency, and the like.

The closing stock price is used because it is at least as good as any other measure of the day's outcome, and may be better for DCF purposes. In particular, if there were any single price during the day that would affect investors' decisions to buy or sell a stock, I would suspect that it would be each day's closing price, not the high or low during the day. The daily price changes reported in the financial pages, for example, are from close to close, not from high to high or from low to low.

D. COMPANY-SPECIFIC DCF COST OF CAPITAL ESTIMATES

Q17. What DCF estimates do these data yield?

A17. The cost of equity results for the simple and multistage DCF models are shown in Table No. MJV-6 for the electric sample, and Table No. MJV-17 for the gas LDCs. For both samples, Panel A reports the results for the simple DCF method while Panel B reports the results for the multistage DCF method using the long-term GDP growth rate as the perpetual growth rate.

Q18. What overall cost of capital estimates result from the DCF cost of equity estimates?

A18. The capital structure, DCF cost of equity, and cost of debt estimates are combined to obtain the overall after-tax weighted-average cost of capital for each sample company.

These results are presented in Table No. MJV-7 for the electric sample and Table No. MJV-18 for the gas LDCs. Again, Panel A relies on the simple DCF cost of equity results while Panel B relies on the multistage DCF cost of equity results. For the gas LDCs, I also report the average for a sub-sample of companies that have evidenced no apparent data concerns and which appear to be the closest to "pure-plays".[10]

Q19. What information do you report in Tables No. MJV-8 and MJV-19?

A19. These tables report, for each sample, the return on equity consistent with the sample's (and the sub-sample's) estimated overall after-tax weighted-average cost of capital and each Applicant's proposed equity thickness: 55.38 percent for Wisconsin Electric and 52.16 percent for Wisconsin Gas. For both the simple DCF and multistage DCF methods, the sample's average ATWACC is reported in column [1]. Column [6] reports the return on equity as if the sample companies' average market value capital structure had been that of the corresponding Applicant company.

Q20. What are the implications of these results?

A20. The implication of these numbers is discussed in my written evidence, along with the findings of the equity risk premium approach.

[10] Table No. MJV-2 presents information on the percent of regulated assets for the companies in the electric sample as categorized by the Edison Electric Institute. Table No. MJV-13 provides a similar categorization for the companies in the gas LDC sample based upon calculations from the companies' 10-Ks.

EFFECT OF DEBT ON THE COST OF EQUITY

I. AN OVERVIEW OF THE ECONOMIC LITERATURE 1

A. TAX EFFECTS 1
1. Base Case: No Taxes, No Risk to High Debt Ratios 2
2. Corporate Tax Deduction for Interest Expense 3
3. Personal Tax Burden on Interest Expense 4

B. NON-TAX EFFECTS 7

II. EXPANDED EXAMPLE 11

A. DETAILS OF DIFFERENT LEVELS OF DEBT 11

B. THE IMPACT OF INCOME AND INTEREST 15

C. THE EFFECT OF TAXES 18

D. COMBINED EFFECTS 23

Q1. What is the purpose of this Appendix?

A1. In this appendix, I provide details on the effects of debt on the cost of equity. First, I summarize a fairly large body of financial research on capital structure. Second, I provide an extended example to illustrate the effect of debt on the cost of equity.

I. AN OVERVIEW OF THE ECONOMIC LITERATURE

Q2. What is the focus of the economic literature on the effects of debt?

A2. The economic literature focuses on the effects of debt on the value of a firm. The standard way to recognize one of these effects, the impact of the fact that interest expense is tax-deductible, is to discount the all-equity after-tax operating cash flows generated by a firm or an investment project at a weighted average cost of capital, typically known in textbooks as the "WACC." The textbook WACC equals the *market*-value weighted average of the cost of equity and the *after-tax*, *current* cost of debt. However, rate regulation in North America has a legacy of working with another weighted-average cost of capital, the *book*-value weighted average of the cost of equity and the *before-tax*, *embedded* cost of debt. To distinguish the concepts, I refer to the after-tax weighted-average cost of capital as ATWACC.

Q3. How is this section of the appendix organized?

A3. It starts with the tax effects of debt. It then turns to other effects of debt.

A. TAX EFFECTS

Q4. What are the key findings in the literature regarding tax effects?

A4. Three seminal papers are vital for this literature. The first assumes no taxes and risk-free debt. The second adds corporate income taxes. The third adds personal income taxes.

1. Base Case: No Taxes, No Risk to High Debt Ratios

Q5. Please start by explaining the simplest case of the effect of debt on the value of a firm.

A5. The "base case," no taxes and no costs to excessive debt, was worked out in a classic 1958 paper by Franco Modigliani and Merton Miller, two economists who eventually won Nobel Prizes in part for their body of work on the effects of debt.[1] Their 1958 paper made what is in retrospect a very simple point: if there are no taxes and no risk to the use of excessive debt, use of debt will have no effect on a company's operating cash flows (i.e., the cash flows to investors as a group, debt plus equity combined). If the operating cash flows are the same regardless of whether the company finances mostly with debt or mostly with equity, then the value of the firm cannot be affected at all by the debt ratio. In cost of capital terms, this means the overall cost of capital is constant regardless of the debt ratio, too.

In the base case, issuing debt merely divides the cash flows into two pools, one for bondholders and one for shareholders. If the divided pools have different priorities in claims on the cash flows, the risks and costs of capital will differ for each pool. But the risk and overall cost of capital of the entire firm, the sum of the two pools, is constant regardless of the debt ratio. Thus,

$$r_1^* = r_{A1} \qquad \text{(E-1a)}$$

where r^*_1 is the overall after-tax cost of capital at any particular capital structure and r_{A1} is the all-equity cost of capital for the firm. (The "1" subscripts distinguish the case where there are no taxes from subsequent equations that consider first corporate and then both corporate and personal taxes.) With no taxes and no risk to debt, the overall cost of capital does not change with capital structure.

This implies that the relationship of the overall cost of capital to the component costs of debt and equity is

[1] Franco Modigliani and Merton H. Miller (1958), "The Cost of Capital, Corporation Finance and the Theory of Investment," *American Economic Review*, 48, pp. 261-297.

$$r_{E1} \times \left(\frac{E}{V}\right) + r_{D1} \times \left(\frac{D}{V}\right) = r_1^* \quad \text{(E-1b)}$$

with the overall cost of capital (r^*) on the *right* side, as the *independent* variable, and the costs of equity (r_E) and debt (r_D) on the left side, as *dependent* variables determined by the overall cost of capital and by the capital structure (i.e., the shares of equity (E) and debt (D) in overall firm value (V=E+D)) that the firm happens to choose. Note that if equation (E-1a) were correct, the equation that solved it for the cost of equity would be,

$$r_{E1} = r_1^* + (r_1^* - r_D) \times \left(\frac{D}{E}\right) \quad \text{(E-1c)}$$

Note also that (D/E) gets exponentially higher in this equation as the debt-to-value ratio increases[2] i.e., the cost of equity increases exponentially with leverage.

2. Corporate Tax Deduction for Interest Expense

Q6. What happens when you add corporate taxes to the discussion?

A6. If corporate taxes exist with risk-free debt (and if only taxes at the corporate level matter, not taxes at the level of the investor's personal tax return), the initial conclusion changes. Debt at the corporate level reduces the company's tax liability by an amount equal to the marginal tax rate times interest expense. All else equal, this will add value to the company because more of the operating cash flows will end up in the hands of investors as a group. That is, if only corporate taxes mattered, interest would add cash to the firm equal to the corporate tax rate times the interest expense. This increase in cash would increase the value of the firm, all else equal. In cost of capital terms, it would reduce the overall cost of capital.

How much the value of the firm would rise and *how far* the overall cost of capital would fall would depend in part on how often the company adjusts its capital structure, but this is a second-order effect in practice. (The biggest effect would be if companies could issue riskless perpetual debt, an assumption Profs. Modigliani and Miller explored in

[2] For example, at 20-80, 50-50, and 80-20 debt-equity ratios, (D/E) equals, respectively, (20/80) = 0.25, (50/50) = 1.0, and (80/20) = 4.0. The extra 30 percent of debt going from 20-80 to 50-50 has much less impact on (D/E) [i.e., by moving it from 0.25 to 1.0] than the extra 30 percent of debt going from 50-50 to 80-20 [i.e., by moving it from 1.0 to 4.0]. Since the cost of equity equals a constant risk premium times the debt-equity ratio, the cost of equity grows ever more rapidly as you add more and more debt.

1963, in the second seminal paper;[3] this assumption could *not* be true for a real company.) Prof. Robert A. Taggart provides a unified treatment of the main papers in this literature and shows how various cases relate to one another.[4] Perhaps the most useful set of benchmark equations for the case where only corporate taxes matter are:

$$r_2^* = r_{A2} - r_D \times t_C \times \left(\frac{D}{V}\right) \quad \text{(E-2a)}$$

$$r_2^* = r_{E2} \times \left(\frac{E}{V}\right) + r_D \times \left(\frac{D}{V}\right) \times (1 - t_C) \quad \text{(E-2b)}$$

which imply for the cost of equity,

$$r_{E2} = r_{A2} + (r_{A2} - r_D) \times \left(\frac{D}{E}\right) \quad \text{(E-2c)}$$

where the variables have the same meaning as before but the "2" subscripts indicate the case that considers corporate but not personal taxes.

Note that Equation (E-2a) implies that when only corporate taxes matter, the overall after-tax cost of capital declines steadily as more debt is added, until it reaches a minimum at 100 percent debt (i.e., when D/V = 1.0). Note also that Equation (E-2c) still implies an exponentially increasing cost of equity as more and more debt is added. In fact, except for the subscript, Equation (E-2c) looks just like Equation (E-1c).

However, whether any value is added and whether the cost of capital changes at all also depends on the effect of taxes at the personal level.

3. Personal Tax Burden on Interest Expense

Q7. How do personal taxes affect the results?

A7. Ultimately, the purpose of investment is to provide income for consumption, so personal taxes affect investment returns. For example, in the U.S., municipal bonds have lower interest rates than corporate bonds because their income is taxed less heavily at the

---

[3] Franco Modigliani and Merton H. Miller (1963), "Corporate Income Taxes and the Cost of Capital: A Correction," *American Economic Review*, 53, pp. 433-443.

[4] Robert A. Taggart, Jr. (1991), "Consistent Valuation and Cost of Capital Expressions with Corporate and Personal Taxes," *Financial Management* 20, pp. 8-20.

personal level. In general, capital appreciation on common stocks is taxed less heavily than interest on corporate bonds because (1) taxes on unrealized capital gains are deferred until the gains are realized, and (2) the capital gains tax rate is lower. Dividends are taxed less heavily than interest, also, under current tax law.[5] The effects of personal taxes on the cost of common equity are hard to measure, however, because common equity is so risky.

Professor Miller, in his Presidential Address to the American Finance Association,[6] explored the issue of how personal taxes affect the overall cost of capital. The paper pointed out that personal tax effects could offset the effect of corporate taxes entirely.

Q8. Is it likely that the effect of personal taxes will completely neutralize the effect of corporate taxes?

A8. I do not believe so, although the likelihood of such a result would be increased if the current federal tax reductions on dividends and capital gains became permanent rather than expiring in 2010. However, personal taxes are important even if they do not make the corporate tax advantage on interest vanish entirely. Capital gains and dividend tax advantages definitely convey some personal tax advantage to equity, and even a partial personal advantage to equity reduces the corporate advantage to debt.

The Taggart paper explores the case of a partial offset, also. With personal taxes, the risk-free rate on the security market line is the after-personal-tax rate, which must be equal for risk-free debt and risk-free equity.[7] Therefore, the pre-personal-tax risk-free rate for equity will generally not be equal to the pre-personal-tax risk-free rate for debt. In particular, $r_{fE} = r_{fD} \times [(1-t_D)/(1-t_E)]$, where r_{fE} and r_{fD} are the risk-free costs of equity and debt and t_E and t_D are the personal tax rates for equity and debt, respectively. In

[5] The current maximum personal tax rate on dividend income was extended to the end of 2010 by the President on May 17, 2006. It is uncertain whether the reduced rates on dividend income will be further extended.

[6] Merton H. Miller (1977), "Debt and Taxes," *The Journal of Finance*, 32: 261-276, the third of the seminal papers mentioned earlier.

[7] As Prof. Taggart notes (his footnote 9), it is not necessary that a specific, risk-free equity security exist as long as one can be created synthetically, through a combination of long and short sales of traded assets. Such constructs are a common analytical tool in financial economics.

terms of the cost of debt, the Taggart paper's results imply that a formal statement of these effects can be written as:[8]

$$r_3^* = r_{A3} - r_D \times t_N \times \left(\frac{D}{V}\right) \quad \text{(E-3a)}$$

$$= r_{E3} \times \left(\frac{E}{V}\right) + r_D \times \left(\frac{D}{V}\right) \times (1 - t_C) \quad \text{(E-3b)}$$

which imply

$$r_{E3} = r_{A3} + \left[r_{A3} - r_D \times \left(\frac{1-t_D}{1-t_E}\right)\right] \times \left(\frac{D}{E}\right) \quad \text{(E-3c)}$$

Suppose, for example, that t_C = 0.35 percent, t_E = 7.7 percent and t_D = 40 percent. Then $[(1-t_D)/(1-t_E)] = 0.65 = (1-t_C)$. That condition corresponds to Miller's 1977 paper, in which the net personal tax advantage of equity fully offsets the net corporate tax advantage of debt. Note also that in that case, $t_N = 0$.[9] Therefore, if the personal tax advantage on equity fully offsets the corporate tax advantage on debt, Equation (E-3a) confirms that the overall after-tax cost of capital is a constant.

However, it is unlikely that the personal tax advantage of equity fully offsets the corporate tax advantage of debt. If taxes were all that mattered (i.e., if there were no other costs to debt), the overall after-corporate-tax cost of capital would still fall as debt was added, just not as fast.

Finally, note that the overall after-tax cost of capital, Equation (E-3b), still uses the corporate tax rate even when personal taxes matter. Equations (E-2b) and (E-3b) both correspond to the usual formula for the ATWACC. Personal taxes affect the way the cost of equity changes with capital structure -- Equation (E-3c) -- but not the formula for the overall after-tax cost of capital given that cost of equity.

---

[8] The net all-tax effect of debt on the overall cost of capital, t_N, equals $\{[t_C+t_E-t_D-(t_C \times t_E)] / (1-t_E)\}$, where t_D is the personal tax rate on debt, as before. This measure of net tax effect is designed for use with the cost of debt in Equation (E-3a), which seems more useful in the present context. The Taggart paper works with a similar measure, but one which is designed for use with the cost of risk-free equity in the equivalent Taggart equation.

[9] In the above example, $t_N = \{[0.35+0.077-0.4-(0.35 \times 0.077)] / (1.0-0.077)\} = 0.0/0.923 = 0$.

B. NON-TAX EFFECTS

Q9. Please describe the non-tax effects of Debt.

A9. If debt is truly valuable, firms should use as much as possible, and competition should drive firms in a particular industry to the same, optimal capital structure for the industry. If debt is harmful on balance, firms should avoid it. Neither picture corresponds to what we actually see. A large economic literature has evolved to try to explain why.

Part of the answer clearly is the costs of excessive debt. Here the results cannot be reduced to equations, but they are no less real for that fact. As companies add too much debt, the costs come to outweigh the benefits. Too much debt reduces or eliminates financial flexibility, which cuts the firm's ability to take advantage of unexpected opportunities or weather unexpected difficulty. Use of debt rather than internal financing may be taken as a negative signal by the market.

Even if the company is generally healthy, more debt increases the risk that the company cannot use all of the interest tax shields in a bad year. As debt continues to grow, this problem grows and others may crop up. Management begins to worry about meeting debt payments instead of making good operating decisions. Suppliers are less willing to extend trade credit, and a liquidity shortage can translate into lower operating profits. Ultimately, the firm might have to go through the costs of bankruptcy and reorganization. Collectively, such factors are known as the costs of "financial distress."[10]

The net tax advantage to debt, if positive, is affected by costs such as a growing risk that the firm might have to bear the costs of financial distress. First, the expected present value of these costs offsets the value added by the interest tax shield. Second, since the likelihood of financial distress is greater in bad times when other investments also do poorly, the possibility of financial distress will increase the risks investors bear. These effects increase the variability of the value of the firm. Thus, firms that use too much debt can end up with a higher overall cost of capital than those that use none.

---

[10] See, for example, Section 18.3 of Brealey, Myers and Allen, 2006, *Principles of Corporate Finance*, 8th Edition, McGraw-Hill/Irwin, 2006.

Other parts of the answer include the signals companies send to investors by the decision to issue new securities, and by the type of securities they issue. Other threads of the literature explore cases where management acts against shareholder interests, or where management attempts to "time" the market by issuing specific securities under different conditions. For present purposes, the important point is that no theory, whether based on taxes or on some completely different issue, has emerged as "the" explanation for capital structure decisions by firms. Nonetheless, despite the lack of a single "best" theory, there is a great deal of relevant empirical research.

Q10. What does that research show?

A10. The research does not support the view that debt makes a material difference in the value of the firm, at least not once a modest amount of debt is in place. If debt were truly valuable, competitive firms should use as much debt as possible short of producing financial distress, and competitive firms that use less debt ought to be less profitable. The research shows exactly the opposite.

For example, Kester[11] found that firms in the same industry in both the U.S. and Japan do not band around a single, "optimal" capital structure, and the most profitable firms are the ones that use the *least* debt. This finding comes despite the fact that both countries at the time (unlike the U.S. currently) had fully "classical" tax systems, in which dividends are taxed fully at both the corporate and personal level. Wald[12] confirms that high profitability implies low debt ratios in France, Germany, Japan, the U.K., and the U.S. Booth *et al.* find the same result for a sample of developing nations.[13] Fama and French[14] analyze over 2000 firms for 28 years (1965-1992, inclusive) and conclude, "Our

[11] Carl Kester (1986), "Capital and Ownership Structure: A Comparison of United States and Japanese Manufacturing Concerns," *Financial Management*, 15:5-16.

[12] John K. Wald (1999), "How Firm Characteristics Affect Capital Structure: An International Comparison," *Journal of Financial Research*, 22:161-167.

[13] Laurence Booth *et al.* (2001), "Capital Structures in Developing Countries," *The Journal of Finance* Vol. LVI, pp. 87-130, finds at p. 105 that "[o]verall, the strongest result is that profitable firms use less total debt. The strength of this result is striking ..."

[14] Eugene F. Fama and Kenneth R. French (1998), "Taxes, Financing Decisions and Firm Value," *The Journal of Finance*, 53:819-843.

tests thus produce no indication that debt has net tax benefits."[15] A paper by Graham[16] carefully analyzes the factors that might have led a firm not to take advantage of debt. It confirms that a large proportion of firms that ought to benefit substantially from use of additional debt, including large, profitable, liquid firms, appear not to use it "enough."

This research leaves us with only three options: either (1) apparently good, profit-generating managers are making major mistakes or deliberately acting against shareholder interests, (2) the benefits of the tax deduction on debt are less than they appear, or (3) the non-tax costs to use of debt offset the potential tax benefits. Only the first of these possibilities is consistent with the view that the tax deductibility of debt conveys a material cost advantage. Moreover, if the first explanation were interpreted to mean that otherwise good managers are acting against shareholder interests, either deliberately or by mistake, it would require the additional assumption that their competitors (and potential acquirers) let them get away with it.

Q11. Are there any explanations in the financial literature for this puzzle other than stupid or self-serving managers at the most profitable firms?

A11. Yes. For example, Stewart C. Myers, a leading expert on capital structure, made it the topic of his Presidential Address to the American Finance Association.[17] The poor performance of tax-based explanations for capital structure led him to propose an entirely different mechanism, the "pecking order" hypothesis. This hypothesis holds that the net tax benefits of debt (i.e., corporate tax advantage over personal tax disadvantage) are at most of a second order of importance relative to other factors that drive actual debt decisions.[18] Similarly, Baker and Wurgler (2002)[19] observe a strong and persistent

[19] Malcolm Baker and Jeffrey Wurgler (2002), "Market Timing and Capital Structure," *The Journal of Finance* 57:1-32.

impact that fluctuations in market value have on capital structure. They argue that this impact is not consistent with other theories. The authors suggest a new capital structure theory based on market timing -- capital structure is the cumulative outcome of attempts to time the equity market.[20] In this theory, there is no optimal capital structure, so market timing financing decisions just accumulate over time into the capital structure outcome. (Of course, this theory only makes sense if investors do not recognize what managers are doing.)

Q12. Do inter-firm differences within an industry explain the wide variations in capital structure across the firms in an industry?

A12. No. This view is contradicted by the empirical research. As mentioned before, it has long been found that the most profitable firms in an industry, i.e., those in the best position to take advantage of debt, use the least.[21] Graham (2000) carefully examines differences in firm characteristics as possible explanations for why firms use "too little" debt and concludes that such differences are *not* the explanation: firms that ought to benefit substantially from more debt by all measurable criteria, if the net tax advantage of debt is truly valuable, voluntarily do not use it.[22]

Nor does the research support the view that firms are constantly trying to adjust their capital structures to optimal levels. Additional research on the pecking order hypothesis demonstrates that firms do not tend towards a target capital structure, or at least do not do so with any regularity, and that past studies that seemed to show the contrary actually lacked the power to distinguish whether the hypothesis was true or not.[23] In the words of

---

[20] *Ibid.*, p. 29.

[21] For example, Kester, *op. cit.* and Wald, *op. cit.*

[22] While not contradicting Graham's finding that differences in firm characteristics do not explain capital structure differences, Nengjiu Ju, Robert Parrino, Allen M. Poteshman, and Michael S. Weisbach, "Horses and Rabbits? Trade-Off Theory and Optimal Capital Structure," *Journal of Financial and Quantitative Analysis*, June 2005, pp. 1-24, looks at the issue in a different manner. Their paper uses a dynamic rather than static model to analyze the tradeoff between the tax benefits of debt and the risk of financial distress. It finds that bankruptcy costs by themselves are enough to explain observed capital structures, once dynamic effects are considered. This means debt is not as valuable as suggested by the traditional static analysis (of the sort used by Graham).

the Shyam-Sunder - Myers paper p. 242, "If our sample companies did have well-defined optimal debt ratios, it seems that their managers were not much interested in getting there."

II. EXPANDED EXAMPLE

Q13. What topics do you cover in this section?

A13. The discussion in my testimony did not detail the impact of different starting points for the level of debt nor did it address income earned on the investment, interest expense, or taxes. This section covers these topics. First, it discusses how the level of debt affects the cost of equity. Second, it addresses the influence of income and interest on the investment. Third, it explains the impact of taxes on capital structure decisions. The final topic covered in this section is the combined consequence of tax and non-tax effects of debt.

A. DETAILS OF DIFFERENT LEVELS OF DEBT

Q14. Why does more debt mean more risk for equity holders?

A14. Debt magnifies the variability of the equity return. As a simple example, think of an investor who takes money out of her savings and invests $100,000 in real estate. The future value of the real estate is uncertain. If the real estate market booms, she wins. If the real estate market goes down, she loses. Figure E-1 below illustrates this.

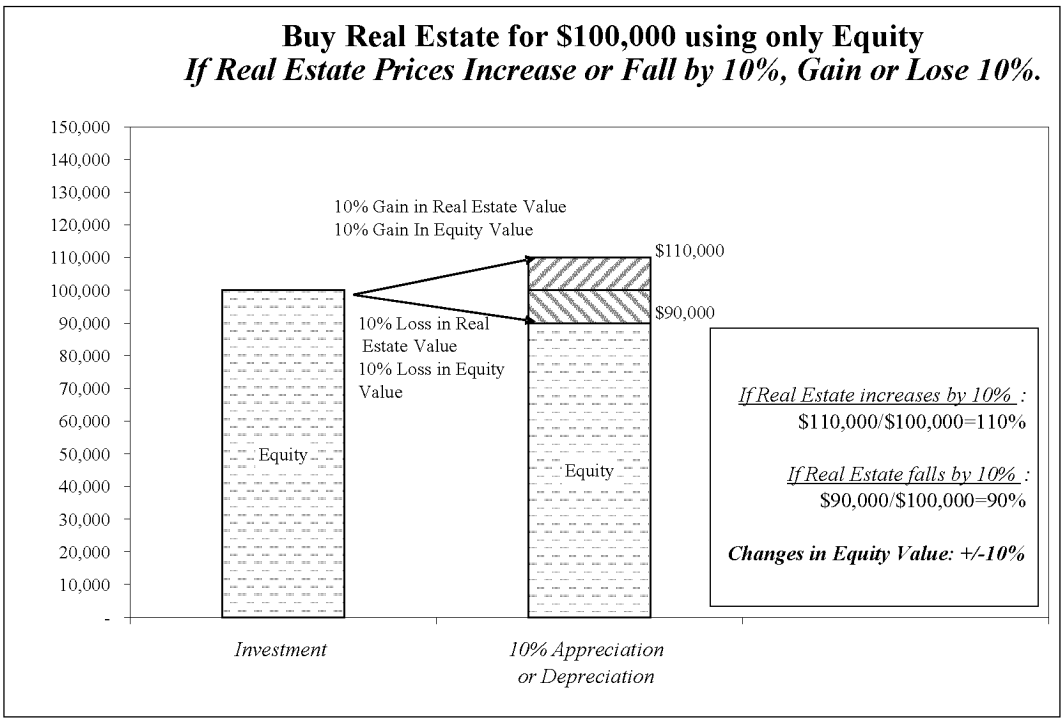

Figure E-1

In the scenario above, the investor financed her real estate purchase through 100 percent equity. Suppose instead that the investor had financed 50 percent of her real estate investment with a mortgage of $50,000. The mortgage lender does not expect to share in any benefits from increases in real estate values. Neither does the mortgage lender expect to share in any losses from falling real estate values, i.e., the investor carries the entire risk of fluctuating real estate prices. Figure E-2 illustrates this effect.

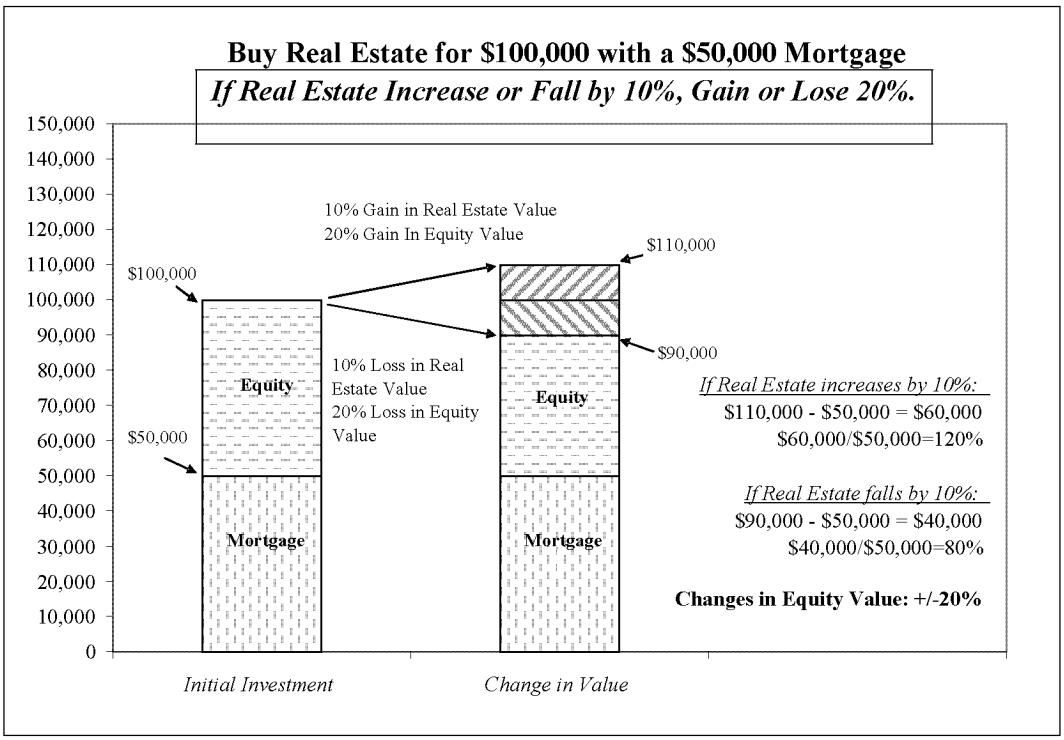

Figure E-2

In Figure E-2 where the investor financed her purchase through 50 percent equity and 50 percent debt, the variability in the investor's equity return is two times greater than that of Figure E-1. The entire fluctuation of 10 percent from rising or falling real estate prices falls on the investor's $50,000 equity investment. The lesson from the example is obvious, debt adds risk to equity.

Q15. What happens if the investor finances the real estate purchase with different proportions of debt?

A15. The equity return becomes more variable when the mortgage percentage is a greater proportion of the initial price. Table E-1 below calculates the return on equity when real estate prices increase by 10 percent when mortgages are 0 percent, 30 percent, 50 percent, and 70 percent of the initial price.

Table E-1: The Impact of Leverage on the Return on Equity

	100% Equity	70% Equity	50% Equity	30% Equity
Debt	$0	$30,000	$50,000	$70,000
Original Equity Investment	$100,000	$70,000	$50,000	$30,000
Increase in Market Value of Equity	$10,000	$10,000	$10,000	$10,000
Return on Equity Investment	10%	14.3%	20%	33.3%

Note that going from 70 percent equity down to 50 percent equity increases the return on the equity investment by 5.7 percent while going from 50 percent equity to 30 percent equity increases the return on equity by 13.3 percent. This illustrates a general point; the rate of return on equity increases more quickly at higher levels of debt than at lower levels. Investors demand a higher equity rate of return to bear more risk and debt magnifies equity's risk at an ever increasing rate. Therefore, the required equity rate of return goes up at an ever increasing rate as debt is added. This is not only basic finance theory, it is the everyday experience of anyone who buys a home. The bigger the mortgage, the more percentage risk the equity faces from changes in housing prices.

Q16. Please provide an example that illustrates why market values are relevant.

A16. Suppose in the above example that the investor has invested in real estate 10 years ago. Further assume that depreciation has reduced the book value of the real estate from $100,000 to $75,000 and assume the investor has paid off 40 percent of his $50,000 mortgage. Thus, the investor has a remaining mortgage of $30,000 (= 60% × $50,000). The book value of the investor's equity investment is therefore $45,000 (= $75,000 - $30,000).

What happens now if real estate prices rise or fall 20 percent? To answer that question, we need to know how real estate prices have developed over the past 10 years. If the market value of the real estate now is $200,000 then a 20 percent decrease in the price of real estate ($40,000) is almost equal to the investor's book value equity. However, his

market value equity (or net worth) is equal to the value of the real estate minus what he owes on the mortgage. If we assume that the market value of the mortgage equals the unpaid balance ($30,000), then the investor's net worth is calculated as follows:

Net Worth	=	Market Value of Real Estate	-	Remaining Mortgage
	=	$200,000	-	$30,000
	=	$170,000		

Therefore, the rate of return on equity due to a 20 percent decline in real estate prices is calculated in Table E-2.

Table E-2: Calculating the Rate of Return on Equity

Decline in Real Estate Value	$40,000
Market-Value Equity	$170,000
Rate of Return on Equity	- $40,000/$170,000 = -23.5%

B. THE IMPACT OF INCOME AND INTEREST

Q17. How does earning income from the investment and paying interest on debt affect the results?

A17. In the following explanation, I ignore income taxes which I deal with in Section C. Assume the investor is receiving income, e.g., rent, from the real estate. Specifically, assume the investor receives $500 per month in income after all non-interest expenses ($6,000 per year). Also, assume that the expected appreciation is 5 percent per year, so the expected market value is $105,000 after one year. Then the expected rate of return from the real estate with all equity financing is:

$$\text{Expected Return on Equity @ 0\% debt} = \frac{\text{Expected Net Income + Expected Appreciation}}{}$$

$$\text{Initial Investment} = \frac{\$6{,}000 + (\$105{,}000 - \$100{,}000)}{\$100{,}000} = 11\%$$

Now suppose that the mortgage interest rate were 5 percent. Then at a mortgage equal to 50 percent, or $50,000, interest expense would be ($50,000 x 0.05), or $2,500. The expected equity rate of return would be:

$$\text{Expected Return on Equity @ 50\% debt} = \frac{\text{Expected (Net Income + Appreciation) – Int. Expense}}{\text{Initial } \textit{Equity} \text{ Investment}} = \frac{\$6{,}000 + \$5{,}000 - \$2{,}500}{\$50{,}000} = 17\%$$

Notice that the expected return on equity is higher as is the risk carried by equity.

Q18. Can you provide a more general illustration?

A18. Yes. Figure E-3 uses these assumptions at different mortgage levels to plot both (i) the expected rate of return on the equity in the dwelling, and (ii) the realized rate of return on

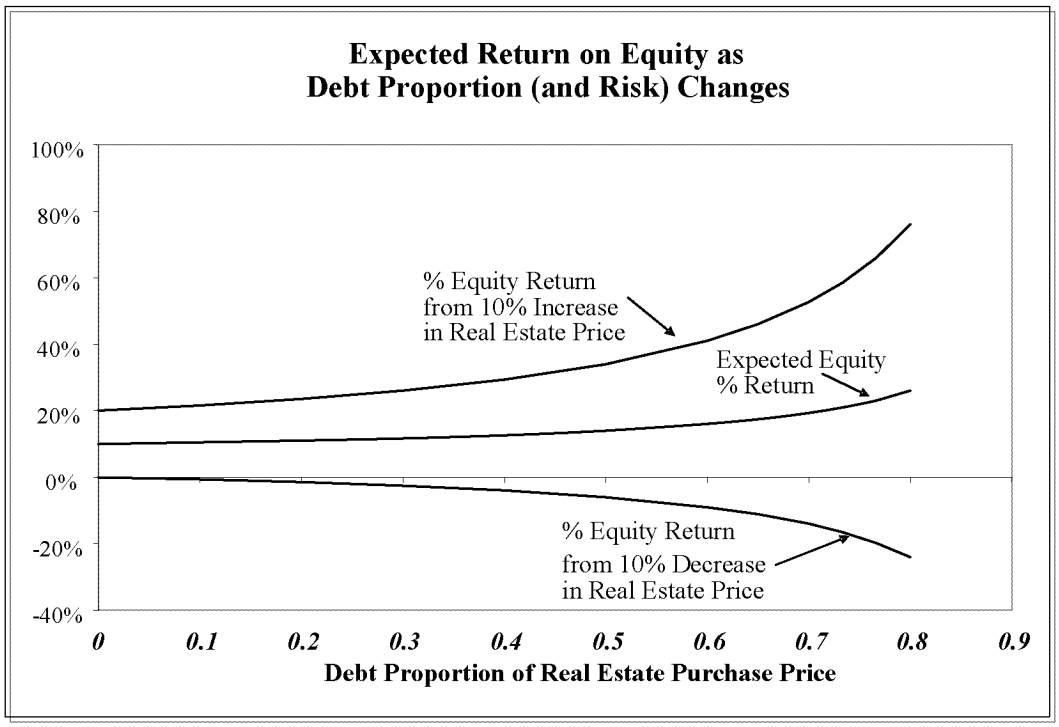

Figure E-3

that equity in a year if the dwelling value increases by 10 percent more than the expected 5 percent rate (i.e., if the value increases by 15 percent) or by 10 percent less than expected (i.e., if it decreases by 5 percent).[24]

The expected rate of return on equity increases at an increasing rate as the investor finances more and more of the real estate through loans (e.g., with a mortgage). Since equity bears all the risk of increases or decreases in real estate values (absent financial distress or bankruptcy), the amount of risk the buyer bears grows at an ever increasing rate as the mortgage percentage also increases.

Q19. What are the implications of this example?

A19. Any time an individual or a company uses debt to finance part an investment, the same risk magnifies. For example, if an investor buys stocks "on margin" -- by borrowing part of the money used to buy the stock -- the expected rate of return will be higher as will the risks the investor carries. As an everyday example, imagine investing your retirement

savings in a stock portfolio bought with as much margin as possible. If you were lucky, you could end up living very well in retirement. But you would be taking a lot of risk on the opposite outcome, since your portfolio could decline by more than 100 percent of your initial investment.

The same risk-magnifying effects happen when companies borrow to finance part of their investments.

C. THE EFFECT OF TAXES

Q20. What is the impact of taxes?

A20. Analyzing the net effect of taxes in capital structure decisions by corporations is an important part of the financial research. (Other parts of that research address such issues as the risk of financial distress or bankruptcy, and the signals corporations send investors by the choice of how to finance new investments.) The bottom line is that taxes complicate the picture without changing the basic conclusion.

Q21. Please describe the potential impact of taxes.

A21. Interest expense is tax-deductible for corporations. That increases the pool of cash the corporation gets to keep out of its operating earnings (i.e., its earnings before interest expense). With no debt, 100 percent of operating income is subject to taxes. With debt, only the equity part of the operating income is subject to taxes.

All else equal, the extra money kept from operating income increases the value of the corporation. The standard way to recognize that increase in value is to use an after-tax weighted-average cost of capital as a discount rate when valuing a company's operating cash flows.

Q22. Do personal taxes affect the value of debt, too?

A22. Yes, but in the other direction. One offset to debt's tax benefits at the corporate level is its higher tax burden at the personal level. Investors care about the money they get to

[24] For simplicity, the figure assumes the debt's interest rate is independent of the debt proportion. This might not always be true, and in general would not be true for a corporation that issued debt. However, the

keep after all taxes are paid, and while the corporation saves taxes by opting for debt over equity, individuals pay more taxes on interest than on capital gains from equity (and for now, on dividends as well).

Q23. Are there factors other than taxes matter?

A23. Absolutely, "all else" does not remain equal as more debt is added. The more debt, the more the non-tax effects of debt offset the tax benefits. Other costs include such effects as a loss of flexibility, the possibility of sending negative signals to investors, and a host of costs and risks associated with the danger of financial distress.

Q24. Does the tradeoff between the tax and non-tax effects of debt mean that firms have well-defined, optimal capital structures?

A24. No, this sort of "tradeoff" model does not explain actual corporate behavior. A substantial body of economic research confirms that real-world corporations act as if, after a moderate amount of debt is in place, the tax benefits of debt are not worth debt's other costs. In country after country and in industry after industry, the most profitable corporations in an industry tend to use the least debt. The research on this point is quite thorough, and the finding that the most profitable companies tend to use the least debt in a given industry is robust. Yet these are the companies with the most operating income to shield from taxes, who would benefit most if interest tax shields were truly valuable net of debt's other costs. They also presumptively are the best-managed on average (else why are they the most profitable?). This means it is unrealistic to suppose that more debt is always better, or that greater tax savings due to higher interest expense always add value to the firm on balance.

Q25. If the tradeoff model doesn't explain capital structure decisions by firms, is there a model that does?

A25. No single model has (yet) emerged as 'the" explanation of capital structure. However, several alternative models attempt to model the tradeoff (e.g., the "pecking order" hypothesis and "agency cost" explanations).

---

general shape of the graphs remains the same.

Q26. What does the absence of an agreed theory of capital structure in the financial literature imply about the overall effect of debt on the value of the firm?

A26. The findings of the financial literature mean that within an industry, there is no well-defined optimal capital structure. The use of some debt does convey some value advantage in most industries, but that advantage is offset by other costs as firms add more debt.[25] The range of capital structures over which the value of the firm in any industry is maximized is wide and should be treated as flat. The location and level of that range, however, does vary from industry to industry, just as the overall cost of capital varies from industry to industry.

Figure E-4 illustrates the picture that emerges from the research. This figure shows the present value of an investment in each of four different industries. For simplicity, the investment is expected to yield $1.00 per year forever. For firms in relatively high-risk industries (Industry 1 in the graph, the lowest line), the $1.00 perpetuity is not worth much and any use of debt decreases firm value. For firms in relatively low-risk industries (Industry 4 in the graph), the perpetuity is worth more and substantial amounts of debt make sense. Industries 2 and 3 are intermediate cases.

The maximum net rate at which taxes can increase value in this figure equals 20 percent of interest expense, representing a balance between the corporate tax advantage to debt and the personal tax disadvantage. The figure plots the maximum possible impact of taxes on value as a separate line, starting at the all-equity value of the lowest-risk industry (Industry 4).

[25] Note that if debt did increase the value of the firm materially, competition would tend to take that value away, since issuing debt is an easy-to-copy competitive strategy. Prices would fall as firms copied the strategy, lowering operating earnings and passing the net tax advantages to debt through to customers (just as happens under rate regulation). Therefore, if also there were a narrow range of optimal capital structures within an industry, competition would drive all firms in the industry to capital structures within that range. This does not happen in practice, which contradicts one or both of the assumptions, i.e., (1) that debt adds material value on balance, and/or (2) that there is a narrow range of optimal capital structures.

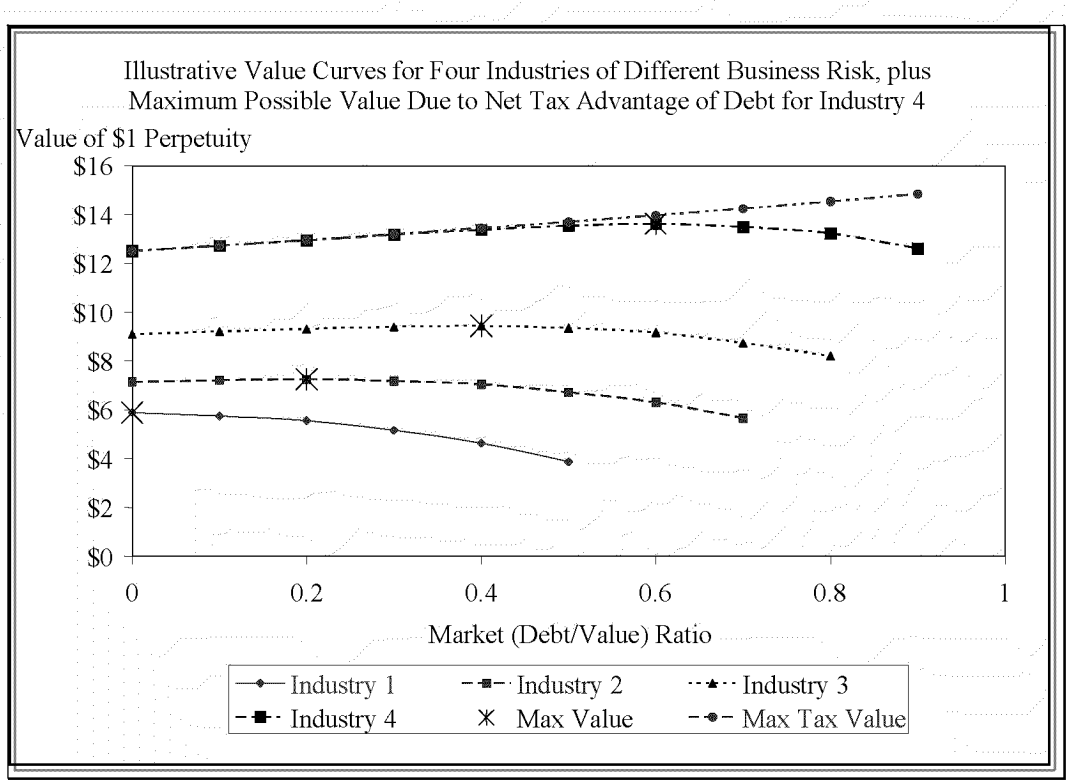

Figure E-4

Figure E-4 identifies a particular point as the maximum value on each of the four curves. However, the research shows that reliable identification of this maximum point, except in the extreme case where no debt should be used, is impossible. In accord with the research, the graph is prepared so that in none of the industries does a change in capital structure make much difference near the top of the curve. Even Industry 4, which increases in value at the maximum rate as quite a lot of debt is added, eventually must reach a broad range where changes in the debt ratio make little difference to firm value, given the research. For Industry 4, debt makes less than a 2 percent difference in the total value of the firm for debt-to-value ratios between 40 and 70 percent. (While these particular values are illustrative, numbers of this order of magnitude are the only ones consistent with the research.)

Q27. What does this imply for the overall cost of capital?

A27. Figure E-5 plots the after-tax weighted-average costs of capital ("ATWACCs") that correspond to the value curves in Figure E-4. This picture just turns Figure E-4 upside

down.[26] All the same conclusions remain, except that they are stated in terms of the overall cost of capital instead of the overall firm value. In particular, except for high-risk industries, the overall cost of capital is essentially flat across a broad middle range of capital structures for each industry, which is the only outcome consistent with the research. For Industry 4, for example, the ATWACC changes by less than 15 basis points for debt-to-value ratios between 40 and 70 percent.

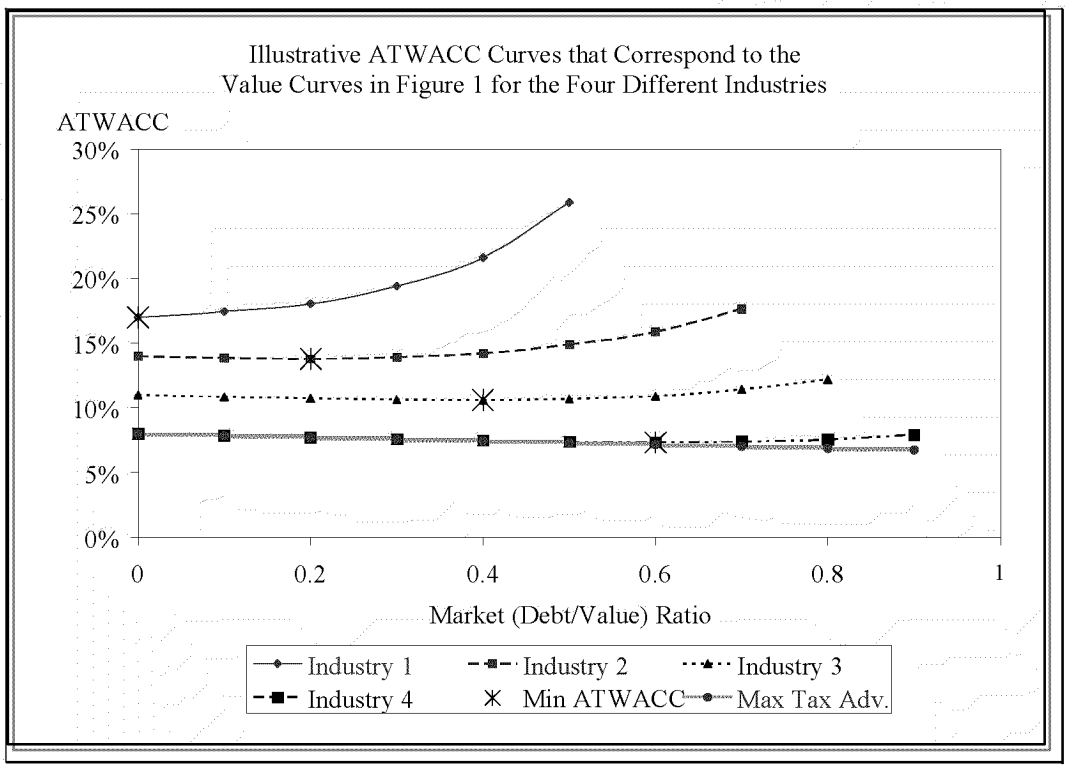

Figure E-5

Q28. How does this discussion relate to estimation of the right cost of equity for ratemaking purposes?

A28. When an analyst estimates the cost of equity for a sample of companies, s/he does so at the sample's actual market-value capital structure. That is, the sample evidence corresponds to ATWACCs that are already out somewhere in the broad middle range in

[26] Note that the actual estimated ATWACC at higher debt ratios will tend to underestimate the ATWACC that corresponds to the value curves in Figure E-4, which are depicted in Figure E-5, and so will tend to overestimate the value of debt to the firm. The reason is that some of the non-tax effects of excessive debt, such as a loss of financial flexibility, may be hard to detect and not show up in cost of capital measurement.

which changes in the debt ratio have little or no impact on the overall value of the firm or the ATWACC.

An analyst therefore should assume the ATWACCs for the sample companies are literally flat. This assumption always provides the exact tradeoff between the cost of equity and capital structure at the literal minimum of the company's ATWACC curve. The research shows that this minimum is actually a broad, flat region, as depicted above. If the company happens to be somewhat to one side or the other of the literal minimum within this region, the recommended procedure may lead to a small understatement or overstatement of the amount that the cost of equity will change as capital structure changes. The degree of this under- or overstatement, however, is very small compared to the inherent uncertainty in estimating the cost of equity in the first place. Otherwise, the financial research would have found very different results about the existence of a narrowly defined optimal capital structure.

D. COMBINED EFFECTS

Q29. Please summarize the implications for the combined impact of the tax and non-tax effects of debt.

A29. The most profitable firms do not behave as if the precise amount of debt they use makes any material difference to value, and competition does not force them into an alternative decision, as it would if debt were genuinely valuable. The explanation that fits the facts and the research is that within an industry, there is no well-defined optimal capital structure. Use of some debt does convey an advantage in most industries, but that advantage is offset by other costs as firms add more debt. The range of capital structures over which the value of the firm in any industry is maximized is wide and should be treated as flat. The location and level of that range, however, does vary from industry to industry, just as the overall cost of capital varies from industry to industry. To conclude that more debt does add more value, once the firm is somewhere in the normal range for the industry, is to conclude that corporate management in general is either blind to an easy source of value or otherwise incompetent (and that their competitors let them get away with it).

The finding that there is no narrowly defined optimal capital structure implies that analysts should estimate the ATWACCs for a sample of companies in a given industry and treat the average ATWACC value as independent of capital structure (at least within a broad middle range of capital structures). The right cost of equity for a rate-regulated company in the same industry is the number that yields the same ATWACC at the capital structure used to set the revenue requirement, since that is the cost of equity that (estimation problems aside) the sample companies would have had if their market-value capital structures had been equal to the regulatory capital structure.

I. INTRODUCTION AND SUMMARY

Q1. Please state your name and address for the record.

A1. My name is Michael J. Vilbert. My business address is *The Brattle Group*, 44 Brattle Street, Cambridge, MA 02138, USA.

Q2. Did you previously file testimony in this proceeding?

A2. Yes, I filed Direct Testimony ("Vilbert Direct") on behalf of Wisconsin Electric Power Company ("Wisconsin Electric" or "WEPCO") and Wisconsin Gas LLC ("Wisconsin Gas" or "WG"), jointly the Applicants, in May 2007 regarding return on equity that the Applicants should be allowed an opportunity to earn on the equity financed portion of their operations.

Q3. What is the purpose of your rebuttal testimony?

A3. I have been asked by the Applicants to respond to the Direct Testimony of Ms. Lois J. Hubert ("Hubert Direct") on behalf of Staff of the Public Service Commission of Wisconsin and to the Direct Testimony of Mr. Richard A. Baudino ("Baudino Direct") on behalf of the Wisconsin Industrial Energy Group, Inc. regarding their recommendations for the allowed return on equity for the Applicants.

Q4. What rates of return on equity do the Hubert Direct and Baudino Direct recommend?

A4. The Baudino Direct addresses only the return for WEPCO and recommends a return of 9.70 percent on a capital structure with a reduced percentage of equity of 53.5 percent compared to the filed percentage of 56.14 percent. Both capital structures include short-term debt.[1] The Hubert Direct recommends an equity return of 10.75 percent for both of the Applicants, but reduces the equity percentage in the regulatory capital structure for both Applicants. The Hubert Direct recommends a relatively small reduction to a 54.36 equity percentage for WEPCO but recommends a major reduction for WG to 44.10

[1] The Baudino Direct relies on the testimony of Mr. Lane Kollen ("Kollen Direct") for the recommended capital structure for WEPCO. See Kollen Direct, Exhibit LK-10, pp. 1-2.

percent compared to the filed percentage of 52.16 percent.[2] The recommended reduction in both equity return and equity thickness represents a substantial decrease in earnings for the Applicants, but particularly for WG. Although each testimony recognizes the importance of considering financial risk, neither actually considers differences in financial risk between the sample companies and the regulated companies. Furthermore, there is no consideration of the change in financial risk from a change in the recommended regulatory capital structures. Each testimony expresses concern with the ATWACC approach to making this adjustment due to a misunderstanding of the method; however, there are other well recognized methodologies that each witness could have utilized to try to account for the financial risk they note as important. Failure to recognize financial risk represents a material error in their approaches.

II. CAPITAL STRUCTURE AND THE COST OF EQUITY

Q5. What does this section of your rebuttal testimony address?

A5. This section describes the primary source of the differences in the recommended return on equity in the Vilbert Direct compared to the recommendations of the Hubert Direct and the Baudino Direct. Although there are differences in the implementation of the two standard estimation models, the primary source of the differences lies in the recognition of differences in financial risk among the sample companies and between the samples and the regulated companies. The Vilbert Direct uses the after-tax weighted-average cost of capital ("ATWACC") approach to capture the differences in financial risk, but both the Hubert Direct and the Baudino Direct ignore financial risk in arriving at their recommended return on equity. In addition, in their critique of the ATWACC method both of the testimonies demonstrate a fundamental a misunderstanding of the ATWACC approach. If the Hubert Direct and Baudino Direct had considered financial risk, their recommended returns on equity would have been very similar to the Vilbert Direct's 11.2 percent recommendation. The section concludes with a comparison of the off-balance sheet debt of the companies in the electric sample compared to the imputed debt of WEPCO, a fair point raised in the Hubert direct. However, computed on a comparable

[2] See Hubert Direct, Exhibit LJH-1, Schedule 1, pp. 1-2.

basis, the average percentage of off-balance sheet debt of the electric sample is approximately the same as for WEPCO, resulting in almost no change to the estimates and no change to my recommendation.

A. The Use of the ATWACC Approach

Q6. Is it appropriate to estimate the cost of equity for the sample companies using market data?

A6. Yes. The Hubert Direct, the Baudino Direct and the Vilbert Direct all estimate the cost of equity for the sample companies using market information. The alternative is to rely on accounting information on the return on equity realized on book value assets as is done in the comparable earnings approach. The Dividend Valuation Model ("DCF" model) and the risk positioning model rely upon market information, and the cost of equity estimates derived from those estimation models reflect the business risk and financial risk of the sample companies at their *market value* capital structures. The returns on equity recommended by both the Hubert Direct and the Baudino Direct are derived from these models, but the Baudino Direct completely ignores any differences in financial risk. The Hubert Direct acknowledges financial risk resulting from off-balance sheet debt, but it also ignores differences in financial risk among the sample companies and the regulated companies. This omission is contrary to basic financial theory and real world economics. In addition, both testimonies demonstrate a misunderstanding of the ATWACC approach and its adjustment for financial risk.

Q7. Please review the ATWACC approach.

A7. The fundamental premise of the ATWACC approach is that the risk of the assets of a company is divided between the debt holders and equity holders, i.e., the company's investors.[3] The more debt that is used in the company's capital structure, the more risk the equity holders bear because debt holders are paid first, but the total risk of the assets is unchanged. The additional risk to equity holders from the use of debt is called financial risk. Both the Hubert Direct and the Baudino Direct acknowledge financial

[3] Preferred equity is ignored for simplicity, but the principles do not change with the addition of preferred stock to the capital structure.

risk,[4] but neither seems to acknowledge that the cost of equity estimated by both the DCF model and the risk positioning model reflects not only each sample company's level of business risk but also its level of financial risk. Two otherwise identical companies but with different market value capital structures would have different estimates of the cost of equity (estimation errors aside) because of differences in financial risk, but their overall cost of capital, i.e., their ATWACCs would be the same. This is why the ATWACC approach is the best way of approaching the cost of equity estimation problem – it is the only cost common to all companies of similar business risk and can therefore provide the only reliable anchor point. Moreover, a company's financial risk depends upon its market value capital structure not its book value capital structure.[5] The ATWACC approach estimates the overall cost of capital for the sample company's assets as the weighted-average of the market costs of debt and equity where the weights are the percentages of debt and equity in the market value capital structure.

Q8. The Hubert Direct claims that the purpose of the ATWACC is "to maintain current earnings/market-to-book ratios", and the Baudino Direct claims that it should not be used to "prop up high market-to-book ratios".[6] Are these statements an accurate assessment of the ATWACC approach?

A8. No. Both the Hubert Direct and the Baudino Direct focus on the claim that the ATWACC approach is an attempt to maintain a particular ratio of the market value of equity to the book value of equity (the "market-to-book value"), but this is incorrect.[7] The market-to-book value is irrelevant to the ATWACC approach. These statements represent a fundamental misunderstanding of the ATWACC concept.

Q9. Please explain why the market-to-book ratio is irrelevant to the ATWACC approach?

A9. Note that in the calculation of the ATWACC book values are not considered; therefore, there is no way that it can anchor the market-to-book ratio. What matters is the

[4] Hubert Direct pp. 31-32; Baudino Direct p. 9.

[5] This is all well accepted financial theory. See, for example, Richard A. Brealey, Stewart C. Myers, and Franklin Allen, *Principles of Corporate Finance*, New York: McGraw-Hill/Irwin 8th ed. (2006) pp. 503-06.

[6] Hubert Direct, p. 36, and Baudino Direct, p. 32.

[7] Hubert Direct pp. 32-33; Baudino Direct pp. 30-31.

percentage of the market value capital structure that is equity relative to the percentage that is debt. In particular, the market-to-book ratio can be anything.

Q10. Please explain the source of the misunderstanding of the ATWACC approach.

A10. The source of the misunderstanding is that the ATWACC is a *rate of return* not a dollar amount of return. The flaw in reasoning can be illustrated in the following simplified example. Suppose that the cost of equity estimated using the DCF or the risk positioning method is 10 percent for a regulated company with a market value capital structure with 66.6 percent equity and 33.3 percent debt. (See Step 1 in Figure 1 below.) Suppose that the book value capital structure is 50 percent equity and 50 percent debt and that the ATWACC adjusted return on equity is 12.1 percent. (See Step 2 in Figure 1 below.) Does this mean that if the Commission allows a 12.1 percent return on equity that the return on the market value of equity will be 12.1 percent? The answer, of course, is no. The reason is that the estimated return on equity is applied to the *book value* of equity in the rate base not the market value of equity. In this example, the market-to-book ratio is 2.0, the market return on equity would be about 6 percent, ½ of the allowed return on the equity financed portion of the rate base, which would likely be less than the company's current market cost of debt. (See Step 3 in Figure 1 below.)

Figure 1: Example of ATWACC approach, and the resulting return on the market value of equity.

Step 1: Compute ATWACC using market values

	Market Values		Return	Tax Rate	Wt. Average
Equity	1000	67%	10.0%		0.067
Debt	500	33%	6.0%	40%	0.012
	1500	100%		ATWACC	**0.079**

Step 2: Using book value capital structure, compute allowed return on equity that yields the ATWACC determined in Step 1

	Book Values		Return	Tax Rate	Wt. Average
Equity	500	50%	12.1%		0.061
Debt	500	50%	6.0%	40%	0.018
	1000	100%		ATWACC	**0.079**

Step 3: Implied allowed equity return on market value of equity

	Dollar amount	Rate of Return
Equity Return	60.7	**6.07%**

Q11. If the allowed return on equity is 12 percent instead of 10 percent are you saying that this will or will not maintain the current market-to-book ratio?

A11. The ATWACC approach does not say anything about this. Instead, the ATWACC approach simply says that the estimated return on investments of comparable business risk to the regulated company is equal to the ATWACC. Therefore the regulated assets should be allowed a *rate of return* equal to the ATWACC on the *book value* rate base. Moreover, the dollar amount of equity return is unlikely to justify the market-to-book ratio of 2.0 in the example.

Q12. But isn't a market-to-book ratio of 2.0 prima facie evidence that the allowed return on equity has been too high?

A12. No, but it does say that we don't have a complete theory of the determination of security prices, a point that Hubert Direct acknowledges in the quotation on p. 43 from Professor Andrei Shleifer:

> Despite considerable progress, our knowledge of determination of security prices remains limited. Although we may reject the null hypothesis of market efficiency with more confidence than before, we still know relatively little about such key determinants of prices as expectations about fundamentals, discount rates, and simple movements of demand. Behavioral finance, and the finance of the determination of valuations more generally, has many years to grow.

We simply don't have complete explanations of the level of stock prices in the market.

Q13. The Baudino Direct seems to imply that the ATWACC method is incompatible with the use of a book value rate base.[8] Is this true?

A13. No. The use of book value rate base is perfectly consistent with the use of a rate of return calculated from market data using the ATWACC method. The book value rate base is merely a historical record of the amount of assets purchased by investors to provide service to customers. All rate-of-return analysts estimate a market cost of capital to apply to that investment, and as noted above, all three testimonies use market data to estimate the cost of equity for the sample companies. The only difference is that the Vilbert

[8] Baudino Direct, p. 30-31.

Direct calculates the overall market rate of return on assets and applies that overall rate of return to the rate base. Because the regulated capital structure differs from the market value capital structures of the sample companies, the allowed return on equity must be adjusted so that the weighted-average cost of capital used to set rates is equal to the market-determined overall cost of capital from the sample of companies with comparable business risk.

B. Off-Balance Sheet Debt

Q14. The Hubert Direct notes that the Vilbert Direct did not attempt to capture the off balance sheet debt of the electric sample[9] used to estimate WEPCO's cost of capital. How do you respond?

A14. The Hubert Direct's point is well taken. It would be inconsistent to consider the imputed debt of WEPCO[10] without also having considered the imputed debt of the sample companies; however, three points are relevant here.

First, the Vilbert Direct's recommendation for the allowed return on equity for WEPCO is based upon the regulatory capital structure of the Wisconsin Electric, not the financial capital structure including imputed debt. If imputed debt had been considered in developing the return on equity recommendation, the return on equity would have been higher. Second, neglecting to consider the imputed debt of the sample companies would be of greatest concern if the relative amount of imputed debt of the sample companies was substantially greater than the amount of imputed debt of WEPCO. I have estimated the percentages of imputed debt of the companies in the electric sample, and on average it is not different than the amount of imputed debt estimated for WEPCO. Finally, if imputed debt had been considered in estimating the electric sample's ATWACC as well as for developing the return on equity recommendation for WEPCO, the net change would nearly be zero. The estimated ATWACCs for the sample would be lower, but the increased financial risk inherent in the financial capital structure, instead of the regulatory capital structure, would increase the return on equity for WEPCO. On balance, the return

[9] Hubert Direct, p. 32.

on equity recommended in the Vilbert Direct would not change if all of WEPCO's off-balance sheet debt were considered. This point is illustrated in the tables attached to this rebuttal (labeled Table No. MJV-R1 to Table No. MJV-R12) which are modifications of the original tables for the electric sample in the Vilbert Direct.

1. The Sample's Imputed Debt

Q15. What does this section of your rebuttal testimony address?

A15. This section discusses the calculation of the imputed debt of the companies in the Vilbert Direct's electric sample. The magnitude of the sample companies' off-balance sheet obligations stemming from operating leases, power purchase agreements, unfunded pension obligations, and possibly other off-balance sheet obligations is determined by reviewing the companies' annual 10-K filings.

Q16. Please summarize the issues involved with imputed debt.

A16. The financial community, rating agencies, as well as the Public Service Commission of Wisconsin recognize that there are risks involved in entering into Power Purchase Agreements ("PPA").[11] This means that signing a long-term PPA increases the financial risk of the purchasing utility commensurate with the size and length of the fixed-cost obligations in the contract. The financial risk inherent in signing a long-term PPA is measured by the credit rating agencies and is known as "imputed debt" or "debt equivalence".[12] For example, Standard & Poor's (S&P), has clearly stated its view for many years that long-term PPAs impose financial risk on the utility and has developed

---

[10] WG has no off-balance sheet debt in its filed financial capital structure so this section focuses only on WEPCO.

[11] For example, S&P's, Fuel and Purchased Power Cost Recovery in the Wake of Volatile Gas and Power Markets – U.S. Utilities to Watch, Report, March 22, 2006 and S&P, "Request For Comments: Imputing Debt To Purchased Power Obligations," November 1, 2006.

[12] Credit rating agencies have generally treated long-term PPA contracts differently from short-term power contracts. In the past, credit rating agencies did not believe that short-term contracts (in particular those signed in retail access states for Provider of Last Resort ("POLR") service, which are generally three-month to three-year contracts and are rebid periodically to keep prices closer to the spot market), carried the same negative financial impact as a long-term PPAs. However, S&P recently announced that it is will impute debt from most such "evergreen" contracts going forward. See, *Imputed Debt Calculation for U.S. Utilities' Power Purchase Agreements*, S&P RatingsDirect, March 30, 2007. S&P excludes PPAs in which the utility merely acts as a conduit for delivery of power. See *Standard & Poor's Encyclopedia Of Analytical Adjustments for Corporate Entities*, July 9, 2007 p. 24.

and publicized a standard procedure for calculating imputed debt and its impact on the financial ratios used to measure a utility's creditworthiness.[13] In the electric industry, major commitments for which S&P imputes debt are purchased power contracts, operating leases, and the unfunded portion of post-retirement obligations. These are the focus of my approximation of the amount of imputed debt.

2. Standard and Poor's Imputed Debt Methodology

Q17. Please describe your estimation of imputed debt for the sample companies.

A17. For each sample company in the electric sample, I estimate the imputed debt associated with operating leases, PPAs, unfunded pension obligations and nuclear decommissioning trusts (if applicable). In doing so, I attempted to follow the procedures relied upon by S&P as precisely as possible given the data available. For operating leases, S&P calculates the present value of future minimum lease payments using the utility's average embedded interest rates. Using the disclosed information about the lease payments over the next five years, I estimated the present value of operating lease payments using a discount rate that corresponds to the bond yield on bonds of comparable rating to that of the utility.[14] For PPAs, S&P calculates the present value of the fixed (capacity) payments of the PPA using the utility's embedded cost of debt. If capacity payments are not specified, S&P usually assumes that 50% of the total payment is for capacity.[15] Lastly, S&P applies a so-called risk-factor to the present value which is a company specific measure that takes the company's specific recovery-risks into account. The benchmark is 25% for capacity payments that are recovered through fuel adjustment clauses.[16] I

[13] Fitch Ratings and Moody's have been less forthcoming with specifics regarding their treatment of imputed debt but both credit agencies acknowledge that it may impact creditworthiness. See, for example, FitchRatings, *Corporate Finance*, "Operating Leases: Updated Implications for Lessees," *Credit*, December 20, 2006.

[14] Note that capital leases are recognized on companies' balance sheet and included in the long-term debt amount reported in Table No. MJV-3. However, operating leases are not part of the balance sheet and not included in Table No. MJV-3. In calculating credit ratios, S&P includes the imputed debt as a liability and as an asset (S&P also makes adjustments to income).

[15] "Imputed Debt Calculations for U.S. Utilities' Power Purchase Agreements," *Standard & Poor's*, March 30, 2007.

[16] See "Imputed Debt Calculations for U.S. Utilities' Power Purchase Agreements," *Standard & Poor's*, March 30, 2007 and "Request for Comments: Imputing Debt to Purchased Power Obligations," *Standard & Poor's,* November 1, 2006.

followed this approach using the four year disclosure in the sample companies' 10-Ks to estimate the magnitude of their PPAs.[17] As for operating leases, the discount rate was set equal to the yield on a bond index of the same rating as that the target company. As a benchmark, the capacity payment was assumed to equal 50% of the total PPA payment and the risk-factor was set equal to 25%. S&P also includes pension obligations in its calculation. Specifically, S&P includes the postretirement benefit obligation as a long-term liability and the fair value of the plan assets as part of equity.[18] To implement this, I included the difference between the obligation and the funding as a long-term debt when the amount was negative (e.g., an unfunded plan) and as part of assets when the fair value was larger than the benefit obligation.[19] Finally, I included any nuclear decommissioning trust obligations as a long-term obligation in the determination of imputed debt. The result of these adjustments is that the electric sample's debt percentage increases from an average of 41% to about 44%.[20]

Q18. What is the amount of imputed debt for Wisconsin Electric?

A18. As of May 2007, Wisconsin Electric estimated imputed debt of $308 million.[21] This amount included the Point Beach PPA but not any unfunded pension obligations. The amount of imputed debt determined by the rating agencies could change if the "risk factor" used by S&P were changed from the 25 percent value used in the current estimate to a 40 percent value.[22] As of year-end, Wisconsin Electric reported approximately $294.6 million in unfunded pension obligations.[23]

---

[17] NSTAR has significant "buy-out obligations" which are related to former power purchase agreements. Therefore, these obligations were treated as if they were power purchase obligations. According to NSTAR 2006 10-K p. 48, these "payment obligations do not affect NSTAR's overall cash flow."

[18] "Credit FAQ: S&P Introduces Reconciliation Tables to Show Analytical Adjustments to Global Utilities' Financial Statements," *Standard & Poor's*, October 11, 2006.

[19] The only company for which the benefit obligation is lower than the fair value of the plan's assets was Southern Company.

[20] See Table No. MJV-R4 compared to Table No. MJV-4 in the Vilbert Direct.

[21] See Workpaper #4 to Table No. MJV-4.

[22] The risk factor is a rating used by S&P to measure the likelihood of a company's full recovery of the PPA payments.

[23] Wisconsin Electric 2006 10-K p. 93.

Q19. How did you use this information?

A19. Having estimated the magnitude of the imputed debt among the sample companies, I adjusted the sample companies' market value capital structure. In doing so, I rely on four years of data rather than five years as was done in the Vilbert Direct. This choice is necessary to avoid potential inconsistencies with data reported before and after January 1, 2003 due to changes in reporting requirements. To approximate the impact of off-balance sheet debt and assets, I added the estimated imputed debt to the market value of debt **and** added operating leases as well as pension funding in excess of obligations to the company's assets. The market value of equity was not changed as the companies' stock price is already expected to reflect all publicly available information. Having determined the impact of the imputed debt on the companies' capital structures, I estimated the sample's ATWACC using the revised capital structures. I then determined the cost of equity that would result from relying on the sample's revised ATWACC including imputed debt and Wisconsin Electric's regulatory capital structure including imputed debt (as reported in Workpaper #4 to Table No. MJV-4).

Q20. What were the results of this analysis?

A20. Taking the imputed debt of the sample companies and Wisconsin Electric into account does not substantially change the cost of equity estimate. If Wisconsin Electric's unfunded pension liability is considered (as it is for the sample companies), the return on equity estimates from the sample would increase slightly (about 3 bps), but this is not enough to change my recommended return on equity for Wisconsin Electric. As shown in Table 1 below, the resulting cost of equity estimates from the sample are indistinguishable from those provided in the Vilbert Direct.[24]

[24] See Table 3, p. 30 of the Vilbert Direct.

III. PROBLEMS WITH STAFF'S AND WIEG'S ESTIMATION METHODOLOGY

Q21. What does this section of your rebuttal address?

A21. This section addresses issues with the implementation of the DCF model and the risk positioning model by the Hubert Direct and the Baudino Direct.

A. ISSUES WITH IMPLEMENTING THE DCF MODEL

Q22. Please start with the DCF model. What are your criticisms of the approaches used by the Hubert Direct and the Baudino Direct?

A22. My criticisms center on the importance of the earnings growth rate forecasts and the estimate of the dividend yield in the model.

1. Problems with Estimating the Dividend Growth Rate

Q23. Please review the underlying theory of the DCF model.

A23. The DCF model assumes that that the price of a stock is equal to the present value of all future dividends discounted at a single cost of capital. The simple DCF model illustrated in equation (6) of the Vilbert Direct and reproduced as Equation (1) below assumes that dividends grow a constant rate literally forever. The same formula is on p. 11 of the

Baudino Direct and is discussed on p. 24 of the Hubert Direct.[25] As discussed in the Vilbert Direct[26], the simple DCF model relies on very strong assumptions to arrive at the very simple formula. In particular, not only must dividends grow as a constant rate forever, so must earnings, stock prices, and book values, because that is the basis of the development of the model. The DCF model is conceptually sound if its assumptions are met, but frequently the assumptions are not met and this presents a major problem for analysts who rely on the DCF model.

$$P = \frac{D_1}{(1+k)} + \frac{D_2}{(1+k)^2} + \frac{D_3}{(1+k)^3} + \cdots + \frac{D_T}{(1+k)^T} \quad (1)$$

Q24. The Baudino Direct criticizes the Vilbert Direct's implementation of the DCF model because it relied exclusively on earnings growth forecasts and not on dividend growth rate forecasts. How do you respond?

A24. Dividends are the quantity in the model, but dividends are paid from earnings. Therefore earnings are the more fundamental input. In addition, the Baudino Direct's criticism is misplaced, because a difference in growth rates between earnings and dividends is a violation of the assumptions underlying the model. The two growth rates may vary for short periods, but over the long term horizon of the model, they must grow at the same rate, as is acknowledged in the Hubert Direct.[27] If dividends and earnings are expected to grow at different rates for extended periods of time, it would be appropriate to question the applicability of the model to the industry in question.

Q25. Both the Vilbert Direct and the Hubert Direct utilize a two-stage DCF model. Doesn't such an approach solve the problem with the variation in short-term dividend growth rates?

A25. No. Both testimonies *assume* a pattern of growth rates in earnings (and dividends) for the period beyond year 6 because there is no other alternative. The longest forecast period

[25] There is an error is the presentation of the formula on p. 24 of the Hubert Direct. The model is developed on the assumption that the most recent dividend has just been paid. In other words, D_0 should be removed from the formula for the current price, P_0.

[26] Vilbert Direct, p. 22.

[27] Hubert Direct, p. 25.

for earnings growth rates is 5 years, so all growth rate estimates beyond year 5 are by necessity based upon assumptions; however, the cost-of-equity estimates depend critically upon the assumed growth in earnings (and dividends). In general, an increase (decrease) in the assumed growth rate results in a comparable increase (decrease) in the estimated cost of equity. In other words, if the growth rate is assumed to be five percent instead of four percent, the cost of equity will increase by slightly more than one percentage point because the assumed growth rate affects the dividend yield as well.

Q26. The Baudino Direct does not use a two-stage DCF model. How does the Baudino Direct deal with the issue of long-term growth rates?

A26. The Baudino Direct says that the DCF model "could easily handle varying growth rates **if we knew what they were** [emphasis added]."[28] Of course, the problem is that we don't know what the growth rates truly are. As a result, the Baudino Direct is forced to analyze the individual company earnings forecasts and make judgments as to which estimate seems to be too high or too low to be sustainable. Companies with growth rates "judged" by the witness to be inappropriate are eliminated from the Baudino Direct's sample.[29]

Q27. How does the lack of information on long-term growth rates affect the Hubert Direct DCF estimates?

A27. The Hubert Direct assumes that the growth in earnings and dividends is 2.5 percent, equal to a forecast of inflation, beginning either five or 10 years in the future. If that assumed growth rate were any other value, the estimated cost of equity would be higher or lower by approximately the change in the forecast growth rate. There is no information on the growth rate of earnings after year five so not only is this estimate arbitrary, but it is also critical to the outcome of the model. For example, changing the assumed long-term growth rate from 2.5 to 5.5 percent increases the DCF estimates from 7.12 to 7.71 percent to 9.66 to 9.74 percent for the Hubert Direct's energy utilities sample.[30]

---

[28] Baudino Direct, p. 11.

[29] Baudino Direct, p. 13.

[30] Hubert Direct, p. 26.

Q28. Doesn't the Vilbert Direct use a terminal growth in earnings in the DCF model equal to the forecast growth rate of GDP?

A28. Yes, but this is also an assumption. Alternative assumptions could be justified precisely because there is no information on earnings and dividend growth rates beyond year 5. This lack of growth rate information is one of the biggest weaknesses of the DCF model. As noted in the Vilbert Direct, the DCF model is only reliable for an industry in stable conditions because only then are the five-year growth rates likely to be equal to the long-term growth rates.

In addition, the use of the forecast growth in GDP as a terminal growth rate in the DCF model is an attempt, in part, to address the concern raised by the Baudino Direct that earnings forecasts may be overstated.[31] The use of the GDP growth rate moderates the effect of either high or low short-term (5-year) analysts' earnings forecasts.

Q29. Please summarize your criticisms of estimating the growth rate for use in the DCF model.

A29. The results of the DCF model depend critically on the forecast of dividend growth rates, but analysts generally have no information on the forecast growth rates of earnings or dividends for periods longer than five years. All analysts are forced to assume a pattern of dividend growth for years 6 through infinity for the model, but those assumptions determine the results. As a consequence, the DCF model is unreliable unless it is being applied to an industry that is in a stable growth path for the foreseeable future. I do not believe that either the regulated electric utility industry or the gas LDC industry could currently be characterized as stable. As a result, the DCF estimates for these two industries are not reliable at this time.

Q30. Baudino Direct asserts that the regulated electric industry is "entering a more stable, less risky environment than it experienced during the last few years."[32] Do you agree that this is an accurate assessment of the state of the industry?

A30. No. The Baudino Direct quotes the August 31, 2007 *Value Line Investment Survey* which says that "electric utilities are traditionally safe-harbor investments".[33] Regulated

[31] Baudino Direct, p. 38.

[32] Baudino Direct, p. 6. The same idea is repeated on p. 26 and p. 34 of the Baudino Direct.

companies are of lower risk compared to the average company in the market, but that does not imply that the industry is entering a period of stability going forward. For example, the Baudino Direct acknowledges the recent fall in electric utility stock prices,[34] but does not seem to believe that this may be a potential sign of higher risks in the future.

There are several reasons why uncertainty about the industry's future is not likely to have decreased as the Baudino Direct assumes. First, the September 28, 2007 *Value Line* report cited by Baudino Direct points to the need for substantial investment in generation and transmission,[35] a point also mentioned in several reports commissioned by the *Edison Electric Institute.*[36,37] The prices of fossil fuels have increased dramatically over the last few years. Construction prices have also recently increased rapidly, and uncertainties exist about how the rise in prices will affect the infrastructure investment strategy:

> However, rising construction costs will put additional upward pressure on retail rates over time, and may alter the pace and composition of investments going forward. The overall impact on the industry and on customers, however, will be borne out in various ways, depending on how utilities, markets and regulators respond to these cost increases.[38]

According to the most recent *Value Line* report,[39] Wisconsin Energy itself has "[a] lot of generating projects under way," including generating plants, environmental upgrades, transmission spending, and a wind project. Full recovery of rapidly increasing costs is always uncertain for a regulated company.

Second, public concern with environmental sustainability and the need for renewable sources of energy has led to the adoption in many states, including Wisconsin, of

---

[33] Baudino Direct, p. 5, line 20.

[34] Baudino Direct, pp. 5-6.

[35] Baudino Direct, p. 6, line 12.

[38] *Ibid.*, p. 31.

[39] Wisconsin Energy's *Value Line* sheet as of September 28, 2007.

renewable generation requirements.[40] It seems certain that environmental concerns will increase in the future, but the impact of these concerns on renewable energy requirements and restrictions on green house gases is uncertain, and this uncertainty is a clear source of risk for electric utility investors. For example, at the Federal level, the House passed a bill this summer proposing a 15 percent renewable energy requirement by 2020, while an earlier Senate bill on energy did not include a similar requirement.[41] For Wisconsin Energy the "construction of the coal plants has prompted environmental challenges that have increased the company's costs by $50 million - $55 million."[42] Clearly, environmental issues are an important source of uncertainty about future costs and regulation, and increase the risk of regulated electric utilities.

Q31. Please summarize your conclusions regarding the stability of the electric utility industry at this time.

A31. The future structure of the electric utility industry is far from certain. The industry faces the need for substantial capital investment going forward to meet the challenges of new environmental and safety standards as well as the need for conservation. Acquiring the capital necessary for the required investments will require a supportive regulatory environment including an adequate return on equity. These challenges and the resulting uncertainty mean that the industry is not in the stable, low risk environment envisioned in the Baudino Direct and which is required for the reliable estimation of cost of equity using the DCF model.

2. Inconsistency in Estimating the Dividend Yield

Q32. What are your comments on the estimation of the dividend yield?

A32. The calculation of the dividend yield in the Baudino Direct with reference to a 6-month average price destroys one of the primary advantages of the DCF model in that it is

---

[40] Wisconsin Statutes, Chapter 196, Section 378, available at http://nxt.legis.state.wi.us/nxt/gateway.dll?f=templates&fn=default.htm&vid=WI:Default&d=stats&jd=top.

[41] These pieces of legislation have been widely reported in the national press. For a specific reference, see *Edison Electric Institute* press release of August 4, 2007, available at http://www.eei.org/newsroom/press_releases/070804.htm.

[42] Wisconsin Energy *Value Line* sheet as of September 28, 2007.

forward looking model.[43] The simple DCF model shown below says that the return is equal to the dividend yield plus expected growth in dividends (and earnings):[44]

$$\begin{aligned} k &= \frac{D_1}{P} + g \\ &= \frac{D_0 \times (1+g)}{P} + g \end{aligned} \qquad (2)$$

The current market price reflects investors' expectation regarding changes in interest rates, expected growth rates for the company and developments in the economy as a whole. Stock prices from over a period of 6 months include the payment of at least two quarterly dividends and reflect stale and out of date information. For example, the Baudino Direct recognizes that the Federal Reserve cut the Federal Funds rate by 50 basis points ("bps") on September 18, 2007.[45] Stock prices from April to August do not reflect this development or any other current development in the economy, but current forecast growth rates do consider this and other economic developments. Although it is important to guard against unusual fluctuations in stock prices, as the Vilbert Direct has done by averaging the price over the three week period prior to the release of the earnings growth forecasts, use of a 6-month average is unjustified and may bias the results.

Q33. What is the effect of relying on a 6-month average stock price for the Baudino Direct's DCF results?

A33. Exhibit 1, Schedule 3, page 2 of 3 displays the results of using a 6-month average dividend yield. Because dividend yields generally increased from April through about August 2007 before declining slightly in September, the 6-month average dividend yield underestimates the dividend yield for September. Note that whether the technique underestimates or overestimates the dividend yield in this particular instance is not the point. Rather the point is that the method seriously weakens one the primary advantages of the DCF model in that it is capable of rapidly reflecting changing market conditions.

[43] The Hubert Direct is not specific as to how the dividend yield for the sample companies was calculated.

[44] This is equation (6) from the Vilbert Direct.

[45] Baudino Direct, p. 4.

Q34. The Baudino Direct also criticizes the Vilbert Direct for use of quarterly compounding asserting that it is already captured in the market price?[46] What is your response?

A34. The Baudino Direct is simply incorrect on this point. The criticism assumes that the Vilbert Direct annualizes the quarterly dividend (multiplies by 4) before compounding, but this is incorrect. The Vilbert Direct uses the most recent quarterly dividend and the quarterly forecast growth rate in earnings to estimate the required quarterly return on equity. The quarterly return on equity is then annualized to produce the cost of equity estimate on an annual basis. This approach is precisely how the DCF model, upon which both testimonies rely, is developed as shown in Equation (1) above. It would be an underestimate of the cost of equity estimate not to acknowledge the quarterly payment of dividends.

Q35. Do you have any other comments on the Baudino Direct's implementation of the DCF model?

A35. Yes. The Baudino Direct provides an alternative estimate of the DCF growth rate called the sustainable growth rate, but the formula used ignores the growth in earnings that results from the issuance of additional stock at a price greater than its book value. Ignoring this source of growth biases the growth estimates downward. The alternative to the equation on p. 16 of the Baudino Direct is shown below in Equation 3, where growth from new share issues depends on the percentage of new shares being issued, *s*, and the equity accretion ratio $v = \left[1 - \frac{1}{Market\text{-}to\text{-}Book\ Ratio}\right]$. Together, the implied sustainable growth rate is given as shown in Equation **(3)**:

$$g = br + sv \qquad \textbf{(3)}$$

Q36. Please summarize your comments on the DCF model

A36. Both the Hubert Direct and the Baudino Direct seem to believe that the DCF model provides more reliable estimates of the cost of capital for the sample companies than the risk positioning model does at this time, but that belief is highly debatable at best. The

[46] Baudino Direct, p. 40.

future development of the electric industry is uncertain at this time, and the natural gas industry must deal with rapidly increasing commodity prices and decreasing average consumption so the stable conditions necessary for the reliable implementation of the DCF model are not present at this time for either industry. Consider the following examples from both testimonies. Each is concerned with forecast growth rates that are either too high or too low to be sustainable and eliminate companies from the sample for that reason alone. As noted above, all DCF models require a rate of dividend growth for the years after year five, but there is no generally available information on these growth rates so all analysts must assume a rate. Unfortunately, that rate is critical to the DCF estimate of the cost of equity. Finally, it is not unusual for a company to have a DCF cost of equity estimate less than its own cost of debt, an outcome contrary to any reasonable risk-return tradeoff. As noted in the Vilbert Direct,[47] the DCF model can be a useful model if its assumptions are fully met, but those assumptions are so strong (and have such a large effect on the estimated cost of equity) that it is unusual for the conditions necessary for the completely reliable implementation of the model to be present.

B. Issues with the Implementation of the Risk Positioning Model

Q37. How does the Hubert Direct use the risk positioning model?

A37. The Hubert Direct acknowledges that it does not use the risk positioning model to forecast the required cost of capital, but instead uses historical averages of the spread between past interest rates and past allowed rates of return on equity for the Companies as a measure of the reasonableness of the recommended rates of return in this proceeding.[48]

Q38. Is the reliance on the historical spread between past allowed rates of return and past interest rates reasonable?

A38. No. First, reliance on the allowed rate of return for the rate regulated companies leads to circularity in the rate making process. This is especially true when the allowed rates of

[47] Vilbert Direct, p. 23.

[48] Hubert Direct, pp. 27-29.

return pertain to the companies for which rates are being set.[49] Second, the Hubert Direct includes data from five years: 1989, 1991, 1992, 1993, and 2006. This is too few observations to conclude what the interest rate premium should be and especially so because the interest rates relied upon (30-year T-Bond, 10-year T-bond, and AA utility bond yields) have dropped significantly during the period. The 10-year T-bond yield dropped 467 basis points during the period while the corresponding interest rate premium increased 197 basis points.[50] For each interest rate measure, the lowest interest premium measured occurs in 1989 while the highest premium measured occurs in 2006. Third, to the extent that the increase in the allowed interest rate spread for the more recent period represents a recognition of changed circumstances for the Companies, the 1989 interest rate spread would not be representative of those changed circumstances.

Q39. What are the implications of these observations?

A39. There is a danger of circularity in relying on allowed rates of return for utilities for which the Commission is currently setting rates. Moreover, because interest rates as well as other features of the regulatory and economic environment have changed dramatically the more recent 2006 observation is more likely to be in line with today's changed economic and regulatory environment. Relying on the 2006 interest rate spread results in a return on equity estimate of 11.19 to 12.24 percent[51] which is consistent with the estimate in the Vilbert Direct of 10½ to 11½ percent for Wisconsin Electric and 11 to 12 percent for Wisconsin Gas.[52]

Q40. Please turn to the Baudino Direct's implementation of the CAPM. In your judgment, does the Baudino Direct contain a number of incorrect or misleading statements regarding the risk positioning model?

A40. Yes. The Baudino Direct begins by describing the CAPM in a standard and generally correct way, but then makes a series of statements contrary to the Baudino Direct's own

[49] See Roger A. Morin (2006), *New Regulatory Finance*, Public Utilities Reports, Inc., pp. 306-307 for a discussion of circularity.

[50] Hubert Direct, Schedule 8, p. 2.

[51] Hubert Direct, Schedule 8, p. 2.

[52] Vilbert Direct p. 5.

description of the model. I will first list the statements and then describe why the statement is misleading or incorrect. [53]

1. "There is evidence that beta is not the primary factor in determining the risk of a security."
2. "Beta coefficients usually describe only a small amount of total investment risk."
3. "Finally, a considerable amount of judgment must be employed to in determining the risk-free rate and the market return portions of the CAPM equation."

Q41. Please discuss the first statement that there is evidence that beta is not the primary factor in determining the risk of a security.

A41. The statement is true but materially misleading. The Baudino Direct is correct that the CAPM has been challenged with regard to whether beta is the *sole* measure of investment risk for a security. In the alternative models, such as the Fama-French model, beta has been supplemented by other risk factors, but beta retains a central role in explaining expected stock returns.

Q42. What about the second statement?

A42. With regard to the second statement that beta coefficients measure only a small amount of total risk, the statement is also technically correct but also materially misleading. By theory beta only measures the portion of risk that affects a company's expected return. This portion of risk is generally labeled market risk or systematic risk. This is in contrast to the risk that does not affect the cost of capital which is labeled diversifiable risk. Because investors can avoid diversifiable risk, they do not expect to earn a rate of return on such risk. This is the result of standard portfolio theory. Beta does measure only a part of a company's total risk, but importantly it measures only the part that determines the company's cost of capital which is what is required for the model.

Q43. What about the last statement?

A43. Finally, it is a matter of judgment as to how difficult it is to estimate the risk-free interest rate and the market risk premium ("MRP"), but there is a great deal of data to use to estimate both parameters compared to little to no data upon which to forecast the growth rate in the DCF model for the period after year five. Daily data on the current yields of

[53] Each of these statements is from the Baudino Direct, p. 21.

Treasury bills and Treasury notes is widely available so estimating the risk-free interest rate requires only deciding which series to use.

On the other hand, estimating the MRP does indeed require judgment. As noted in the Vilbert Direct, its current value is controversial but reliable data on the realized market premium is also widely available since 1926 through publications such as Ibbotson Associates, *Stock, Bonds, Bills and Inflation, Valuation Edition*, 2007 Yearbook**.** In addition, the academic literature on the magnitude of the MRP is voluminous. These articles and the available data provide the basis upon which to make an informed judgment on the MRP once again in contrast to the lack of information on the long-term growth rate in the DCF model.

1. The Risk-Free Interest Rate

Q44. Please discuss the details of the Baudino Direct's implementation of the CAPM.

A44. I will first discuss the Baudino Direct's estimate of the risk-free interest rate and then the estimate of the MRP.

Q45. How did the Baudino Direct estimate the risk-free interest rate?

A45. The Baudino Direct uses two measures of the risk-free interest rate, the yields on 20-year Treasury bonds and on five-year Treasury notes, but as the Baudino Direct did in the implementation of the DCF model, the Baudino Direct seriously weakens one of the strengths of the model by averaging the yields over a six-month period, April through September 2007. Beta estimates change slowly as would be expected of a measure of a company's systematic risk, but interest rates change much more rapidly. Use of current interest rates results in expected returns from the model that incorporate the most recent developments in the market, but that advantage is damaged by use of interest rates from as long as six months ago.

2. The Market Risk Premium

Q46. What does this section of your rebuttal address?

A46. This section addresses the estimation of the MRP for use in the risk positioning model. The estimate of the MRP is frequently controversial, but some of the controversy stems

from not maintaining consistency of terminology with regard to the findings of the literature. It is important to note whether the MRP is being measured relative to the short-term risk-free interest rate or a long-term risk-free interest rate. It is also important to distinguish between estimates that are based upon the arithmetic mean versus the geometric mean of the data series.

Q47. Is it appropriate to use the geometric mean to estimate the expected return from the risk positioning model?

A47. No. While the geometric mean return is appropriate for consideration of achieved returns over a period of time, it is well established that the geometric mean is not correct for estimating the expected return, especially in a regulatory setting. This is well understood in the broader finance community, and the Baudino Direct is simply in error to raise it here.[54] For example, Ibbotson Associates state

> The equity risk premium data presented in this book are arithmetic average risk premia as opposed to geometric average risk premia. The arithmetic average equity risk premium can be demonstrated to be most appropriate when discounting future cash flows. For use as the expected equity risk premium in either the CAPM or the building block approach, the arithmetic mean or the simple difference of the arithmetic means of stock market returns and riskless rates is the relevant number. This is because both the CAPM and the building block approach are additive models, in which the cost of capital is the sum of its parts. The geometric average is more appropriate for the reporting past performance, since it represents the compound average return.[55]

Similarly, the *New Regulatory Finance* text by Roger A. Morin (2006) argues that

> Only arithmetic means are correct for forecasting purposes and for estimating the cost of capital. There is no theoretical or empirical justification for the use of geometric mean rates of returns as a measure of the appropriate discount rate in computing the cost of capital or in computing present values. There is no dispute in academic circles as to whether the arithmetic or geometric average should be used for purposes of computing the cost of capital.[56]

Finally, the text by Bodie, Kane, and Marcus (2005) states,

---

[54] Baudino Direct, p. 36.

[55] Ibbotson Associates, *Stock, Bonds, Bills and Inflation, Valuation Edition*, 2007 Yearbook, p. 77.

[56] Roger A. Morin (2006), *New Regulatory Finance*, Public Utilities Reports, Inc., pp. 116-117.

> [I]f our focus is on future performance, then the arithmetic average is the statistic of interest because it is an unbiased estimate of the portfolio's expected return (assuming, of course, that the expected return does not change over time). In contrast, because the geometric return over a sample period is always less than the arithmetic mean, it constitutes a downward-biased estimator of the stock's expected return in any future year.[57,58]

Based on the academic and other literature, the geometric average based MRP is not appropriate for estimating cost of capital in a regulatory setting.

Q48. Did the Baudino Direct rely upon the geometric mean in evaluating the results estimating the risk positioning model?

A48. Yes. Consider Exhibit (RAB-1), Schedule 6 in which the Ibbotson historical geometric mean of 5.20 percent and the Ibbotson and Chen geometric mean estimate of 3.55 percent is used in the first column to estimate the cost of equity for WEPCO. As an estimate of the expected return for WEPCO, these estimates are in error and should be disregarded completely.

Q49. How did the Baudino Direct estimate the arithmetic MRP?

A49. The Baudino Direct estimates the market risk premium by applying the DCF model to stocks followed by *Value Line* that pay dividends and then subtracting either the average yield on 20-year Treasury bonds or five-year Treasury notes. The MRP estimates are 7.81 percent and 8.22 percent.[59] This is in contrast the Vilbert Direct's estimate of 6.5 percent for the long-term MRP which illogically the Baudino Direct characterizes as "overstated"[60] even though less than the estimates used in the Baudino Direct.

[57] Zvi Bodie, Alex Kane, and Alan J. Marcus (2005), *Investments*, 6th Edition, McGraw-Hill, p. 865.

[58] See also Richard A. Brealey, Stewart C. Myers, and Franklin Allen (2006), *Principles of Corporate Finance*, 8th Edition, McGraw-Hill, p. 150-151.

[59] Baudino Direct, p. 23.

[60] Baudino Direct, p. 35.

Q50. The Baudino Direct uses two sets of beta estimates, one from *Value Line* and one from First Call/Thompson financial. Were you able to replicate the beta estimates from First Call?

A50. No. Some of the First Call beta estimates are quite low. For example Public Service Enterprise Group has an estimated *Value Line* beta of 0.95 but has a First Call estimated beta of 0.13.[61] I do not have access to First Call, but I was able to use comparable data from Bloomberg to estimate the betas. Bloomberg's 152-week beta estimate for Public Service Enterprise Group is 1.009 very similar to that of *Value Line* over the same 152-week period used in the Baudino Direct. This result leads me to believe that the First Call estimate for Public Service Enterprise Group is an error, so I also estimated the betas for the rest of the sample. Over the 152-week period ending September 28, 2007, the Bloomberg sample average beta estimate is 0.77 unadjusted and 0.84 adjusted compared to 0.49 unadjusted average sample estimate from First Call. Note that the Bloomberg sample average estimate is very similar to the *Value Line* sample average estimate reported in Schedule 5 of the Baudino Direct.

Q51. What is your conclusion from the results of the risk positioning models?

A51. A simple average of the estimates relying on the arithmetic mean MRP is greater than 10 percent even if the First Call betas are assumed to be correct. If the Bloomberg estimates betas are substituted for the First Call betas, the results would be similar to those from *Value Line*, with a resulting range of values in Schedule 5 of 11.49 percent to 10.28 percent. These estimates are substantially higher than the 9.70 percent recommended by the Baudino Direct.

C. Misuse of S&P Rating Information

Q52. What does this section of your rebuttal testimony address?

A52. This section addresses the misuse of the S&P business risk profile rankings and the misuse of a subset of the metrics used by the rating agencies to determine a company's credit rating as justification for reducing the regulatory equity thickness of WG.

[61] Baudino Direct, Schedule 5.

1. S&P Business Risk

Q53. The Hubert Direct asserts that differences in the S&P business risk profile of the companies included in the Vilbert Direct's samples demonstrated that the sample companies are not of comparable business risk to WEPCO and WG.[62] Is this correct?

A53. No. The S&P business risk profile is a *qualitative* index of business characteristics, as described, for example, in a June 2007 S&P Commentary Report:

> To determine a utility's business profile, Standard & Poor's analyzes the following **qualitative** business or operating characteristics typical of a utility: markets and service area economy; competitive position; fuel and power supply; operations; asset concentration; regulation; and management (emphasis added).[63]

In its 2006 Corporate Ratings Criteria, the rating agency lists the following factors as underlying the business risk rating: "country risk, industry characteristics, company position, product portfolio/marketing, technology, cost efficiency, strategic and operational management competence, [and] profitability/peer group comparison."[64]

Nowhere in the documentation does S&P state or imply that the business risk profile is meant to measure, or can be interpreted as measuring, the systematic risk of a company's equity. S&P business risk profile ratings are developed for the purpose of evaluating a company's credit risk, i.e. the likelihood that it will repay its debt, and as such incorporate factors that do not have an impact on the expected return on equity. The proof of this is that the business risk profile is used to help characterize the company's financial ratios as being consistent with a particular bond rating.

In particular, the business risk rating considers some characteristics of the company that, while a source of total risk, are diversifiable and therefore do not affect the expected return on equity (e.g. management strategy, competitive position etc.). As is well

---

[62] Hubert Direct, pp. 37-38.

[63] "U.S. Utility and Power Companies, Strongest to Weakest," Standard & Poor's Commentary Report, June 22, 2007, p. 1.

[64] Standard & Poor's Corporate Ratings Criteria 2006, p. 20 (available at http://www.corporatecriteria.standardandpoors.com)

understood in financial theory, and explained in Vilbert Direct,[65] it is only the risks that investors cannot eliminate by diversification that affect a company's expected return on equity. In the context of selecting a sample of companies of similar business risk, it is the similarity of *non-diversifiable* business risk that should be considered, and not the similarity of total risk.

Q54. Have you tested whether a company's systematic risk is related to its S&P business risk profile?

A54. Yes. Consider the results of the following table, which shows the average beta of utilities within each S&P business risk profile, for the sample of utilities listed on Schedule 7 of Exhibit ____(LJH – 1) in Hubert Direct:[66]

S&P business risk profile	1	2	3	4	5	6	7	8
Bloomberg adjusted beta	0.73	0.71	0.84	0.75	0.87	0.88	0.77	0.82

The beta estimates do not increase consistently with an increase in the S&P business risk profile as it should if the business profile rating were a measure of equity risk. Indeed, a formal test of the relationship between the two measures, performed by means of a linear regression of beta on the S&P risk rating, does not yield a statistically significant relationship for the sample of utilities listed by Hubert Direct in Schedule 7.[67]

Q55. What do you conclude from these results?

A55. These results show that the Hubert Direct's conclusion that the Vilbert Direct's samples are not of similar business risk to WEPCO and WG for the purpose of estimating the return on equity is without foundation.[68] The Hubert Direct misinterprets the S&P business risk profile ratings as a measure of a company's systematic or business risk, which is not consistent with the rating agency's description of how the business risk ratings are calculated and has no empirical support in the sample of utilities used by Hubert Direct.

---

[65] Vilbert Direct, Appendix C, pp. C-9 – C-10.

[66] This analysis is based upon 60 of the 70 companies in Schedule 7. I found no S&P business risk profile for eight companies and no Bloomberg beta estimate for 2 companies.

[67] A similar test of unlevered betas also did not show a relationship between the S&P business risk profile and beta.

2. Financial Ratios and Capital Structure

Q56. The Hubert Direct calculates the financial ratios used as one input to a company's credit rating and concludes that the percentage of equity in the regulatory capital structure is higher than necessary to qualify for an A-rating.[69] Do you agree that this is evidence that the equity percentage is too high?

A56. No. The conclusion that the equity ratio in WG's regulatory capital structure is higher than required to maintain an A credit rating does not follow from the Hubert Direct's analysis. Financial ratios are important, but they are only one of many inputs considered by the rating agencies in the determination of the credit rating to award. Focusing strictly on the financial ratios without consideration of the other factors leading to the rating achieved is unwarranted, as is documented by reference to statements by the rating agencies themselves.[70] Moreover, before considering any reduction in the regulatory equity ratio based upon the prospective financial ratios, it would be important to understand why WG does not have a higher credit rating today given that the same financial ratio analysis could have been done in the years past.

Q57. Do you have any evidence on the factors that may have prevented a higher credit rating for WG?

A57. It is always wise to be cautious when specifying how the rating agencies arrive at a particular rating, but in October 2006, Moody's published a report on the ratings factors of the companies in the gas LDC industry.[71] WG is covered in the report which is included as Exhibit No. MJV-R1 to this rebuttal. As shown in the report, historical financial ratios would indicate a higher rating than has been awarded to WG, but a number of other factors indicate a lower rating than has been awarded. Presumably, it is these other factors that prevented a higher credit rating.

---

[68] Hubert Direct, p. 38.

[69] Hubert Direct pp. 15-17, 31.

[70] S&P's Ratings Direct, June 02, 2004, Research: New Business Profile Scores Assigned for U.S. Utility and Power Companies; Financial Guidelines Revised, page 3: "…ratings analysis is not driven solely by these financial ratios, nor has it ever been. In fact, the new financial guidelines that Standard & Poor's is incorporating for the specified rating categories reinforce the analytical framework whereby other factors can outweigh the achievement of otherwise acceptable financial ratios."

[71] Ratings Methodology, "North American Regulated Gas Distribution Industry (Local Distribution Companies)", October 2006.

Q58. What is the danger of reducing WG's regulatory equity ratio from the filed 52.2 percent to the Hubert Direct's recommended 44.1 percent?

A58. The Hubert Direct suggests that reducing the equity thickness would "allow WG to remain within S&P's guidelines based on an A-rating"[72], but decreasing the regulatory equity ratio risks a larger credit downgrade for WG than anticipated because of the difficulty of knowing precisely how the current rating has been determined. A lower credit rating translates into higher costs for debt and reduces the WG's financial flexibility. Reduced financial flexibility translates into less ability to issue low cost debt during all portions of the business cycle. Finally, decreasing the equity ratio, increases financial risk for WG and would require an increase in the allowed return on equity to compensate.

IV. CONCLUSIONS

Q59. Please summarize your conclusions.

A59. This rebuttal makes three main points.

1. Although the implementation of the standard models differs, the failure to consider financial risk is the primary source of the differences in the recommended costs of equity between the Vilbert Direct and the Hubert Direct and the Baudino Direct. The ATWACC approach used in the Vilbert Direct is not an attempt to target or maintain any market-to-book ratio. Instead it simply adjusts the return on equity so that the market determined overall cost of capital rate of return on companies of similar business risk is applied to the book value rate base. Moreover, it is difficult for anyone to argue that the actual dollars of equity return would be sufficient to maintain the market-to-book ratio. Putting aside the larger problem of ignoring financial risk, there are material problems with their different implementations as well. The Hubert Direct and Baudino Direct make several assumptions in their implementation of the cost of capital implementation methods that lead to an underestimation of the cost of equity for the Applicants.

[72] Hubert Direct, p. 15.

2. Consideration of the off-balance sheet debt of the companies in the electric sample relative to WEPCO does not change the recommended cost of equity for the Company. The sample companies have about the same percentage of imputed debt as does WEPCO.

3. The S&P Business Risk Profile is a measure of the total risk of a company, not its systematic or market risk that would measure its cost of capital. Therefore, screening companies in the same industry out of a sample because of different S&P Business Risk Profiles would be an inappropriate use of the Business Risk Profile. Similarly, relying solely on estimated financial ratios to determine the regulatory capital structure gives more weight to the ratios than the ratings agencies would do.

Q60. Does this complete your rebuttal testimony?

A60. Yes.

North American Regulated Gas Distribution Industry (Local Distribution Companies)

Summary

The purpose of this methodology is to provide investors and other interested parties with a clear understanding of how Moody's assigns ratings to issuers and their obligations in the North American local gas distribution (LDC) sector. Our goal is to help the market understand the factors we consider most important for this sector and how they map to specific rating outcomes. Readers should be able to use this report to gauge a company's ratings within two notches.

This rating methodology covers 30 gas utilities in North America (Canada and the United States) all of whom are regulated by their provincial, state or municipal utility commissions. These are relatively small companies that are limited to a particular franchise territory and which ordinarily would not carry investment grade ratings were they not protected through regulation and assured the certainty of a positive gross margin in exchange for the public expectation of a reliable and safe gas distribution service.

Overall, Moody's analysis of gas utility companies focuses on the following core rating factors:

1. Sustainable Profitability
2. Regulatory Support
3. Ring Fencing
4. Financial Strength and Flexibility

In addition Moody's analyzes factors that are common across all industries such as liquidity, corporate governance, event risk, and legal structure.

About the Rated Universe

The focus of this rating methodology is on the "pure" gas LDCs in North America. We note that this methodology is concerned principally with operating utilities regulated by their local jurisdictions and not with gas utilities owned by parent holding companies that have other non-regulated businesses.

It is anticipated that a separate rating methodology will be forthcoming that would govern the ratings of such "diversified" gas companies including those that may have expanded through non-utility subsidiaries into other non-LDC businesses such as sales of unregulated electric power and gas contracts (energy marketing), gas pipeline transmission and storage, gas gathering and processing, exploration and production, energy trading or businesses that are non-energy related activities (e.g. real estate development or underground construction services).

Additionally, a third rating methodology would also be forthcoming for the gas pipeline companies, completing the three sub-sectors that make up the largely regulated natural gas transmission and distribution industry in North America.

In all Moody's rates 30 companies in the pure gas LDC sector in North America with EBITDA ranging from US$ 32 million to US$ 681 million and total assets ranging from US$ 382 million to US$ 5,974 million. The rated universe stretches from the east coast to the west and ranges in complexity from utilities with jurisdiction in a single state to those with multiple state jurisdictions (such as Atmos Energy Corporation, which has utility operations in 12 states).

Industry Overview

The guiding principle behind gas LDCs is that they are regulated entities within their jurisdictions and are expected to conform to the regulatory framework established by their regulators. The regulatory framework may specify a pre-approved level of capitalization, return on equity, the pass-through of certain cost components and the recognition of a specified level of regulated assets within the base rates established for customers, and the setting of a depreciation schedule based on the average life of plant and equipment. In Canada, regulators may operate at the provincial level. In the United States they might operate at the state or municipal level. As these companies are regulated by local authorities, there are tremendous variances in regulatory frameworks, some more favorable to the utility companies than others.

Allowed rates of return on equity are generally modest (ranging from 9%-12% in most cases depending on cost of capital). This creates certain tradeoffs that are meant to ensure a safe and reliable public service in return for stable and predictable levels of income and cash flow.

HIGHLY SEASONAL DEMAND AND WORKING CAPITAL REQUIREMENTS

The gas distribution business in North America is generally highly seasonal and sensitive to weather variations from one year to another. The vast majority of earnings are derived during the winter heating season (typically, the five months from November through March). In the summer months LDCs usually break even or lose money.

In addition, LDCs are typically subject to vast swings in working capital requirements, with the build-up of natural gas inventory in underground storages occurring during late spring and early summer, reaching a peak in November/December and falling during the course of the winter as gas is consumed. Accounts receivables begin to build in November and generally peak in late December or January. The buildup of short-term debt to meet seasonal working capital needs follows the same winter inventory build-up and accounts receivables financing pattern, with many LDCs completely out of short-term debt by April/May.

In an attempt to standardize the measure of heating days in the year, the industry has adopted the use of "heating degree days," commonly defined as the extent to which the daily average temperature falls below 65 degrees Fahrenheit, (generally assumed to be the point at which individuals would typically heat their homes). The number of heating degree days in a given year are compared against a historical "norm" specified by a regulatory commission in a specific jurisdiction to establish the degree of normalcy within a time frame. This time frame can range anywhere from 10 to 30 years, depending on the formulation approved by the utility regulators.

In some jurisdictions, the earnings impact of weather variations is neutralized through the establishment of weather mitigants as part of fundamental rate design. In its rate applications to the local regulatory commission, the local utility would request protection from weather that is warmer than normal for itself and for its customers when weather is colder than normal. Specifically, weather is compared with current deviations from historical norms as measured in heating degree days. The term often associated with this formal mechanism to compensate a utility for warmer than normal weather (or to compensate a consumer for colder than normal weather) is commonly referred to as a "weather normalization clause" or "WNC."

In jurisdictions that leave LDCs to their own devices, LDCs can either go "naked," or they can purchase weather derivatives or weather insurance to mitigate the effects of margin variations caused by fluctuating weather conditions.

PASS-THROUGH OF NATURAL GAS PRICES

In addition to the fact that gas LDCs are subject to regulation by local authorities, they also operate under the premise that their fixed and variable operatiing costs are borne by their firm demand customers (usually residential and commercial) who use gas for space heating, cooking, or a combination of both. Under the terms of the LDC operating structure, the LDC is not expected to assume the commodity risk of gas, but is able to pass this cost through to customers in monthly bills. Depending on the gas prices at any given time, the commodity price component of a residential customer's monthly bill could be as high as 80%. The remaining 20% would be the LDC's charge for operating and investing in the infrastructure of its gas distribution system (which are, primarily, its fixed costs of operation).

With the advent of third-party gas commodity marketers, this commodity charge is often provided by gas suppliers to consumers utilizing the LDC's gas delivery network. Under this mechanism of "distribution only" charges, the LDC can sometimes use the gas marketer to bill for its 20% of distribution charges, thereby transferring bad debt and risk of non-collection to the gas marketer. More often however, the LDC bills customers for both the gas marketer's commodity supply charges as well as its own delivery charge, retaining bad debt on its own books.

In several jurisdictions, utility regulators have granted LDCs a "bad debt" tracker, which allows them to recover the costs of non-collection via their customers' rate bases or as part of the PGA (purchase gas adjustment clause). Some states such as Pennsylvania and Tennessee have increased the amount of real-time bad debt that could be passed-through to the customer and are also allowing delivery termination for non-paying or delinquent customers to protect the margins of the LDC.

STABLE AND PREDICTABLE EARNINGS AND CASH FLOW

If weather variations are largely mitigated, cost of gas is a pass-though commodity cost, and regulators permit the company to recover its cost of investment and other operating costs for maintaining the gas distribution system, the earnings of the LDC should, theoretically, be largely predictable and cash flows should be stable year after year.

In reality however, LDCs' earnings are not stable, as customers continually find ways to conserve on heating bills, to purchase more efficient appliances or to build better insulated homes. All of these measures result in gas "conservation" and diminishing earnings (again, revenues are largely dependent on the volume of gas consumed). In areas of high growth — i.e. where the customer base is increasing at rates in excess of 3% p.a. — there is also the added pressure of rising operating and maintenance expenditures as well as the need to catch up with lagging capital investment recoveries. These pressures, coupled with rising cost structures and a volatile energy environment oftentimes require an LDC to file more frequent rate cases requesting cost recoveries or changes in fundamental rate design to account for secular changes in consumer behavior patterns that affect the operating margins of the gas utility.

Key Ratings Issues Going Into the Next Decade

The key rating issues affecting the near and medium term fall into three general areas:

- Rising gas prices
- The push for conservation
- The rise of mergers and acquisitions

RISING GAS PRICES

Gas prices follow many of the pressures that bear on oil prices, but also demonstrate characteristics of their own. Historically, North America was an abundant producer of natural gas. What the US could not supply from its own gas fields could be obtained reliably from Canada. Over the years, Canada has been consuming more of its gas, both to supply its own citizens' needs and to recover heavy oil lodged in sand formations where gas is burned underground to facilitate the oil recovery mechanism.

Also affecting the industry is a change in the pattern of the summer lull in gas prices. This is attributable to the fact that the electric power industry has been building new generation plants fueled by gas, mainly because of gas' clean-combustion characteristics. The vast majority of new electric generating plants built in the past few years have been fired by gas and these power plants burn more summer gas to generate electricity to meet cooling demands. As a consequence, the traditional lull in summer gas prices has become less reliable with the increased volatility in gas commodity pricing.

Rising demand for natural gas has also diminished the supply cushion to the point that hurricane disruptions such as those in the gas producing areas of the Gulf of Mexico in 2005 created logistical delivery disruptions to certain LDCs in the southeastern portion of the US. This confluence of increased gas demand and supply constraints is likely to maintain upward price pressure on natural gas prices over the medium term.

High gas prices have the undesirable effect of causing a rise in bad debt expenses and uncollectible receivables for many gas utilities, creating yet more need for rate design improvements.

THE PUSH FOR CONSERVATION

Another consequence of high gas prices is consumer motivation to burn less gas when possible. We have observed an impetus to reduce consumption in response to rising prices over the past decade. In North America this trend is most noticeable within the most rapidly growing home building areas, where homes are being built with better insulation. Another impetus for conservation is rising gas prices and warmer weather, where it is relatively easy for homeowners to turn-down the thermostat for extended periods of time, reducing gas margins earned by LDCs that are dependent on volumetric gas consumption for cost recoveries.

Conservation is an important component in balancing the region's gas supply and demand equation, but under traditional regulatory frameworks in many jurisdictions, few gas utilities have the incentive to encourage gas conservation or promote education in gas usage efficiencies among their customers. With the likelihood that gas prices will remain high and volatile, conservation will likely become a more formidable influence on gas consumption in the residential and commercial customer segments going forward.

In the US, utility commissioners in various states differ in their approaches to allowing their gas utilities to recover lost margins attributable to conservation-driven variations in consumption. Commissions with more supportive regulatory frameworks tend to allow mechanisms for revenue recoveries and their utilities generally have stronger financial profiles.

As more LDCs become aware of the impact that conservation initiatives have on their customers' gas usage and their own profitability, more are considering applying for the appropriate rate design changes. To do this, however, they must first build understanding and support at the grassroots level. Overall, utility rate designs that compensate gas LDCs for conservation-based margin losses (as with variations due to weather), should help to stabilize utilities' credit metrics and credit ratings. Utilities with these ratemaking mechanisms also tend to carry higher credit ratings.

THE RISE OF MERGERS AND ACQUISITIONS

With the repeal of the Public Utility Holding Company Act (PUHCA) in the US (February 2006) companies are finding fewer obstacles to mergers across state lines. Companies seeking to expand their service territories are now finding it easier to bid for companies seeking an opportunity to cash out (as price multiples are currently attractive for sellers in this industry).

The pace of industry consolidation as well as the introduction of new players could accelerate beyond 2006. From a credit standpoint, however, we note that mergers and acquisitions usually entail taking on more debt, attempts to create new operating synergies, and the need to apply for further rate relief from regulators. Previous periods of heightened mergers and acquisition activity were typically associated with increased numbers of ratings downgrades, as LDC debt levels and operating costs rose and rate recoveries lagged. While it is still early to predict whether past performance will repeat itself in the current merger-driven environment, the denigration of credit metrics remains a possibility.

In This Methodology

To explain Moody's approach to rating gas utility companies, we take the reader through the following steps:

IDENTIFICATION OF KEY RATING FACTORS

To determine the rating of a gas utility company we focus on the following factors:

1. Sustainable Profitability
   - Return on Equity
   - EBIT to Customer Base
2. Regulatory Support
   - Regulatory Support and Relationship
3. Ring Fencing
   - Ring Fencing
4. Financial Strength and Flexibility
   - EBIT/Interest
   - Retained Cash Flow/Debt
   - Debt to Book Capitalization (excluding goodwill)
   - Free Cash Flow/Funds from Operations

MEASUREMENT OF THE KEY RATING FACTORS

For each of the core factors cited, we present a set of metrics or "sub-factors" that enable the reader to determine exactly how we measure this factor. Each of the core factors is comprised of between one and four sub-factors, each of which are mapped to a rating or score. For example, we consider four different financial metrics within the Financial Strength and Flexibility Factor.

In total this rating methodology incorporates eight sub-factors. Where possible, we provide quantitative metrics derived from a company's financial statements. For some factors, however, non-statistical observation is necessary to determine the appropriate results. For each of the eight metrics, we assign a weight based on relative importance.[1]

Moody's applies a total weighting of 20% for non-financial observations and 80% for financial. (However, we weigh some sub-factors more heavily than others, as some sub-factors such as the ROE (return on equity) and the ones for Financial Strength and Flexibility weigh more heavily in determining the relative risk of a particular LDC in comparison with its peers). This is because, while regulatory design and support may differ from jurisdiction to jurisdiction, the financial metrics do not. This renders them more easily comparable across political boundaries and more quantifiable. Financial observations also tend to be lagging indicators, as they come at the end of a fiscal reporting period and serve as the final scorecard for the issuer. The two non-financial sub-factors tend to be less definitive and are more subject to interpretation. Applying the sub-factor weightings and scoring the rating assignment for each sub-factor in this manner results in ratings that track our assigned ratings within one or two notches in 93% of the cases.

While Moody's outlooks are forward looking, the rating process does make extensive use of historic financial statements. Historic results help us understand the pattern of a company's results and how it compares to peers. They also provide perspective, helping to ensure that estimated future results are grounded in reality. This document makes use of historic data primarily. However, if an LDC is undergoing a rate case or fundamental business transformation — negating the usefulness of past performance as a guide to future credit standing — we use projected financial results instead.

Where historical financial results are used, metrics are based on an average of the most recent three years. The 2003 through 2005 periods provide a good cross-section of the peaks and troughs that characterize individual company performance over a normalized period.

Where projected financial results are used, metrics are based on an average of the 2006 through 2008 periods, or in some cases, 2007 through 2009, depending on the implementation dates of rate increases or realization of expected merger combinations.

All measures incorporate Moody's standard adjustments to income statement, cash flow statement, and balance sheet amounts including under-funded pension obligations, recurring operating leases, and off-balance sheet commitments and contingencies.[2] Moody's Credit Opinion key indicator ratios will also incorporate these standard adjustments.

MAPPING OUR METRICS TO RATING CATEGORIES

After identifying the measurements for each factor, the potential outcomes for each of the eight factors/sub-factors are mapped to a Moody's rating category (i.e. Aaa, Aa, A, Baa, Ba, B, Caa). For example, we specify what level of ROE is generally acceptable for an Aa credit versus an A credit. We provide a range or description for each of the measurement criteria.[3]

COMPANY MAPPING/ OUTLIER DISCUSSION

We next assign a rating to each company in our rated universe for each factor. We also show how this rating compares to the company's actual assigned rating. The results of this mapping appear in a summary table located in Appendix B, as well as in the results section under each factor.

We recognize that any given company may perform higher or lower on a specific factor than its actual rating level. These companies are identified as "outliers" for that factor. A company whose performance on a specific factor is more than two rating notches higher than its actual rating is deemed a positive outlier for that factor. A company whose performance is more than two notches below is deemed a negative outlier. We highlight those companies whose factor mapping is more than two notches higher or lower than its rating and offer a discussion of the general reasons for outliers within a given factor.

---

1. *See Appendices A and B for a summary of sub-factors and weightings for each sub-factor.*
2. Moody's Approach to Global Standard Adjustments in the Analysis of Financial Statements for Non-Financial Corporations — Part I *(US/Canadian GAAP, February, 2006).*
3. *See Appendix D for non-financial sub-factor definitions.*

DETERMINING THE FINAL RATING

To determine the overall rating, each of the eight assigned sub-factor ratings is converted into a numeric value based on the following scale.

1	3	6	9	12	15	18
Aaa	Aa	A	Baa	Ba	B	Caa

Each sub-factor's numeric value is multiplied by an assigned weight (refer to the table below and/or Appendices A and B, for weights), and then summed. For information purposes, the table below also shows sub-totals and how much weight is given to each broad rating factor.

Factor	Sub-Factor	Weighting	Cumulative Weighting of the Relevant Sub-Factors
Sustainable Profitability	ROE	15%	20%
	EBIT/Customer Base	5%	
Regulatory Support	Regulatory Support	10%	10%
Ring Fencing	Ring-Fencing	10%	10%
Financial Strength and Flexibility	EBIT/Interest	15%	60%
	RCF/Debt	15%	
	Debt/Book Capitalization	15%	
	Free Cash Flow/FFO	15%	
Total Weighting		100%	

The total is then mapped to the table below, and an overall alpha-numeric rating is assigned based on where the score falls in the range. The outcome provides a good correlation, with indicated ratings falling at or two notches away from actual ratings.

Indicated Rating	Overall Score
Aaa	= 1
Aa	> 1 < 4.5
A	>= 4.5 < 7.5
Baa	>= 7.5 < 10.5
Ba	>= 10.5 < 13.5
B	>= 13.5 < 16.5
Caa	>= 16.5

The entire array of scores and mappings for each of the LDC companies is shown in Appendix B.

Factor Discussions

FACTOR 1: SUSTAINABLE PROFITABILITY

Why It Matters

Two subfactors provide good indications of a firm's ability to remain profitable and efficient despite the inherent volatility associated with the sector:

- Return on equity (ROE), which is calculated for each year by taking a company's profitability in a given year and dividing it by an average equity of the current and previous year end. ROE serves as barometer of a company's general level of profitability — and when calculated over a period of years, serves as an indicator of its ability to sustain its profitability — and provides a good starting point for understanding the overall efficiency of the operations of the company.
- Operating Income (EBIT) relative to customer base provides another indicator of a gas utility's overall operating profitability relative to the number of customers being serviced. The higher this figure, the more each customer contributes to the company's "bottom-line." For purposes of this calculation, only firm demand customers of the residential and commercial categories are included, as industrial customers often have alternate

sources of fuel and are the first to be cut off by a utility in the event of gas pro-rationing (allocation as a percentage of available supply) or shortage.

The former calculates returns on a GAAP basis and the latter serves as a measure of overall operating efficiency. When an average of three years is used as the comparable period, these indicators reveal the company's relative profitability and ability to maintain this profitability and efficiency on a sustainable basis.

LDCs may differ in their rate design, the effectiveness, and the timeliness of rate design, but they ultimately culminate in an ROE scorecard that is an irrefutable indicator of the profitability that the firm has achieved (or in the case of projected figures resulting from a rate case filing or decision, projected profitability) given the business environment in which it operates. Similarly, the EBIT/customer base measures the relative operating efficiency of the company in achieving these operating results.

Among the risk factors reflected in ROE are the presence and effectiveness of the LDC's weather normalization clause (WNC), its ability to increase earnings despite customer gas conservation, the ability of the firm to pass through bad debt expenses, to true-up for underfunded pension liabilities, the frequency and degree of price adjustments for gas cost purchase adjustments, the ability to pass along financial and derivative hedging costs to consumers, to reimburse itself for environmental remediation expenditures, to use forward year test data in factoring in capital expenditure cost recoveries, and its ability to cover rising O&M (operating and maintenance) expenditures. The firm's effectiveness in dealing with these risks is distilled into an ROE calculation. Over time, this calculation provides a profile of the company's ability to generate consistent earnings that are capable of covering the cost of doing business and capable of doing so over an extended period of time. It also provides a benchmark measure of efficiency relative to other LDCs with similar business profiles.

It should be noted that in the use of ROE, the measure of profitability is indifferent as to whether an LDC employs multiple approaches to shielding itself from gas commodity price volatility (such as through use of various forms of financial derivatives) or if it relies primarily on underground gas inventory storage or long-term pipeline deliveries at fixed costs. Similarly, it does not impose a requirement that the LDC have a WNC in place to protect its gas margins against warmer than normal winters, as the company could achieve similar results by employing its own form of weather mitigants through the purchase of weather insurance or derivatives. The importance of achieving a desired target ROE is the fact that it signals management's effectiveness in employing all possible measures to achieve its business goals.

That said, the better the quality of an LDC's rate design or effectiveness in generating operating profits, the greater and more consistent its ROE. Very few businesses are assured a stable and consistent return on their capital by a regulatory body, but LDCs are (in theory, at least). To the extent they employ highly effective rate designs and business solutions in mitigating the known risk factors in the business, the better the ROE and efficiency of its operations.

Despite wide variations in individual utility rate designs therefore, ROE and EBIT/Customer Base appear to capture the level of profitability and efficiency in an LDC's operations and reflect its ability to generate profits over a sustainable period of time.

We note that profitability (ROE), operating income to customer base (EBIT/residential+commercial customers), interest coverage, retained cash flow to debt, debt to capital and free cash flow to funds from operation are the credit metrics that contribute the most to differentiating the stronger LDCs from the weaker ones. These also tend to be the "lagging" indicators as financial results are only available after the close of a fiscal quarter. Thus, they serve as a report card for the close of a given financial period, after all the events of the period have already transpired and all the initiatives of management are either completed or left undone.

Measurement metrics for this factor are as follows:

- ROE — profitability in a given year / average equity of the current and previous year.
  Weighting: 15%
- (EBIT) to Customer Base: For purposes of this calculation, only firm demand customers of the residential and commercial categories are included, as industrial customers often have alternate sources of fuel and are the first to be cut off by a utility in the event of gas pro-rationing (allocation as a percentage of available supply) or shortage.
  Weighting: 5%

Factor Mapping: Sustainable Profitability

	Weighting Ranges	Individual Weighting	Aaa	Aa	A	Baa	Ba	B	Caa
Return on Equity	20%	15%	> 19%	14 – 19%	9 – 14%	5 – 9%	2 – 5%	0 – 2%	< 0%
EBIT/# of Residential & Commercial Customers		5%	> $350	$250 - $350	$150 – $250	$100 – $150	$50 – $100	$0 – $50	< $0

Company Mapping Results: Sustainable Profitability

Issuer Name	Current Senior Unsecured Rating	ROE	Indicated Rating: ROE	EBIT/# of Residential & Commercial Customers	Indicated Rating: Operating Ratio
Alabama Gas Corporation	A1	14 – 19%	Aa	$150 – $250	A

Positive Outlier
Negative Outlier

Observations and Outliers

ROE

Among the negative outliers are Boston Gas and Colonial Gas, two of six natural gas distribution companies owned by KeySpan Corp. Their low ROE reflects push down accounting relating to KeySpan's acquisition of Eastern Enterprises, whereby a portion of the acquisition debt and goodwill issued by the parent have been allocated to Boston Gas and Colonial Gas. The debt and parent financing of working capital and gas inventory through the utility money pool has resulted in noticeably increased debt and interest expense levels. Additionally, National Grid's recently announced plan to acquire Keyspan raises the possibility of an additional debt servicing burden being "pushed down" to these subsidiaries. The low ROE also reflects the lower efficiency of the rate design in these KeySpan subsidiaries. The lack of

weather mitigation and conservation in the company's rate design leaves it vulnerable to weather and conservation exposure, which are being mitigated in part through the purchase of weather derivatives.

The Connecticut LDCs of Connecticut Natural Gas, Southern Connecticut Gas and Yankee Gas also have low ROEs relative to their assigned ratings, reflecting relatively poor regulatory support from the state commission on weather and conservation protections, and the ability to pass financial hedging costs to rate-payers as a means to mitigate gas price volatility. These LDCs are also smaller subsidiaries within larger electric power utility operations that may require additional forms of parental support for the LDCs.

In the case of Wisconsin Gas the company was approved for a rate base increase, effective January 2006, for an approved ROE of 11.2%, but historical returns had eroded because of a five-year rate freeze.

Among the positive outliers are UGI Utilities, AGL Resources and Atmos. Although UGI has a high ROE relative to its peer group, the overall rating is suppressed because of its affiliation with non-investment grade subsidiaries of the parent.

In the case of AGL and Atmos, the diversified earnings of the group include income from operations such as energy services. These tend to boost the group's returns even though the combined risk may indicate a less stable and predictable earnings stream.

EBIT to Customer Base

Northern Illinois Gas and North Shore Gas Company are negative outliers in this operating efficiency ratio, as they have been suffering from regulatory lag. However, the recent rate increase in the case of Northern Illinois Gas could help narrow the gap in its performance going forward.

On the other extreme, UGI appears to be a very efficient operator and is a positive outlier from a customer base standpoint. Although UGI has strong operating income (being supported by a higher than average customer growth rate — mostly attributable to organic growth), the overall rating is suppressed because of its affiliation with non-investment grade subsidiaries of the parent.

FACTOR 2: REGULATORY SUPPORT

Why It Matters

The fact that LDCs are subject to regulation by local authorities has a direct bearing on the success of their business operations. It is difficult for utilities to function without good community relations, as they depend on their local regulators and on the public's understanding to obtain the rate relief and cost recovery necessary for a gas distribution system's investments.

Of particular importance, regulatory requirements are often delineated not by law or by prescribed statutory requirement or ruling but rather by the expectation that traditional practices will continue and that LDCs — particularly the older and more established ones — will continue to act within established boundaries and in accordance with past practice. This necessitates a strong relationship with regulators who are, ideally, supportive.

Thus, when the regulatory relationship is strong and cooperative, utilities are able to engage in active dialogue with regulatory commissioners and staff to find mutually acceptable solutions to utility problems (such as rising account delinquencies in periods of gas shortages and price increases) or to educate customers about key initiatives such as gas conservation. In a strong relationship, the commission staff might also serve as a technical advisor to the utility commission in facilitating constructive discussions with the company — as opposed to playing the role of "consumer advocate" and countering LDC initiatives.

One very important component of the utility/regulator relationship is the ability of the utility to recoup allowed expenses in a timely manner and its ability to earn its fully-allowed rate of return (without having to file continuously for new rate cases).

Within this metric we also include the utility's relationship — both perceived and actual with the public and its approach to issues of safety, reliability and integrity.

This metric thus helps to define credit impact of the established operational "norms" and the operating framework. It is conceivable for a utility to maintain an investment grade rating with only limited support from its regulators if it has capable management that is able to find alternatives and solutions for its business needs, but the support of regulators on most matters of economic importance enable a company to operate with far more effectiveness. We note that, included in the definition of "regulatory environment" are regulatory staff, commission, interveners, consumer advocates and the public at large.

Measurement metrics for this factor are as follows:

- Quality of Regulatory Support: The regulatory relationship is measured on a scale from "Exceptional/ Proactive" to "Inadequate/Weak." To assess the quality of the regulatory support we examine the strength of the regulatory relationship. This will include the speed and degree of willingness with which the regulatory commission approves requests for rate increases, approves and encourages rate design modifications that serve to help a utility recoup its operating and capital investment costs and whether regulators enable utilities to recoup such costs in a timely manner.
  Weighting: 10%

Notes on Measurement Criteria

This sub-factor is important and will have a direct bearing on the ultimate credit rating of the LDC, although it lacks the finality of the more formulaic financial sub-factors (regulatory decisions may be modified or reversed by future regulators or a court action, whereas ROE results, for example, cannot). Because regulatory support is often subject to interpretation and change over time as the actions and views of participants change, it is weighed less heavily than are financial metrics.

Factor Mapping: Regulatory Support

Weighting Ranges	Individual Weighting	Aaa	Aa	A	Baa	Ba	B	Caa
10%	10%	Exceptional Proactive Support by Utility Commission to allow LDCs to timely adjust rates to cover all costs of service; Utility commission alwayswilling to help LDC establish a cooperative framework for discussions, hearings and implementation of better rate design to help LDCs' shareholders and consumers alike. Utility Commission grants all rate design features to allow LDC to recover costs on a complete and timely basis.	Very Good Proactive Support by Utility Commission to allow LDCs to timely adjust rates to cover all costs of service; Utility commission highly willing to help LDC establish a cooperative framework for discussions, hearings and implementation of better rate design to help LDCs' shareholders and consumers alike. Rate design is near "bulletproof" cover for LDC risks. Requested rate increases tend to be approved in less than 9 months.	Good Support by Utility Commission to allow LDCs to amend rate designs. Company gets good support in proposing new solutions to deal with common utility problems such as conservation and weather variables; Differences between LDCs and utility commission are likely to be resolved. Rate filings tend to be approved under 12 months.	Reasonable support from Utility Commission to allow LDCs to recoup allowed expenses; Company gets some support in proposing new solutions to deal with common utility problems such as conservation and weather issues; Differences between LDCs and Utility Commission are reasonably resolved in a timely manner and rate cases tend to be approved in 12 – 15 months with at least 50% of LDC's target requests being granted.	Inadequate support from Utility Commission to allow LDCs to recoup allowed expenses; Utility commissioner and/or staff tends to play the role of "consumer advocate" that often counters proposals or initiatives advanced by the LDC. Cases often take over 15 months to resolve or LDC is frozen out of rate filings for over 18 months.	Inadequate support from Utility Commission to allow LDCs to recoup allowed expenses; Utility commissioner often plays the role of "consumer advocate" that tends to counter proposals or initiatives advanced by the LDC; Company is seldom involved with working on special task forces to deal with issues of rising account delinquencies or educating customers on conservation or warm weather issues. Utility suffers from increasing regulatory lag and lacks rate relief necessary to earn allowed ROE.	Inadequate and weak support from Utility Commission to allow LDCs to recoup allowed expenses. Utility commissioner always plays the role of "consumer advocate" that tends to counter proposals or initiatives advanced by the LDC; Company is hardly ever involved with working on special task forces to deal with issues of rising concern to utility or customers. Unsupportive commission/ state legislature or consumer base. Utility can't earn allowed ROE.

Positive Outlier
Negative Outlier

FACTOR 3: RING FENCING

Why it Matters

- **Ring Fencing**: Many LDCs are owned by diversified energy companies engaged in non-regulated activities. For this reason, the degree to which an LDC is "ring-fenced" will have an impact on the quality and degree of protection afforded to the utility's assets and operating cash flows. Whether imposed by regulators, lenders, or by the parent company (self imposed) the ring-fencing must assure that the utility is self-standing and protected from non-regulatory businesses of the diversified parent group[4]. This is a common objective among regulators, lenders and consumers alike. Also, as in the case with weather mitigants, Moody's does not insist that there be explicit written statutes requiring the gas utility to be properly ring-fenced for the utility to be highly rated, as long as this is accomplished in an effective manner through other means.

  Among the contributors to a well ring-fenced utility are limitations on inter-company loans and advances to non-regulated affiliates or prohibitions on the commingling of funds through participation in diversified corporate money pools. These are important in ascertaining that the utility's operating assets and capital expenditures are justifiable to utility ratepayers.

  Other contributors to strong ring fencing are legal or regulatory requirements stipulating maximum leverage ratios for the LDC and requirements that an LDC remain investment-grade to preserve its service

4. *The expectation that non-regulated expenses incurred by affiliates engaged in other businesses will not be passed onto the utility (which would then attempt to seek recovery from its consumers) is intrinsic to the concept of ring fencing. For example, a diversified gas company with a gas trading operation is expected to deal with its regulated utility at arm's length. It is not expected that the company will allow the trading company to determine which entity should receive the best price quotes for gas purchase transactions or which should be chosen to book trading losses.*

franchise. By placing a limitation on leverage, regulators or lenders are implicitly limiting the level of dividends that a diversified parent company might extract from its utility, and discouraging the utility from using its balance sheet to raise debt for the benefit of non-utility affiliates or its diversified parent.

The utility's payment of dividends in excess of what the parent company may require for its public shareholders could also serve as an indication of poor ring fencing, as the surplus funds being paid as dividends by the utility could be viewed as a form of cash support for the parent company's non-utility affiliates. Well ring-fenced utilities typically raise their own funds and handle their own bank accounts, with non-utility affiliates establishing their own credit facilities and funding requirements separate and independent from the utility.

Weighting: 10%

- Less obvious, but also important are the proven resolve of management or a utility's board in erecting operating barriers that isolate the utility from its non-regulated affiliates. This might include, for example, dedicating separate utility gas purchasing agents from the group's energy trading arm or locating utility personnel at separate premises from those of the non-utility affiliates. These good corporate governance attributes are implied in having good ring-fencing measures.

  Utilities sometimes establish their own boards of directors, especially within a larger and more diversified company to ensure that their assets, cash flows and operating funds are properly separated and that attempts by the parent to distribute dividends to the holding company are fair and justified. Any weak corporate governance would typically become evident in reviewing a utility's ring fencing quality and manifest itself through lax policies and procedures in operations as well as in financial dealings, record-keeping and internal controls. Corporate governance therefore, is a related indicator for ring fencing quality.

  While such efforts as creating a permanent body to ensure the operating integrity of the utility could add to the strength of the ring fencing provisions, it is a further indicator that the utility stands on its own and is governed by a board that looks after its interest first rather than using the utility to advance the goals of the parent's diversified group. Ultimately, such efforts can enhance the utility's independent operating performance and credit rating.

  The utility's board may also require that it obtain its own credit facilities, issue its own bonds and only guaranty activities directly related to providing core utility services. Under this framework, the utility serves as its own profit center and allocates any expenses incurred on behalf of non-utility sister companies back to those affiliates for recovery, rather than burdening its own operating staff and the utility ratepayers.

Measurement metrics for this factor are as follows:

- Ring Fencing: This metric is assessed on a scale of "excellent ring fencing isolating utility from non-utility" to "inadequate and weak ring fencing: funds always commingled." In determining the degree of commingling of funds, LDCs range from having their own bank accounts and issuing their own debt and commercial paper to participating in combined cash money pools or engaging in making intercompany loans to non-utility affiliates on a frequent basis). Other indicators that we review for quality of ring fencing include: the level of dividends that are upstreamed by the utility to the parent vs. the parent to the public shareholders, the level of intercompany transactions, the ability of various operating entities to raise their own bank and public financing, the extent of any cross-default provisions or cross-guarantees, the presence of utility financial covenants that would enhance their ring fencing and signs of weak corporate governance.
  Weighting: 10%

Factor Mapping: Ring Fencing

Weighting Ranges	Individual Weighting	Aaa	Aa	A	Baa	Ba	B	Caa
10%	10%	Excellent ring-fencing provisions isolating Utility from Non-Utility; No commingling of funds; Utility cash accounts are separated from rest of company; Inter-company loans never permitted between utility and non-utility; No portion of Utility dividend payment to parent ever ends up being allocated to non-utility. Strong	Very Good ring-fencing provisions; Utility and Non-Utility highly unlikely to commingle funds; Separate cash program or own utility money pool; Inter-company loans not permitted between utility and non-utility; Utility dividend payment to parent never end up being allocated to non-utility.	Good ring-fencing provisions; Utility and Non-Utility are unlikely to commingle funds; Separate utility money pool or utility accounts; Inter-company loans not permitted between utility and non-utility; Utility dividend payment to parent unlikely to be allocated to non-utility.	Reasonable ring-fencing provisions; Utility and Non-Utility may need to commingle funds via consolidated corporate money pool; Bond indentures or bank credit agreements may reasonably restrict the utility from financial dealings with non utility; Inter-Company loans between utility and non-utility rare.	Inadequate ring-fencing provisions; Utility often participates in corporate cash money pool that includes non-utility and funds are often commingled; Regulators usually do not have a requirement that LDCs remain investment grade. Bond indentures or bank credit agreements may not restrict the utility financial dealings with non- utility.	Inadequate ring-fencing provisions; Utility often participates in corporate cash money pool that includes non-utility and funds are generally commingled; No requirement for LDCs to remain investment grade. Bond indentures or bank credit agreements usually do not restrict the utility financial dealings with non- utility. Inter-company loans between utility and non-utility common place.	Inadequate and weak ring-fencing provisions; Utility and Non-Utility generally always commingle funds; No requirement for LDCs to remain investment grade; Bonds indentures/ bank agreements never restrict utility financial dealing with non-utility. Inter-company loans between utility and non-utility are common place; Utility dividends to parent may fund non-utility needs.
		Corporate Governance protecting utility interests which are treated as core operation.	Very Good Corporate Governance. May lack formal regulatory or creditor leverage restrictions or IG requirement for utility, but company has strong policy of ring-fencing utility.	Good Corporate Governance of utility	Satisfactory Corporate Governance. Gas utility contributes less than 90% of consolidated group EBIT and may not be primary growth engine.	Inadequate Corporate Governance protection for utility as stand-alone entity.	Inadequate Corporate Governance for utility as a stand alone entity.	Inadequate and weak Corporate Governance of utility interests.

Positive Outlier
Negative Outlier

Observations and Outliers

Ring Fencing

Most of the indicated ring-fencing ratings are compatible with issuer assigned credit ratings. The "Aaa" ring-fencing indicators are typically reserved for those companies whose jurisdictions have established explicit requirements for separation of utility and non-utility businesses, maximum leverage, specific requirements that the LDC remain investment-grade or have placed limitations on dividends to their parent failing certain capitalization requirements. Exceptions might include Washington Gas Light Company, where despite the absence of specific regulatory requirements, the company has a strict policy of not commingling the gas utility funds with those of the non-regulated operations of the parent and the LDC only remits dividends to the parent that are required for distribution to public shareholders, prohibiting its LDC from assisting or supporting the business needs of its non-regulated affiliates.

In the case of Piedmont Natural Gas, Cascade Natural Gas and Southwest Gas Corporation, the utility is the parent company and there is no need for ring-fencing against a diversified non-regulated affiliate.

Negative outlier Alabama Gas results from the LDC having no explicit ring-fencing provisions from regulatory or financing agreements other than broad restrictions under an Alabama state statute.

Regulatory Support

Several "A" rated companies have outstanding regulatory relations and support "Aaa." Some examples include New Jersey Natural Gas Company, Northwest Natural Gas Company and Piedmont Natural Gas Company, where each one of these names have pioneered in the introduction of innovative service concepts and novel rate design concepts such as those for "conservation decoupling" in their respective jurisdictions and all have previously obtained WNC from their

regulators. The regulatory relationship for some of the "Baa" names have also improved to the point where they also scored high in this factor ("Aa"), such as Indiana Gas Company and Laclede Gas Company in Missouri, where these LDCs were the first companies to obtain weather protection mechanisms from their public utility commissions either in the form of formal WNC or through fixed demand charge rate design. Utilities that score high in this factor also tend to be leaders in scoring high on customer satisfaction responses to independent surveys, helping their utility commissioners forge solutions to common utility problems such as dealing with the cost of high gas prices, or providing safety and systems integrity solutions before major problems arise, while maintaining strong community relations.

FACTOR 4: FINANCIAL STRENGTH AND FLEXIBILITY

Why It Matters

Financial strength is an important indicator of an LDC's ability to meet its financial obligations, particularly in light of the volatile nature of the industry's performance[5]. The metrics we use to define this factor include the following:

- **Interest coverage** (EBIT/Interest) is a measure of financial flexibility in an LDC's credit agreement as some lenders require minimum coverage to maintain their credit lines (the concept being that a stable utility should, at a minimum, be able to pay its interest expenses if not amortize its debt over a reasonable time period).

  Interest coverage serves as an indicator of fixed charge coverage. We chose this coverage ratio as it is used in the financial covenants of many LDC bank credit agreements and bond indentures, and is, by extension, both conventional and accessible for comparative purposes. Naturally, the higher this fixed charge coverage, the greater the financial flexibility of the utility.
- **Retained Cash Flow to Debt** (RCF/Debt) is a measure of financial leverage as well as an indicator of the strength of a utility's funds from operations after dividend payments are made to service the debt. It serves as a measure of financial health as well as liquidity to cover debt obligations while also providing a measure of cash available for capital expenditures and to cover working capital needs. RCF/Debt also serves as a measure of leverage relative to operating cash available for debt service.

  The higher the level of retained cash flow relative to debt, the more cash the LDC has after paying dividends to support its capital expenditure programs. The stronger LDCs tend to have sufficient retained cash flow to cover capital expenditure needs, while the weaker ones tend to run cash "deficits" that must be covered through increased equity issuance or debt, or a combination of both. Usually, debt is issued first, followed by occasional equity issuance to meet specific project needs or to strengthen the balance sheet.
- **Debt to Book Capitalization (Excluding Goodwill)** is a more generic measure of financial leverage and has, in the past, been a good barometer with which to gauge the financial flexibility available for a utility to expand and grow in its operations when it has a debt load to service. This measure subtracts goodwill from capitalization because regulators typically do not give credit for premium paid on acquired assets.

  High leverage reduces a firm's operating flexibility not only because it raises interest expense but also because it limits the company's ability to raise additional capital to cushion the impact of poor business conditions. High leverage may also portend the approach of maximum allowed debt capacity under most bank credit agreements, which often set a 65% debt/capitalization borrowing limit for investment grade LDCs.
- **Free Cash Flow as a portion of Funds from Operations** (FCF/FFO) measures the amount of free cash flow as a percentage of funds from operations after dividends are paid, working capital changes are taken into account and capital expenditures are made. While this is a stringent indicator of a utility's cash flexibility, it is a good indicator of cash generating capability and flexibility to deal with unforeseen circumstances or emergencies (gas supply disruptions, production shortages, etc.) — and the accompanying side effect of rapidly rising gas commodity prices — while managing long-term dividend payouts, capital expenditure undertakings and possible upswings in working capital requirements.

  This ratio is generally negative for most LDCs, but it is nonetheless a measure of free cash generated from operating funds (net income + depreciation + deferred taxes +/- other non-cash charges). A ratio that is consistently positive would suggest that the LDC generates surplus cash from its operations. This is rare for LDCs to accomplish on a consistent basis (which is why there are few companies rated Aa or Aaa).

5. *To assess financial strength and flexibility Moody's "smoothes" credit metrics by averaging them over a three-year time horizon whenever possible. The three years chosen are usually in the past, unless the projected years incorporate highly probable events driven by rate changes.*

Measurement metrics for this factor are as follows:

- Interest Coverage: EBIT/interest
  Weighting: 15%
- Retained Cash Flow to Debt
  Weighting: 15%
- Debt to Capitalization (Excluding Goodwill)
  Weighting: 15%
- Free Cash Flow to Funds from Operations
  Weighting: 15%

Positive Outlier
Negative Outlier

Observations and Outliers

Interest Coverage

This ratio is generally compatible with LDCs' assigned credit ratings. Among the positive outliers in the "A" rated names is New Jersey Natural Gas, whose credit measures have proven much stronger than those for most of its peers. During the past few years earnings and cash flow improvements have resulted in higher interest charge coverage and lower leverage for the company. On the other end of the spectrum, Boston Gas Company shows higher interest expense to service relative to other similarly-rated high names.

In the "Baa" rated category we find that South Jersey Gas Company is rated lower than its interest coverage might suggest. This reflects the transitional nature of the company as it contemplates the issuance of additional debt in the future to help fund its capital expenditure requirements.

RCF/Debt

A positive outlier in the "A" rated category is Boston Gas, which has been able to produce strong cash flow under a performance-based rate (PBR) formula approved by regulators in Massachusetts. Negative outliers in the "Baa" category include Laclede Gas Company, where retained cash flow has been negatively affected by a policy of increasing dividend payouts.

Debt to Book Capitalization (Exduding Goodwill)

Low leverage generally correlates with high credit ratings, but there are a few exceptions. The "Ba" leverage factor score for Boston Gas Company and Colonial Gas Company, both subsidiaries of KeySpan, could be explained by the parent's use of push-down accounting. Under this approach, the LDCs were assigned a proportionate share of the cost of their acquisition debt and goodwill when KeySpan purchased them in 2000. The effect of pushing down a portion of the parent company's acquisition debt and goodwill raised financial leverage for these LDCs. This occurred not only because of the added debt burden from the parent but also because the allocated portions of goodwill resulted in a lower capital base (Moody's practice is to subtract the goodwill from equity for the regulated gas sector).

FCF/FFO

The scores for the free cash flow ratio are generally compatible with those of the assigned company ratings. A notable outlier in the "A" category includes Brooklyn Union Gas, which scored a "Ba" in this factor. During the past three years this company has had its cash flows stressed by a combination of high capital expenditures, high working capital uses and high dividend remittances to its parent. Outliers in the "Baa" rated names include South Jersey Gas, which is in transition, and Yankee Gas, which is in need of further rate relief and rate design improvements despite its recent rate filings, especially as it makes capital outlays in advance of rate recovery as in its current capital expenditures for construction of an LNG facility.

Final Considerations

To determine the overall rating, each of the eight assigned sub-factor ratings is converted into a numeric value based on the following scale:

1	3	6	9	12	15	18
Aaa	Aa	A	Baa	Ba	B	Caa

Each sub-factor's numeric point value is then multiplied by an assigned weight (as shown in Appendix A), summed.

Factor	Sub-Factor	Weighting
Sustainable Profitability	ROE	15%
	EBIT/Customer Base	5%
Regulatory Support	Regulatory Support & Relationship	10%
Ring Fencing	Ring-Fencing	10%
Financial Strength and Flexibility	EBIT/Interest	15%
	RCF/Debt	15%
	Debt/Capitalization (Ex. Goodwill)	15%
	FCF/FFO	15%
Total		100%

The total is then mapped to the table below, and an overall alpha-numeric rating is assigned based on where the score falls in the range.

Indicated Rating	Overall Score
Aaa	= 1
Aa	> 1 < 4.5
A	>= 4.5 < 7.5
Baa	>= 7.5 < 10.5
Ba	>= 10.5 < 13.5
B	>= 13.5 < 16.5
Caa	>= 16.5

Sample Calculation

	Rating	Rating Score	% of Total	Factor Score
Factor 1: Sustainable Profitability				
Sub-Factor 1	Aa	3	15%	0.5
Sub-Factor 2	Baa	9	5%	0.5
Factor 2: Regulatory Support				
Sub-Factor 3	Baa	9	10%	0.9
Factor 3: Ring Fencing				
Sub-Factor 4	Aaa	a	10%	0.1
Factor 4: Financial Strength and Flexibility				
Sub-Factor 5	A	6	15%	0.9
Sub-Factor 6	Aaa	1	15%	0.2
Sub-Factor 7	A	6	15%	0.9
Sub-Factor 8	A	6	15%	0.9
			100%	4.8
				= A1

If an LDC'S sub-factors sum to a score of 4.8, as shown above, an overall rating of A1 would be assigned. On this scale, a lower score indicates a stronger credit profile than a higher score. If the LDC's sub-factors sum to a total score of 9.0, an overall rating of Baa would be assigned. The LDC would be considered to have an average Baa2 rating profile because it falls in the middle of that category range.

In this methodology we cover 30 gas utility companies. After placing these companies through the rating factor grid,

- 7 companies (23%) map to their assigned ratings
- 14 companies (47%; 70% cumulatively) fall within one notch of their existing ratings.
- 7 companies (23%; 93% cumulatively) have indicated ratings that are within two notches higher or lower than actual ratings
- All but two companies have actual ratings that fall within two notches of their ratings on the grid, with two companies' ratings — those of South Jersey Gas and Boston Gas — falling within three and four notches, respectively, outside of their factor summaries.[6]

South Jersey Gas currently has an assigned rating of Baa2, although the Moody's methodology suggests an A2 rating (reflecting, primarily, that recent past performance may differ from future results). When one factors the company's recent rate case capitalization assumptions with the appropriate adjustments made by Moody's, leverage rises, retained cash flows decline (on account of higher dividend payouts) and coverage ratios are reduced. The company remains solidly in the investment grade category. However, the financial metrics for this company are currently in transition as implied by the methodology and the ratings based on recent historical data may not be applicable for the future.

Boston Gas is rated A2 senior unsecured compared to the model rating of Baa3. This reflects the results of push-down accounting relating to KeySpan's acquisition of Eastern Enterprises, whereby a portion of the acquisition debt and goodwill issued by the parent was allocated to Boston Gas. Additionally, as KeySpan is currently under review for possible downgrade, following the announcement that it is being acquired by National Grid Plc, a UK gas and electricity transmission business, in a transaction valued at $7.3 Billion (£4.2 Billion). The transaction may put pressure on the regulated subsidiary to support the additional debt.

While there may be outliers from time to time under the gas LDC rating methodology, the vast majority of the companies rated by Moody's do fall within the two rating notches targeted by this methodology, and their credit ratings could be explained by the relevant factors. At any given time, we could assume that one or more issuers are in a state of transition and may therefore find themselves positioned as outliers relative to their assigned ratings when compared against the ratings implied under the gas LDC methodology (i.e. the deviations are either higher or lower by more than the two desirable notches).

6. *See Appendix C for Summary Chart on Moody's Public Rating versus Indicated Model Rating.*

Regulatory Support	Regulatory Support and Relationship	10.0%	10.0%	Exceptional Proactive Support by Utility Commission to allow LDCs to timely adjust rates to cover all costs of service; Utility commission always willing to help LDC establish a cooperative framework for discussions, hearings and implementation of better rate design to help LDCs' shareholders and consumers alike. Utility Commission grants all rate design features to allow LDC to recover costs on a complete and timely basis.	Very Good Proactive Support by Utility Commission to allow LDCs to timely adjust rates to cover all costs of service; Utility commission highly willing to help LDC establish a cooperative framework for discussions, hearings and implementation of better rate design to help LDCs' shareholders and consumers alike. Rate design is near "bulletproof" cover for LDC risks. Requested rate increases tend to be approved in less than 9 months.	Good Support by Utility Commission to allow LDCs to amend rate designs. Company gets good support in proposing new solutions to deal with common utility problems such as conservation and weather variables; Differences between LDCs and utility commission are likely to be resolved. Rate filings tend to be approved under 12 months.	Reasonable support from Utility Commission to allow LDCs to recoup allowed expenses; Company gets some support in proposing new solutions to deal with common utility problems such as conservation and weather issues; Differences between LDCs and Utility Commission are reasonably resolved in a timely manner and rate cases tend to be approved in 12 – 15 months with at least 50% of LDC's target requests being granted.	Inadequate support from Utility Commission to allow LDCs to recoup allowed expenses; Utility commissioner and/or staff tends to play the role of "consumer advocate" that often counters proposals or initiatives advanced by the LDC. Cases often take over 15 months to resolve or LDC is frozen out of rate filings for over 18 months.	Inadequate support from Utility Commission to allow LDCs to recoup allowed expenses; Utility commissioner often plays the role of "consumer advocate" that tends to counter proposals or initiatives advanced by the LDC; Company is seldom involved with working on special task forces to deal with issues of rising account delinquencies or educating customers on conservation or warm weather issues. Utility suffers from increasing regulatory lag and lacks rate relief necessary to earn allowed ROE.	Inadequate and weak support from Utility Commission to allow LDCs to recoup allowed expenses. Utility commissioner always plays the role of "consumer advocate" that tends to counter proposals or initiatives advanced by the LDC; Company is hardly ever involved with working on special task forces to deal with issues of rising concern to utility or customers. Unsupportive commission/state legislature or consumer base. Utility can't earn allowed ROE.

Good ring-fencing provisions; Utility and Non-Utility are unlikely to commingle funds; Separate utility money pool or utility accounts; Inter-company loans not permitted between utility and non-utility; Utility dividend payment to parent unlikely to be allocated to non-utility.	Reasonable ring-fencing provisions; Utility and Non-Utility may need to commingle funds via consolidated corporate money pool; Bond indentures or bank credit agreements may reasonably restrict the utility from financial dealings with non utility; Inter-Company loans between utility and non-utility rare.	Inadequate ring-fencing provisions; Utility often participates in corporate cash money pool that includes non-utility and funds are often commingled; Regulators usually do not have a requirement that LDCs remain investment grade. Bond indentures or bank credit agreements may not restrict the utility financial dealings with non- utility.	Inadequate ring-fencing provisions; Utility often participates in corporate cash money pool that includes non-utility and funds are generally commingled; No requirement for LDCs to remain investment grade. Bond indentures or bank credit agreements usually do not restrict the utility financial dealings with non- utility. Inter-company loans between utility and non-utility common place.	Inadequate and weak ring-fencing provisions; Utility and Non-Utility generally always commingle funds; No requirement for LDCs to remain investment grade; Bonds indentures/ bank agreements never restrict utility financial dealing with non-utility. Inter-company loans between utility and non-utility are common place; Utility dividends to parent may fund non-utility needs.
				Corporate Governance protecting utility interests which are treated as core operation.	Very Good Corporate Governance. May lack formal regulatory or creditor leverage restrictions or IG requirement for utility, but company has strong policy of ring-fencing utility.	Good Corporate Governance of utility	Satisfactory Corporate Governance. Gas utility contributes less than 90% of consolidated group EBIT and may not be primary growth engine.	Inadequate Corporate Governance protection for utility as stand-alone entity.	Inadequate Corporate Governance for utility as a stand alone entity.	Inadequate and weak Corporate Governance of utility interests.

Appendix D

SUMMARY OF NON-FINANCIAL LDC SUB-FACTORS

1. **Regulatory Support & Relationship**: While factor No. 1 measures the adequacy and effectiveness of the LDC's business model, this factor measures both the **ability** and **willingness** of the utility regulatory commission to grant the necessary support and protection that the LDC requests in its business plans. The utility commission must be willing to help the LDC establish a cooperative framework for discussions, hearings and staff relations with its indigenous utilities as well as have the state constitutional powers to put the necessary regulations or rate designs in place. While the LDC is interested in obtaining flexibility in regulatory growth and risk protection, the commission is usually focused on ensuring a stable utility operation with reliable customer service under reasonable prices. Questions to consider include
   a. Does the Company have good working relationship with the state regulators to recoup allowed expenses and the necessary trust of its regulators that it is doing the right thing for its customers and shareholders alike?
   b. Does the Company maintain an active dialogue with the commissioners and staff in discussing and proposing new solutions to common utility problems and working on special task forces to deal with common industry issues of rising account delinquencies as gas shortages rise and prices increase, or in educating customers as to gas conservation or safety?
   c. What is the role of the commission staff, to serve as a technical advisor to the utility commission in facilitating constructive discussions with the company or does it play the role of "consumer advocate" that tends to counter proposals or initiatives advanced by the LDC in an adversarial atmosphere for dispute resolutions.
   d. How are differences between the LDC and its utility commission typically resolved, do they have a "settlement" approach where various interveners and interested parties are brought together for amicable solutions or do they resort to court actions and counter-actions to achieve their ends?
5. **Ring Fencing Quality**: We find that either regulators or creditors or the companies themselves impose certain ring-fencing parameters on the financial operations of the LDCs. Generally, ring-fencing is a desirable attribute as the utility is assured a certain financial insulation from the non-utility operations of the parent company and is not susceptible to supporting the business of its non-utility affiliates. The greater the degree of ring-fencing, the more separated is the utility from its non-utility affiliates. The strongest ring-fencing requirements tend to come from legislative statutes and regulators, followed by bond indentures and bank creditors. Occasionally, LDCs have self-imposed guidelines that could be just as rigid as those regulated, but this would depend on the analysts' confidence in the utility's strict adherence to its own firewall policies and practices. A utility's self-imposed restrictions on its own operations and its attempts at insulating itself from other non-regulated affiliates could also be evident in its corporate governance policies and practices. Issues to consider include
   a. Are inter-company loans or advances permitted between utility and non-utility operations of the same corporate family?
   b. Does the utility participate in a corporate cash money pool that includes non-utility subsidiaries, such that it is possible for the utility to deposit its surplus funds in general corporate money pool which ends being used by the non-utility affiliates for their WC needs?
   c. Does the utility dividend payment to its parent (perhaps in excess of what the parent needs to pay public shareholders) have a portion that ends up being allocated to non-utility affiliates for their operating or investment needs?
   d. Do the regulators stipulate maximum leverage ratios for the LDC or have a requirement that the LDC remain investment-grade in order to preserve its service franchise?
   e. What is the quality of the LDC's corporate governance?

APPENDIX A	RESUME	
APPENDIX B	EFFECT OF DEBT ON THE COST OF EQUITY	

I. INTRODUCTION AND SUMMARY

A. INTRODUCTION

Q1. Please state your name, address and position.

A1. My name is Michael J. Vilbert, and I am a Principal at *The Brattle Group*, 44 Brattle Street, Cambridge, MA 02138

Q2. Did you previously file testimony in this proceeding?

A2. No, I am adopting the Direct Testimony of Joel M. Reiker ("Reiker Direct") on behalf of California-American Water Company ("California-American" or the "Company") regarding return on equity that the Company should be allowed an opportunity to earn. He recommends a return on equity of 11.5 percent for a capital structure with 42 percent equity. I fully endorse that recommendation.

Q3. What is the purpose of your rebuttal testimony?

A3. I have been asked by California-American to respond to the Testimony of Mr. Cleason Willis ("Willis Testimony") on behalf of the Division of Ratepayer Advocates of the California Public Utilities Commission regarding the Willis Testimony's recommended return on equity for the Company. I have also been asked to respond to the Willis Testimony's criticism of the Reiker Direct.

B. SUMMARY

Q4. Please summarize your rebuttal testimony.

A4. This rebuttal testimony focuses on several topics stemming from the Willis Testimony. First, the Willis Testimony recognizes the importance of financial risk as a determinate of the cost of equity,[1] but makes no adjustment in the recommended return on equity based upon the higher financial risk of California-American compared to the companies in the

[1] Willis Testimony, p. 3-1.

water sample. If the Willis Testimony had recognized the differences in financial risk, the estimated return on equity would have been comparable to the 11.5 percent requested by the Company. Second, and most important, setting the allowed return on equity at 11.5 percent provides an overall cost of capital equal to the overall cost of capital authorized recently for other California water utilities, as demonstrated below.

II. ALLOWED RETURN ON EQUITY AND THE NEED FOR CAPITAL INVESTMENT IN THE WATER INDUSTRY

Q5. The Willis Testimony recommends that California-American be allowed an opportunity to earn a return on equity of 9.96 percent on a regulatory capital structure with 41.56 percent equity. Do you have any general comments?

A5. Yes. The Willis Testimony estimates an average of 9.41 percent cost of equity using the DCF model and an average of 10.51 percent using the risk positioning model[2] but makes no adjustment to the models' estimates even though the sample companies' average book-value capital structures average 53.21 percent equity compared to California-American's 41.56 percent[3] as displayed in Table 2-1 of the Willis Testimony and in Table 1 below. The difference in market-value capital structures is even larger as shown in Table 2.

Table 1: Water Sample Book Value Capital Structures

Company	2006	2005	2004	2003	2002	Company Average
American States Water Co	49.5%	48.8%	49.0%	44.3%	45.5%	47.4%

SJW Corp	58.2%	57.4%	56.2%	54.3%	57.2%	56.7%
AVERAGE	**52.3%**	**49.6%**	**49.9%**	**47.6%**	**46.6%**	**49.2%**

Source: End-of-year book values obtained from Bloomberg on April 9, 2007.

[2] Willis Testimony, p. 2-8, Table 2-8.

[3] California-American's equity percentage in its capital structure for 2008 is 41.84 percent. I use the 41.84 percent equity ratio in the analysis below.

Table 2: Water Sample Market Value Capital Structures

Company	2006	2005	2004	2003	2002	Company Average
American States Water Co	66.9%	62.4%	57.9%	54.9%	54.8%	59.4%
Aqua America Inc	73.9%	76.2%	71.1%	70.0%	64.3%	71.1%

SJW Corp	83.0%	72.2%	66.6%	62.3%	66.0%	70.0%
AVERAGE	**71.8%**	**68.9%**	**67.5%**	**64.7%**	**61.8%**	**66.9%**

Source: End-of-year book values and market prices obtained from Bloomberg on April 9, 2007.

Q6. Does the Willis Testimony's justification for not recognizing the difference in financial risk make sense?

A6. No. The Willis Testimony claims that "Cal Am has managed to maintain a good credit rating and does not appear to have any problem attracting capital. Furthermore, maintaining their current level of leverage in their capital structure is a decision under the company's management's control."[4] The first statement is misleading and the second is true, but should not affect the overall return earned by the Company.

First, as the Willis Testimony acknowledges California-American does not have a credit rating nor does it issue its own debt. Instead, it relies upon investment from its parent company, American Water Company, who uses American Water Capital Corporation as its source of investment funds. Although American Water Capital currently has an A- credit rating, that credit rating cannot be sustained if each of American Water's subsidiaries is regulated as if there is no need to provide a rate of return on equity consistent with an A- rating.[5] If the rating is to be sustained, each subsidiary must provide support for the rating. As noted in the Willis Testimony, the forecast cost of debt for California-American is *less* than the DRI forecast cost of debt for A-rated utilities.[6]

[4] Willis Testimony, p. 3-3.

[5] The median return on book equity for A-rated utilities is 10.8 percent on a median equity ratio of 46.2 percent. See Standard & Poor's, *Corporate Ratings Criteria 2006*, p. 43.

[6] Willis Testimony, p. 3-4.

This is clearly in the interest of the customers, but this benefit is only possible if a strong credit rating is maintained by the entity issuing the debt.

Second, California-American has substantial investment needs that are necessary to maintain and improve the water infrastructure in its service territory, as well as comply with various government mandates and regulations. California-American's source of funds is its parent company, American Water, and California-American's request for investment funds is combined with the requests from the other American Water subsidiaries before an allocation is made of the available investment funds. To some extent the investment decisions by the parent will take into consideration the allowed return that is expected to be earned on those funds. Discretionary investment is likely to be lower for those subsidiaries receiving a lower allowed return on a risk-adjusted basis.

Third, as demonstrated below, California-American's request for 11.5 percent return on equity is consistent with the overall returns on capital recently awarded to other water utilities in California. The only difference is that California-American has less equity in its capital structure than the other utilities, but customers would pay no more for capital on average than they pay in other water districts. Note that this point is not a premium for differences in financial risk between the sample companies and California American, but merely a request to earn the same overall rate of return on investment as has been allowed for other California water utilities.

Q7. The Willis Testimony points out that California-American's equity thickness is a decision under the control of the Company and therefore no adjustment in the allowed return on equity is warranted? How do you respond?

A7. The capital structure of California-American is under the control of American Water's management, but that fact does not justify ignoring differences in financial risk. A company's capital structure at any point in time is a function of many factors, but capital structure does not affect the overall risk of the assets. Variations in capital structure merely result in a different allocation of those risks between debt and equity holders.

Ignoring differences in capital structure results in unequal treatment of similarly situated companies as demonstrated in *Section IV* below.

Q8. If the Willis Testimony had recognized the differences in financial risk between the sample companies and California-American, what would the model estimates have been?

A8. I will first illustrate the method I use to recognize the differences in financial risk, and then I will present the results using the Willis Testimony cost of equity estimates and the average capital structures of the sample companies.

The Reiker Direct used a financial risk adjustment based upon an article by Professor Hamada;[7] however, I typically use a slightly different approach to adjusting for differences in financial risk. Specifically, I use the overall after-tax weighted-average cost of capital ("ATWACC") for the sample derived from information on the estimated costs of debt and equity in the capital markets. I then determine the return on equity at the regulated company's capital structure that would provide the same ATWACC. This is the approach I use to illustrate the results from the Willis Testimony's cost of equity estimates if differences in financial risk had been recognized. Table 3 below shows the ATWACC resulting from the sample estimates provided in the Willis Testimony.

Q9. Should financial risk for the sample companies be measured on book-value or market-value capital structures?

A9. As discussed in Appendix B, the appropriate measure of financial risk of the sample is the market-value capital structure. However, in this case, I demonstrate in the tables below that even if only the differences in book-value capital structures were recognized, an 11.5 percent return on equity for California-American's would be justified.

[7] Reiker Direct, pp 34-35. Note that the Reiker Direct uses market value capital structure information to adjust for differences in financial risk.

Table 3: ATWACCs using Return on Equity Estimates from the Willis Testimony

	Willis Testimony's Cost of Equity [1]	Common Equity Equity Ratio [2]	Cost of Preferred Equity [3]	Preferred Equity Ratio [4]	Cost of Debt [5]	Debt Ratio [6]	American's Income Tax Rate [7]	Overall After-Tax Cost of Capital [8]

Q10. Please describe the results displayed in Table 3 and in Table 4.

A10. Table 3 displays the calculation of the ATWACC for the water sample based upon the return on equity calculations in the Willis Testimony for the DCF and risk positioning models. It presents the results using both the market value and the book value capital

structures of the water sample companies. Table 4 uses the ATWACC calculated in Table 3 to determine the risk-adjusted return on equity inherent in the water sample information utilized in the Willis Testimony. As Table 4 illustrates, considering financial risk results in return on equity estimates that exceed California-American's requested 11.5 percent for all cases except for the DCF model using book value weights.

Q11. Can you provide a simple example of the calculation of the cost of equity consistent with the market-determined estimate of the sample's average overall cost of capital displayed in Table 3 and Table 4?

A11. Yes. Consider the following equation to calculate the ATWACC:[8]

$$ATWACC = r_D \times (1 - T_C) \times D + r_E \times E \qquad (1)$$

where r_D = market cost of debt,
r_E = market cost of equity,
T_C = corporate income tax rate,
D = percentage of debt in the capital structure, and
E = percentage of equity in capital structure.

The cost of equity consistent with overall cost of capital estimate (ATWACC) from the sample, the market cost of debt and equity, the marginal corporate income tax rate and the amount of debt and equity in the capital structure can be determined by solving equation (1) for r_E.

Q12. Please summarize your comments on the Willis Testimony's recommended return on equity at California-American's regulatory capital structure.

A12. The Willis Testimony's recommendations are consistent with the return on equity recommended in the Reiker Direct *when* differences in financial risk are considered. The Willis Testimony recognizes the importance of financial risk, but the reasons offered for not making any adjustment to the returns estimated from market data do not stand up to

[8] Note that this equation assumes that only debt and equity are in the capital structure, but it is simple to add preferred equity to the equation.

closer review. The financial risk of the sample companies is lower than for California-American and that difference in financial risk should be recognized.

The Company does not have a stand-alone credit rating and does not issue its own debt but relies on the financial strength of American Water to acquire the investment funds it needs. American Water will not be able to maintain its A- credit rating if its subsidiaries are not authorized a rate of return that would justify that rating. If American Water's credit rating weakens, it will cost customers more as new debt is issued in the future.

III. RISK OF THE WATER INDUSTRY

Q13. Has the risk of water utilities increased recently?

A13. In general, yes. While I recognize that water utilities traditionally have been viewed as relatively safe compared to many other industries, the risk of the water industry is increasing. Publicly traded water utilities in the U.S. generally have good credit ratings, but Moody's Investors Service ("Moody's") and S&P note the need for significant capital expenditure, the costs of complying with environmental and security regulation as sources of risk.[9] Fitch notes that the debt ratios are increasing.[10] At the same time the regulatory requirements for the water industry are evolving.[11] This increase in risk is documented by the increasing average estimated betas by *Value Line Investment Survey* ("*Value Line*") for the water sample which is shown below in Figure MJV-R1. *Value Line's* estimated betas for the water utility companies covered as of the last report for each year since 1995 have increased from an average of about 0.50 in 1995 to an average of about 0.70 in 2006. *Value Line's* beta estimates demonstrate that the average risk of the industry appears to be increasing.

[9] Moody's *Credit Risks Are Increasing for U.S. Investor Owned Water Utilities*, Special Comment, January 2004, S&P *Key Rating Factors for Water Companies Around the World*, July 17, 2006.

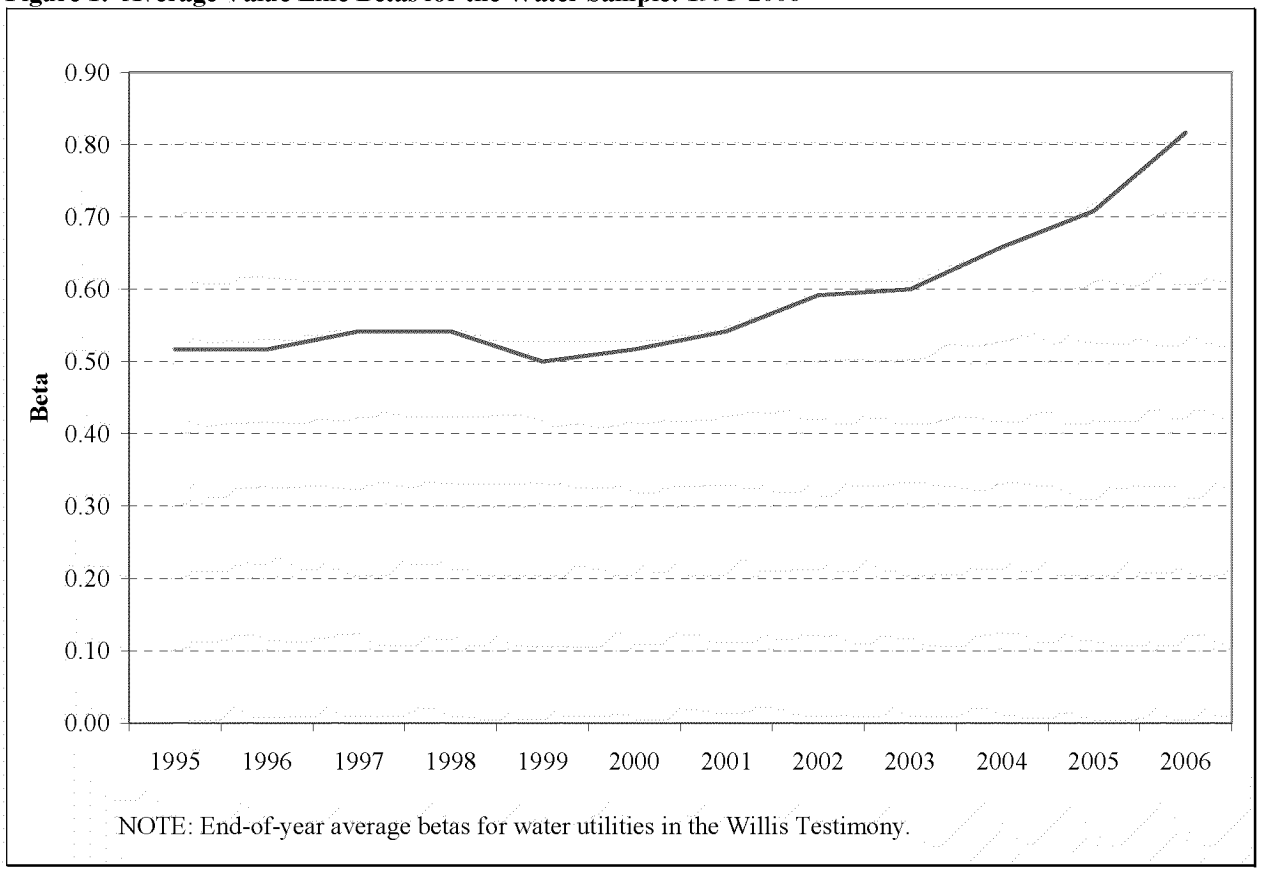
[11] For example, the Ground Water Rule was signed in November 2006.

Figure 1: Average Value Line Betas for the Water Sample: 1995-2006



Q14. The market data seem to suggest that the water industry's risk has increased dramatically compared to other regulated industries. Do you have any concerns with the market information?

A14. Yes. The data from the capital markets are suggesting that the cost of capital for the water industry has substantially over the last few years, but I believe that the data should be interpreted with some caution. The water sample consists of companies that are smaller in general than the companies in the Reiker Direct's gas local distribution sample and electric sample. In addition, some of the companies in the water sample have recently been involved in mergers and acquisitions. These factors may be affecting the cost of capital estimates for the sample, and I believe that this is one reason that the Reiker Direct reported results for two other samples to serve as a check on the results from the water sample.

Q15. What do you recommend when interpreting the results from the water sample?

A15. In the past whenever any sample's cost of capital estimates seem to be either unusually high or low, I have considered the relative risk of the sample to that of other regulated industries as a check on the results. In this case, the comparison warrants caution in interpreting the resulting cost of equity estimates from a fully consistent application of financial principles to the water sample's results. In other words, I believe that the estimates in Table 4 above indicating a return on equity of more than 13 percent for California-American after recognition of differences in financial risk may not be completely reliable. However, I also believe that American-Water's requested 11.5 percent return on equity is fully justified by the evidence from all of the samples and from comparison to the returns allowed for other California water utilities as described in *Section IV* below.

Q16. Previously you stated that the water industry needs to undertake substantial capital expenditures going forward. Would you please elaborate?

A16. Yes. The Environmental Protection Agency ("EPA") has indicated that the water industry needs to invest capital of about $224 billion over the next two decades to meet the nation's need for clean drinking water and for waste water disposal.[12] Indeed, the American Society of Civil Engineers has estimated that drinking water infrastructure needed in California will be $17.5 billion over the next two decades, with an additional $14.4 billion for waste water infrastructure.[13] Similarly, *Value Line* notes the need for investment totaling "hundreds of millions of dollars over the next two decades" by the utilities it follows in the water industry as the EPA continues to increase its water purification standard. In addition, as noted by *Value Line*, the need to provide security against acts of terrorism and to replace aging water mains will add to the required investment.[14] This is a substantial investment requirement for a group of companies that

[12] www.epa.gov/waterinfrastructure/infrastructuregap.html

[13] See, 2005 Report Card for America's Infrastructure, available at www.asce.org.

[14] *Value Line Investment Survey*, Water Utility Industry, April 7, 2007, p. 1419.

Value Line estimates to have an annual profit of about $150 million.[15] *Value Line* also notes that "[m]any of the smaller companies in the industry do not have the resources to meet the capital expenditures that they are being saddled with. Some are deciding to merge with larger, more financially sound enterprises."[16]

Q17. Is the need for investment in California's water infrastructure recognized by the Commission?

A17. Yes. The Commission's *Water Action Plan* recognizes the need for and importance of additional investment in water infrastructure, as well as the goal of maintaining the highest standards or water quality.[17] Water conservation can play a role in reducing the total amount of water infrastructure investment required, but conservation alone will not eliminate the need for substantial investment going forward.

Q18. The Willis Testimony suggests that regulatory risk has virtually been eliminated for California American water.[18] Do the Commission's regulatory mechanisms result in a reduction in the cost of capital for California-American?

A18. The total risk faced by equity holders in a regulated company consists of business risk, financial risk and regulatory risk. A portion of total risk is can be avoided by investors through diversification and therefore that portion is not part of the risk reflected in the cost of capital. Only the part of total risk which is non-diversifiable affects the cost of capital. Decisions by the regulator can mitigate the effects of business and regulatory risk on the regulated company, but regulatory actions can also increase risk. To the extent that regulatory actions have truly reduced business and regulatory risk without creating new risks, the overall cost of capital would be reduced. However, it must also be kept in mind that although actions by regulators can indirectly affect stock prices, they cannot directly affect the prices investors will pay for a company's equity. This means that some risk will remain. To the extent that the proposed Water Revenue Adjustment

[17] *Water Action Plan*, California Public Utilities Commission, December 15, 2005.

[18] Willis Testimony at 3-3.

Mechanism is designed to remove weather related risk for California-American, it is important to note the weather risk is normally a diversifiable risk (i.e., investors can avoid it), and therefore, does not affect the cost of capital. Weather risk is part of total risk, and it does affect the likelihood that the company will earn its allowed rate of return, but because weather risk is diversifiable, it is not part of the risks affecting the cost of capital.[19] Removing weather risk would not therefore reduce the company's cost of capital. Finally, none of these actions removes financial risk although the risk to be shared between debt and equity may have been reduced.

Q19. What are the implications of the need for infrastructure investment and the increasing risks for the industry on the cost of capital?

A19. Financing the needed infrastructure investment means that the industry must attract investor capital. Investors choose to fund investments for which the expected return on their capital corresponds to the risk of the investment. The return on equity that investors require increases with the risks inherent in the investment. Maintaining a financially strong company will be essential if California-American is to acquire the capital it needs to fund the necessary investments to provide the high quality of service to its customers that is envisioned in the Commission's *Water Action Plan*.

IV. COMPARISON OF ALLOWED RETURNS FOR CALIFORNIA'S WATER UTILITIES

Q20. What does this section address?

A20. This section addresses the importance of considering capital structure when establishing the allowed return for regulated companies. Table 5 below shows the ATWACCs resulting from the allowed returns on equity and capital structures for a group of California water utilities. The ATWACC is calculated using formula (1) above. Table 5 shows that the allowed overall cost of capital (i.e., ATWACC) differs substantially

[19] The *cost of capital* is *the expected rate of return in capital markets on alternative investments of equivalent risk* and therefore an ex ante concept.

company-to-company even though the overall total business of the assets would be expected to be the same because the assets are all for the purpose of providing regulated water service.

Table 5: ATWACC's Derived from Approved Rates of Return for California Water Utilities

	Allowed ROE [1]	Equity Ratio [2]	Cost of Debt [3]	Debt Ratio [4]	California's Income Tax Rate [5]	Overall After-Tax Cost of Capital [6]
Privately Owned:

[5]: California's 2007 marginal corporate tax rate for firms with income greater than $18.3 MM.
[6]: [1] x [2] + ([3] x [4] x (1 - [5])).

Q21. What is the implication of Table 5?

A21. The difference in the overall cost of capital allowed for the various water utilities in California means that $1,000 invested by one utility costs customers more (provides more

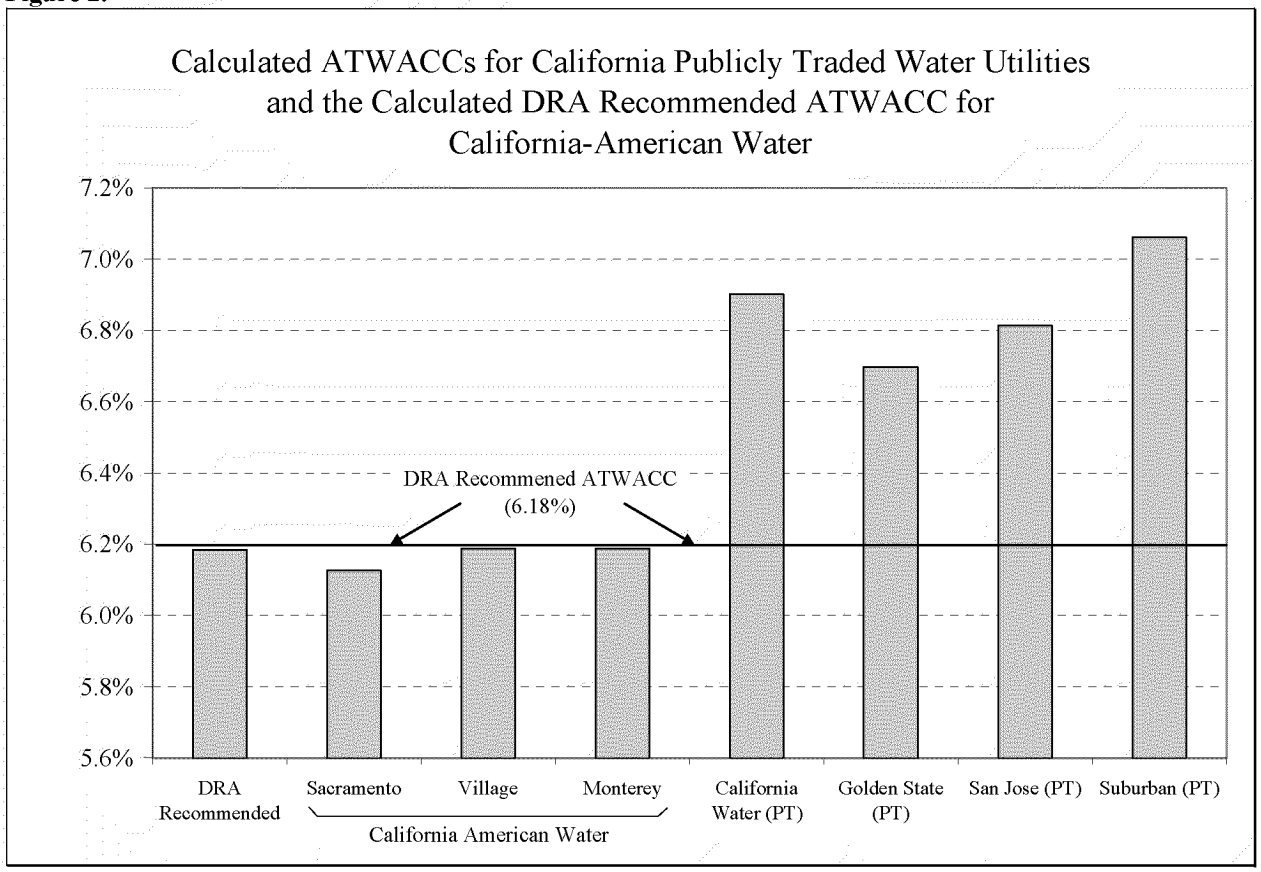
return to investors) than for another utility. For example, a privately owned water utility receives $76.20 after-tax for every $1,000 of investment in rate based whereas the California-American districts receive only $61.70 after-tax.[20] Note that the difference in the ATWACC is not due to differences in the cost of debt because this analysis assumes that each company has the same cost of debt. The difference is solely due to differences in the allowed returns on equity and the allowed capital structures. In other words, if capital structure is not considered when the allowed return on equity is established, companies that are otherwise very similar end up with different returns on investment.

Q22. Some of the companies in Table 5 are privately owned water companies. If only publicly traded companies are considered, what are the results?

A22. The results change somewhat because the allowed ATWACCs for the privately owned companies are higher on average than for the publicly traded companies, but the variation in overall cost of capital is still evident as shown in Figure 2 below.

[20] The cost per $1,000 of investment is estimated as the product of the ATWACC from Table 4 times $1,000.

Figure 2:



Note that California-American's water districts have been allowed an average ATWACC of 6.17 percent compared to an average of 6.87 percent for all other publicly traded water companies (See Table 5 above). The Willis Testimony's recommendation of 6.18 percent is comparable to that which has been allowed for the California-American districts in the past, but it is also substantially below the ATWACCs allowed for all of the other companies.

Q23. If California-American were allowed an ATWACC equal to the average of the other publicly traded companies, what would the allowed return on equity need to be?

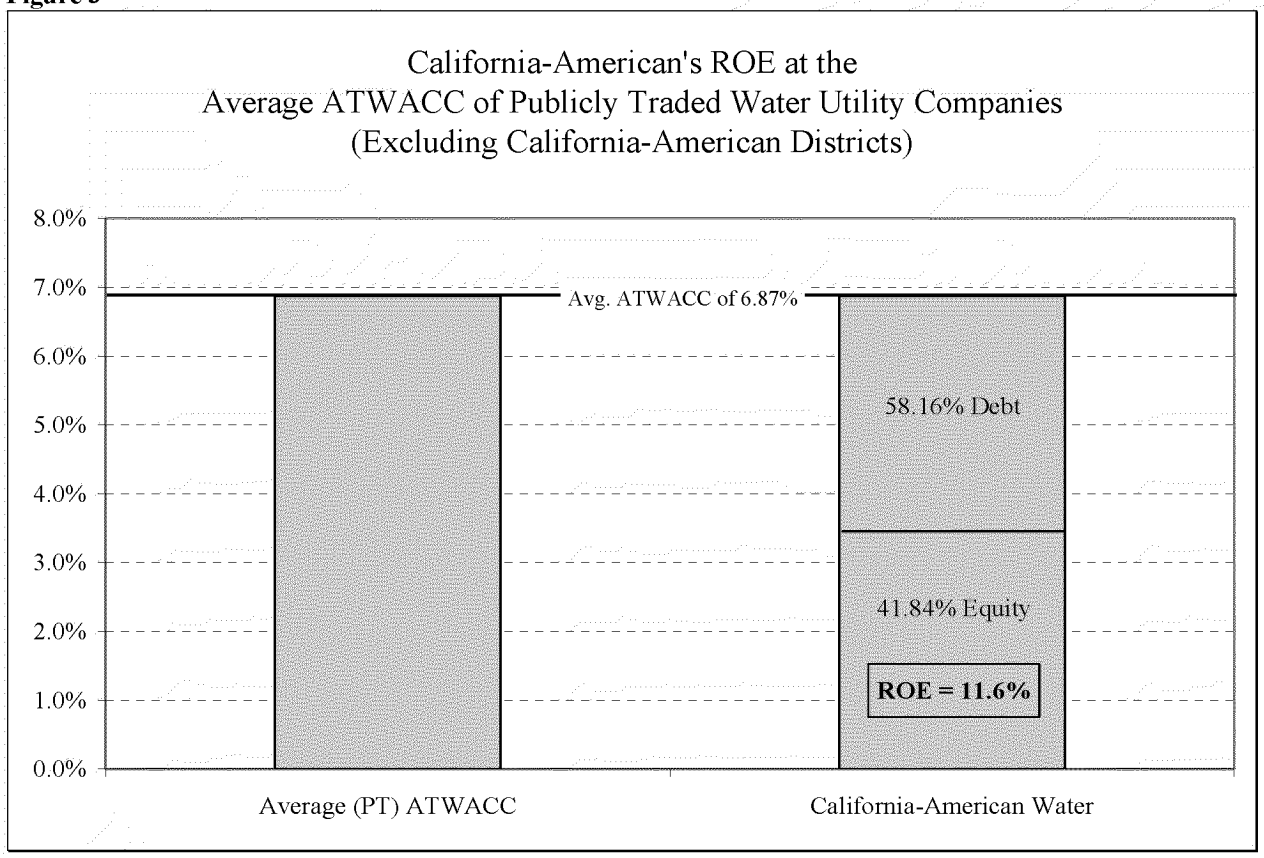
A23. If California-American were allowed an ATWACC of 6.87 percent, the allowed return on equity would need to be 11.6 percent which is only slightly higher than the 11.5 percent requested by the Company. In other words, if the effect of differences in capital structure on overall allowed returns are considered, an allowed return on equity of 11.5 percent would result in an overall cost of capital for California-American that is equal to

that has been allowed for other similarly situated water utilities in California. The 11.6 percent rate of return is calculated as follows (using the same notation as in equation 1 above):

$$\begin{aligned} \text{Return on Equity} &= \frac{ATWACC - r_D \times (1 - T_C) \times D}{E} \\ &= \frac{(0.0687 - 0.059 \times (1 - 40.7\%) \times 58.16\%}{41.84\%} \\ &= 11.6\% \end{aligned} \qquad (2)$$

This calculation is illustrated in Figure 3 below.

Figure 3



Q24. If California-American were allowed an 11.6 percent return on equity, would its customers pay the same cost per $1,000 of investment in rate base as the customers of the other water utilities?

A24. In general, no, because the calculation of an 11.6 percent return on equity assumes that the cost of debt is the same for all of the water utilities. To the extent that American Water can issue less costly debt, allowing 11.6 percent return on equity for California-American would still result in a lower cost to customers per $1,000 of investment than for the other water utilities. The comparisons in this section are merely to show what the return on equity would have to be in order for California-American to earn the same overall return on investment as other California utilities. Actual costs to customers would differ depending upon the actual cost of debt as well as other costs for each utility.

V. CONCLUSIONS

Q25. What are your conclusions regarding the Willis Testimony?

A25. Although the Willis Testimony implements the DCF and risk positioning models differently than I do, the Willis Testimony's cost-of-equity estimates from the water sample are consistent with the California-American's request for an 11.5 percent return on equity under two separate measures of comparability. The first measure is to recognize the differences in financial risk between the sample companies and California-American. When adjusted for differences in financial risk, the estimated returns from the Willis Testimony exceed the 11.5 percent request as shown in Table 4 above. The second measure is to compare the overall cost to customers of the allowed returns on other California water utilities. If California-American were authorized an overall return equal to that allowed other water utilities, an 11.6 percent return would be required as shown in Figure 3 above.

APPENDIX A

RESUMÉ

MICHAEL J. VILBERT **PRINCIPAL**

Michael Vilbert is an expert in cost of capital, financial planning and valuation who has advised clients on these matters in the context of a wide variety of investment and regulatory decisions. He received his Ph.D. in Financial Economics from the Wharton School of the University of Pennsylvania, an MBA from the University of Utah, an M.S. from the Fletcher School of Law and Diplomacy, Tufts University, and a B.S. degree from the United States Air Force Academy. He joined The Brattle Group in 1994 after a career as an Air Force officer, where he served as a fighter pilot, intelligence officer, and professor of finance at the Air Force Academy.

REPRESENTATIVE CONSULTING EXPERIENCE

- In a securities fraud case, Dr. Vilbert designed and created a model to value the private placement stock of a drug store chain as if there had been full disclosure of the actual financial condition of the firm. He analyzed key financial data and security analyst's reports regarding the future of the industry in order to recreate pro forma balance sheet and income statements under a variety of scenarios designed to establish the value of the firm.

- For pharmaceutical companies rebutting price-fixing claims in antitrust litigation, Dr. Vilbert was a member of a team which prepared a comprehensive analysis of industry profitability. The analysis replicated, tested and critiqued the major recent analyses of drug costs, risks and returns. The analyses helped develop expert witness testimony to rebut allegations of excess profits.

- For an independent electric power producer, Dr. Vilbert created a model that analyzed the reasonableness of rates and costs filed by a natural gas pipeline. The model not only duplicated the pipeline's rates, but it also allowed simulation of a variety of "what if" scenarios associated with cost recovery under alternative time patterns and joint cost allocations. Results of the analysis were adopted by the intervenor group for negotiation with the pipeline.

- For the CFO of an electric utility, Dr. Vilbert developed the valuation model used to support a stranded cost estimation filing. The case involved a conflict between two utilities over the responsibility for out-of-market costs associated with a power purchase

contract between them. In addition, he advised and analyzed cost recovery mechanisms that would allow full recovery of the stranded costs while providing a rate reduction for the company's rate payers.

- Dr. Vilbert has assisted in the preparation of testimony and the development of estimation models in numerous cost of capital cases for natural gas pipeline, water utility and electric utility clients before the Federal Energy Regulatory Commission ("FERC") and state regulatory commissions. These have spanned standard estimation techniques (e.g., Discounted Cash Flow and Risk Positioning models). He has also developed and applied more advanced models specific to the industries or lines of business in question, e.g., based on the structure and risk characteristics of cash flows, or based on multi-factor models that better characterize regulated industries.

- Dr. Vilbert has valued several large, residual oil-fired generating stations to evaluate the possible conversion to natural gas or other fuels. In these analyses, the expected pre- and post-conversion station values were computed using a range of market electricity and fuel cost conditions.

- For a major western electric utility, Dr. Vilbert helped prepare testimony that analyzed the prudence of QF contract enforcement. The testimony demonstrated that the utility had not been compensated in its allowed cost of capital for major disallowances stemming from QF contract management.

- Dr. Vilbert analyzed the economic need for a major natural gas pipeline expansion to the Midwest. This involved evaluating forecasts of natural gas use in various regions of the United States and the effect of additional supplies on the pattern of natural gas pipeline use. The analysis was used to justify the expansion before the FERC and the National Energy Board of Canada.

- For a Public Utility Commission in the Northeast, Dr. Vilbert analyzed the auction of an electric utilities purchase power agreements to determine whether the outcome of the auction was in the ratepayers' interest. The work involved the analysis of the auction procedures as well as the benefits to ratepayers of transferring risk of the PPA payments to the buyer.

- Dr. Vilbert led a team tasked to determine whether bridge tolls were "just and reasonable" for a non-profit port authority. Determination of the cost of service for the authority required estimation of the value of the authority's assets using the trended original cost methodology as well as evaluation of the operations and maintenance budgets. Investment costs, bridge traffic information and inflation indices covering a 75 year period were utilized to estimate the value of four bridges and a passenger transit line valued in excess of $1 billion.

- Dr. Vilbert helped a recently privatized railroad in Brazil develop an estimate of its revenue requirements, including a determination of the railroad's cost of capital. He also helped evaluate alternative rate structures designed to provide economic incentives to shippers as well as to the railroad for improved service. This involved the explanation and analysis of the contribution margin of numerous shipper products, improved cost analysis and evaluation of bottlenecks in the system.

- For a utility in the Southeast, Dr. Vilbert quantified the company's stranded costs under several legislative electric restructuring scenarios. This involved the evaluation of all of the company's fossil and nuclear generating units, its contracts with Qualifying Facilities and the prudence of those QF contracts. He provided analysis concerning the impact of securitizing the company's stranded costs as a means of reducing the cost to the rate payers and several alternative designs for recovering stranded costs.

- For a recently privatized electric utility in Australia, Dr. Vilbert evaluated the proposed regulatory scheme of the Australian Competition and Consumer Commission for the company's electric transmission system. The evaluation highlighted the elements of the proposed regulation which would impose uncompensated asymmetric risks on the company and the need to either eliminate the asymmetry in risk or provide additional compensation so that the company could expect to earn its cost of capital.

- For an electric utility in the Southwest, Dr. Vilbert helped design and create a model to estimate the stranded costs of the company's portfolio of Qualifying Facilities and Power Purchase contracts. This exercise was complicated by the many variations in the provisions of the contracts that required modeling in order to capture the effect of changes in either the performance of the plants or in the estimated market price of electricity.

- Dr. Vilbert helped prepare the testimony responding to a FERC request for further comments on the appropriate return on equity for electric transmission facilities. In addition, Dr. Vilbert was a member of the team that made a presentation to the FERC staff on the expected risks of the unbundled electric transmission line of business.

- Dr. Vilbert and Mr. Frank C. Graves, also of The Brattle Group, prepared testimony evaluating an innovative Canadian stranded cost recovery procedure involving the auctioning of the output of the province's electric generation plants instead of the plants themselves. The evaluation required the analysis of the terms and conditions of the long-term contracts specifying the revenue requirements of the plants for their entire forecasted remaining economic life and required an estimate of the cost of capital for the plant owners under this new stranded cost recovery concept.

- Dr. Vilbert served as the neutral arbitrator for the valuation of a petroleum products tanker. The valuation required analysis of the Jones Act tanker market and the supply and demand balance of the available U.S. constructed tanker fleet.

TESTIMONY

Direct and rebuttal testimony before the Alberta Energy and Utilities Board on behalf of TransAlta Utilities Corporation in the matter of an application for approval of its 1999 and 2000 generation tariff, transmission tariff, and distribution revenue requirement, October 1998.

Direct testimony before the Federal Energy Regulatory Commission on behalf of Central Maine Power in Docket No. ER00-982-000, December 1999.

Direct testimony before the Alberta Energy and Utilities Board on behalf of TransAlta Utilities Corporation for approval of its 2001 transmission tariff, May 2000.

Direct testimony before the Federal Energy Regulatory Commission on behalf of Mississippi River Transmission Corporation in Docket No. RP01-292-000, March 2001.

Written evidence, rebuttal, reply and further reply before the National Energy Board in the matter of an application by TransCanada PipeLines Limited for orders pursuant to Part I and Part IV of the *National Energy Board Act*, Order AO-1-RH-4-2001, May 2001, Nov. 2001, Feb. 2002.

Written evidence before the Public Utility Board on behalf of Newfoundland & Labrador Hydro - Rate Hearings, October 2001.

Direct testimony (with Bill Lindsay) before the Federal Energy Regulatory Commission on behalf of DTE East China, LLC in Docket No. ER02-1599-000, April 2002.

Direct and rebuttal reports before the Arbitration Panel in the arbitration of stranded costs for the City of Casselberry, FL, Case No. 00-CA-1107-16-L, July 2002.

Direct reports before the Arbitration Board for Petroleum products trade in the Arbitration of the Military Sealift Command vs. Household Commercial Financial Services, fair value of sale of the Darnell, October 2002.

Direct testimony and hearing before the Arbitration Panel in the arbitration of stranded costs for the City of Winter Park, FL, In the Circuit Court of the Ninth Judicial Circuit in and for Orange County, FL, Case No. C1-01-4558-39, December 2002.

Direct testimony before the Federal Energy Regulatory Commission on behalf of Florida Power Corporation, dba Progress Energy Florida, Inc. in Docket No. SC03-___-000, March 2003.

Direct report before the Arbitration Panel in the arbitration of stranded costs for the Town of Belleair, FL, Case No. 000-6487-C1-007, April 2003.

Direct and rebuttal reports before the Alberta Energy and Utilities Board in the matter of the Alberta Energy and Utilities Board Act, R.S.A. 2000, c. A-17, and the Regulations under it; in the matter of the Gas Utilities Act, R.S.A. 2000, c. G-5, and the Regulations under it; in the matter of the Public utilities Board Act, R.S.A. 2000, c. P-45, as amended, and the Regulations under it; and in the matter of Alberta Energy and Utilities Generic Cost of Capital Hearing, Proceeding No. 1271597, July 2003, November 2003.

Written evidence before the National Energy Board in the matter of the National Energy Board Act, R.S.C. 1985, c. N–7, as amended, (Act) and the Regulations made under it; and in the matter of an application by TransCanada PipeLines Limited for orders pursuant to Part IV of the *National Energy Board Act*, for approval of Mainline Tolls for 2004, RH-2-2004, January 2004.

Direct and rebuttal testimony before the Public Service Commission of West Virginia, on Cost of Capital for West Virginia-American Water Company, Case No 04-0373-W-42T, May 2004.

Direct and rebuttal testimony before the Federal Energy Regulatory Commission, on Energy Allocation of Debt Cost for Incremental Shipping Rates for Edison Mission Energy, Docket No. RP04-274-000, December 2004 and March 2005.

Direct testimony before the Arizona Corporation Commission, Cost of Capital for Paradise Valley Water Company, a subsidiary of Arizona-American Water Company, Docket No. WS-01303A-05, May 2005.

Written evidence before the Ontario Energy Board, Cost of Capital for Union Gas Limited, Inc., Docket No. EB-2005-0520, January 2006.

Direct and rebuttal testimony before the Pennsylvania Public Utility Commission, Return on Equity for Metropolitan Edison Company, Docket No. R-00061366 and Pennsylvania Electric Company, Docket No. R-00061367, April 2006 and August 2006.

Expert report in the United States Tax Court, Docket No. 21309-05, 34th Street Partners, DH Petersburg Investment, LLC and Mid-Atlantic Finance, Partners Other than the Tax Matters Partner, Petitioner, v. Commissioner of Internal Revenue, Respondent, July 28, 2006.

Direct and supplemental testimony before the Federal Energy Regulatory Commission, Docket No. ER06-427-003, on behalf of Mystic Development, LLC on the Cost of Capital for Mystic 8

and 9 Generating Plants Operating Under an Reliability Must Run Contract, August 2006 and September 2006.

Direct testimony before the Federal Energy Regulatory Commission, Docket No. ER07-46-000, on behalf of Northwestern Corporation on the Cost of Capital for Transmission Assets, October 2006.

Direct and rebuttal testimony before the Tennessee Regulatory Authority, Case No. 06-00290, on behalf of Tennessee American Water Company, on the Cost of Capital, November, 2006 and April 2007.

Direct testimony before the Public Service Commission of Wisconsin, Docket No. 07-___, on behalf of Wisconsin Electric Power Corporation and Wisconsin Gas LLC on the Cost of Capital, May 2007.

APPENDIX B

EFFECT OF DEBT ON THE COST OF EQUITY

I. AN OVERVIEW OF THE ECONOMIC LITERATURE 1

A. TAX EFFECTS 1
1. Base Case: No Taxes, No Risk to High Debt Ratios 2
2. Corporate Tax Deduction for Interest Expense 3
3. Personal Tax Burden on Interest Expense 5

B. NON-TAX EFFECTS 7

II. EXPANDED EXAMPLE 12

A. DETAILS OF DIFFERENT LEVELS OF DEBT 12

B. THE IMPACT OF INCOME AND INTEREST 16

C. THE EFFECT OF TAXES 19

D. COMBINED EFFECTS 25

Q1. What is the purpose of this Appendix?

A1. In this appendix, I provide details on the effects of debt on the cost of equity. First, I summarize a fairly large body of financial research on capital structure. Second, I provide an extended example to illustrate the effect of debt on the cost of equity.

I. AN OVERVIEW OF THE ECONOMIC LITERATURE

Q2. What is the focus of the economic literature on the effects of debt?

A2. The economic literature focuses on the effects of debt on the value of a firm. The standard way to recognize one of these effects, the impact of the fact that interest expense is tax-deductible, is to discount the all-equity after-tax operating cash flows generated by a firm or an investment project at a weighted average cost of capital, typically known in textbooks as the "WACC." The textbook WACC equals the *market*-value weighted average of the cost of equity and the *after-tax*, *current* cost of debt. However, rate regulation in North America has a legacy of working with another weighted-average cost of capital, the *book*-value weighted average of the cost of equity and the *before-tax*, *embedded* cost of debt. To distinguish the concepts, I refer to the after-tax weighted-average cost of capital as ATWACC.

Q3. How is this section of the appendix organized?

A3. It starts with the tax effects of debt. It then turns to other effects of debt.

A. TAX EFFECTS

Q4. What are the key findings in the literature regarding tax effects?

A4. Three seminal papers are vital for this literature. The first assumes no taxes and risk-free debt. The second adds corporate income taxes. The third adds personal income taxes.

1. Base Case: No Taxes, No Risk to High Debt Ratios

Q5. Please start by explaining the simplest case of the effect of debt on the value of a firm.

A5. The "base case," no taxes and no costs to excessive debt, was worked out in a classic 1958 paper by Franco Modigliani and Merton Miller, two economists who eventually won Nobel Prizes in part for their body of work on the effects of debt.[1] Their 1958 paper made what is in retrospect a very simple point: if there are no taxes and no risk to the use of excessive debt, use of debt will have no effect on a company's operating cash flows (i.e., the cash flows to investors as a group, debt plus equity combined). If the operating cash flows are the same regardless of whether the company finances mostly with debt or mostly with equity, then the value of the firm cannot be affected at all by the debt ratio. In cost of capital terms, this means the overall cost of capital is constant regardless of the debt ratio, too.

In the base case, issuing debt merely divides the cash flows into two pools, one for bondholders and one for shareholders. If the divided pools have different priorities in claims on the cash flows, the risks and costs of capital will differ for each pool. But the risk and overall cost of capital of the entire firm, the sum of the two pools, is constant regardless of the debt ratio. Thus,

$$r_1^* = r_{A1} \qquad \text{(B-1a)}$$

where r^*_1 is the overall after-tax cost of capital at any particular capital structure and r_{A1} is the all-equity cost of capital for the firm. (The "1" subscripts distinguish the case where there are no taxes from subsequent equations that consider first corporate and then both corporate and personal taxes.) With no taxes and no risk to debt, the overall cost of capital does not change with capital structure.

This implies that the relationship of the overall cost of capital to the component costs of debt and equity is

[1] Franco Modigliani and Merton H. Miller (1958), "The Cost of Capital, Corporation Finance and the Theory of Investment," *American Economic Review*, 48, pp. 261-297.

$$r_{E1} \times \left(\frac{E}{V}\right) + r_{D1} \times \left(\frac{D}{V}\right) = r_1^* \quad \text{(B-1b)}$$

with the overall cost of capital (r^*) on the *right* side, as the *independent* variable, and the costs of equity (r_E) and debt (r_D) on the left side, as *dependent* variables determined by the overall cost of capital and by the capital structure (i.e., the shares of equity (E) and debt (D) in overall firm value (V=E+D)) that the firm happens to choose. Note that if equation (B-1a) were correct, the equation that solved it for the cost of equity would be,

$$r_{E1} = r_1^* + (r_1^* - r_D) \times \left(\frac{D}{E}\right) \quad \text{(B-1c)}$$

Note also that (D/E) gets exponentially higher in this equation as the debt-to-value ratio increases[2] i.e., the cost of equity increases exponentially with leverage.

2. Corporate Tax Deduction for Interest Expense

Q6. What happens when you add corporate taxes to the discussion?

A6. If corporate taxes exist with risk-free debt (and if only taxes at the corporate level matter, not taxes at the level of the investor's personal tax return), the initial conclusion changes. Debt at the corporate level reduces the company's tax liability by an amount equal to the marginal tax rate times interest expense. All else equal, this will add value to the company because more of the operating cash flows will end up in the hands of investors as a group. That is, if only corporate taxes mattered, interest would add cash to the firm equal to the corporate tax rate times the interest expense. This increase in cash would increase the value of the firm, all else equal. In cost of capital terms, it would reduce the overall cost of capital.

How much the value of the firm would rise and *how far* the overall cost of capital would fall would depend in part on how often the company adjusts its capital structure, but this

[2] For example, at 20-80, 50-50, and 80-20 debt-equity ratios, (D/E) equals, respectively, (20/80) = 0.25, (50/50) = 1.0, and (80/20) = 4.0. The extra 30 percent of debt going from 20-80 to 50-50 has much less impact on (D/E) [i.e., by moving it from 0.25 to 1.0] than the extra 30 percent of debt going from 50-50 to 80-20 [i.e., by moving it from 1.0 to 4.0]. Since the cost of equity equals a constant risk premium times the debt-equity ratio, the cost of equity grows ever more rapidly as you add more and more debt.

is a second-order effect in practice. (The biggest effect would be if companies could issue riskless perpetual debt, an assumption Profs. Modigliani and Miller explored in 1963, in the second seminal paper;[3] this assumption could *not* be true for a real company.) Prof. Robert A. Taggart provides a unified treatment of the main papers in this literature and shows how various cases relate to one another.[4] Perhaps the most useful set of benchmark equations for the case where only corporate taxes matter are:

$$r_2^* = r_{A2} - r_D \times t_C \times \left(\frac{D}{V}\right) \tag{B-2a}$$

$$r_2^* = r_{E2} \times \left(\frac{E}{V}\right) + r_D \times \left(\frac{D}{V}\right) \times (1 - t_C) \tag{B-2b}$$

which imply for the cost of equity,

$$r_{E2} = r_{A2} + (r_{A2} - r_D) \times \left(\frac{D}{E}\right) \tag{B-2c}$$

where the variables have the same meaning as before but the "2" subscripts indicate the case that considers corporate but not personal taxes.

Note that Equation (B-2a) implies that when only corporate taxes matter, the overall after-tax cost of capital declines steadily as more debt is added, until it reaches a minimum at 100 percent debt (i.e., when D/V = 1.0). Note also that Equation (B-2c) still implies an exponentially increasing cost of equity as more and more debt is added. In fact, except for the subscript, Equation (B-2c) looks just like Equation (B-1c).

However, whether any value is added and whether the cost of capital changes at all also depends on the effect of taxes at the personal level.

3. Personal Tax Burden on Interest Expense

Q7. How do personal taxes affect the results?

A7. Ultimately, the purpose of investment is to provide income for consumption, so personal taxes affect investment returns. For example, in the U.S., municipal bonds have lower interest rates than corporate bonds because their income is taxed less heavily at the personal level. In general, capital appreciation on common stocks is taxed less heavily than interest on corporate bonds because (1) taxes on unrealized capital gains are deferred until the gains are realized, and (2) the capital gains tax rate is lower. Dividends are taxed less heavily than interest, also, under current tax law.[5] The effects of personal taxes on the cost of common equity are hard to measure, however, because common equity is so risky.

Professor Miller, in his Presidential Address to the American Finance Association,[6] explored the issue of how personal taxes affect the overall cost of capital. The paper pointed out that personal tax effects could offset the effect of corporate taxes entirely.

Q8. Is it likely that the effect of personal taxes will completely neutralize the effect of corporate taxes?

A8. I do not believe so, although the likelihood of such a result would be increased if the current federal tax reductions on dividends and capital gains became permanent rather than expiring in 2010. However, personal taxes are important even if they do not make the corporate tax advantage on interest vanish entirely. Capital gains and dividend tax advantages definitely convey some personal tax advantage to equity, and even a partial personal advantage to equity reduces the corporate advantage to debt.

---

[5] The current maximum personal tax rate on dividend income was extended to the end of 2010 by the President on May 17, 2006. It is uncertain whether the reduced rates on dividend income will be further extended.

[6] Merton H. Miller (1977), "Debt and Taxes," *The Journal of Finance*, 32: 261-276, the third of the seminal papers mentioned earlier.

The Taggart paper explores the case of a partial offset, also. With personal taxes, the risk-free rate on the security market line is the after-personal-tax rate, which must be equal for risk-free debt and risk-free equity.[7] Therefore, the pre-personal-tax risk-free rate for equity will generally not be equal to the pre-personal-tax risk-free rate for debt. In particular, $r_{fE} = r_{fD} \times [(1-t_D)/(1-t_E)]$, where r_{fE} and r_{fD} are the risk-free costs of equity and debt and t_E and t_D are the personal tax rates for equity and debt, respectively. In terms of the cost of debt, the Taggart paper's results imply that a formal statement of these effects can be written as:[8]

$$r_3^* = r_{A3} - r_D \times t_N \times \left(\frac{D}{V}\right) \quad \text{(B-3a)}$$

$$= r_{E3} \times \left(\frac{E}{V}\right) + r_D \times \left(\frac{D}{V}\right) \times (1 - t_C) \quad \text{(B-3b)}$$

which imply

$$r_{E3} = r_{A3} + \left[r_{A3} - r_D \times \left(\frac{1-t_D}{1-t_E}\right)\right] \times \left(\frac{D}{E}\right) \quad \text{(B-3c)}$$

Suppose, for example, that $t_C = 0.35$ percent, $t_E = 7.7$ percent and $t_D = 40$ percent. Then $[(1-t_D)/(1-t_E)] = 0.65 = (1-t_C)$. That condition corresponds to Miller's 1977 paper, in which the net personal tax advantage of equity fully offsets the net corporate tax advantage of debt. Note also that in that case, $t_N = 0$.[9] Therefore, if the personal tax advantage on equity fully offsets the corporate tax advantage on debt, Equation (B-3a) confirms that the overall after-tax cost of capital is a constant.

---

[7] As Prof. Taggart notes (his footnote 9), it is not necessary that a specific, risk-free equity security exist as long as one can be created synthetically, through a combination of long and short sales of traded assets. Such constructs are a common analytical tool in financial economics.

[8] The net all-tax effect of debt on the overall cost of capital, t_N, equals $\{[t_C + t_E - t_D - (t_C \times t_E)] / (1 - t_E)\}$, where t_D is the personal tax rate on debt, as before. This measure of net tax effect is designed for use with the cost of debt in Equation (B-3a), which seems more useful in the present context. The Taggart paper works with a similar measure, but one which is designed for use with the cost of risk-free equity in the equivalent Taggart equation.

[9] In the above example, $t_N = \{[0.35 + 0.077 - 0.4 - (0.35 \times 0.077)] / (1.0 - 0.077)\} = 0.0/0.923 = 0$.

However, it is unlikely that the personal tax advantage of equity fully offsets the corporate tax advantage of debt. If taxes were all that mattered (i.e., if there were no other costs to debt), the overall after-corporate-tax cost of capital would still fall as debt was added, just not as fast.

Finally, note that the overall after-tax cost of capital, Equation (B-3b), still uses the corporate tax rate even when personal taxes matter. Equations (B-2b) and (B-3b) both correspond to the usual formula for the ATWACC. Personal taxes affect the way the cost of equity changes with capital structure -- Equation (B-3c) -- but not the formula for the overall after-tax cost of capital given that cost of equity.

B. NON-TAX EFFECTS

Q9. Please describe the non-tax effects of Debt.

A9. If debt is truly valuable, firms should use as much as possible, and competition should drive firms in a particular industry to the same, optimal capital structure for the industry. If debt is harmful on balance, firms should avoid it. Neither picture corresponds to what we actually see. A large economic literature has evolved to try to explain why.

Part of the answer clearly is the costs of excessive debt. Here the results cannot be reduced to equations, but they are no less real for that fact. As companies add too much debt, the costs come to outweigh the benefits. Too much debt reduces or eliminates financial flexibility, which cuts the firm's ability to take advantage of unexpected opportunities or weather unexpected difficulty. Use of debt rather than internal financing may be taken as a negative signal by the market.

Even if the company is generally healthy, more debt increases the risk that the company cannot use all of the interest tax shields in a bad year. As debt continues to grow, this problem grows and others may crop up. Management begins to worry about meeting debt payments instead of making good operating decisions. Suppliers are less willing to extend trade credit, and a liquidity shortage can translate into lower operating profits.

Ultimately, the firm might have to go through the costs of bankruptcy and reorganization. Collectively, such factors are known as the costs of "financial distress."[10]

The net tax advantage to debt, if positive, is affected by costs such as a growing risk that the firm might have to bear the costs of financial distress. First, the expected present value of these costs offsets the value added by the interest tax shield. Second, since the likelihood of financial distress is greater in bad times when other investments also do poorly, the possibility of financial distress will increase the risks investors bear. These effects increase the variability of the value of the firm. Thus, firms that use too much debt can end up with a higher overall cost of capital than those that use none.

Other parts of the answer include the signals companies send to investors by the decision to issue new securities, and by the type of securities they issue. Other threads of the literature explore cases where management acts against shareholder interests, or where management attempts to "time" the market by issuing specific securities under different conditions. For present purposes, the important point is that no theory, whether based on taxes or on some completely different issue, has emerged as "the" explanation for capital structure decisions by firms. Nonetheless, despite the lack of a single "best" theory, there is a great deal of relevant empirical research.

Q10. What does that research show?

A10. The research does not support the view that debt makes a material difference in the value of the firm, at least not once a modest amount of debt is in place. If debt were truly valuable, competitive firms should use as much debt as possible short of producing financial distress, and competitive firms that use less debt ought to be less profitable. The research shows exactly the opposite.

---

[10] See, for example, Section 18.3 of Brealey, Myers and Allen, 2006, *Principles of Corporate Finance*, 8th Edition, McGraw-Hill/Irwin, 2006.

For example, Kester[11] found that firms in the same industry in both the U.S. and Japan do not band around a single, "optimal" capital structure, and the most profitable firms are the ones that use the *least* debt. This finding comes despite the fact that both countries at the time (unlike the U.S. currently) had fully "classical" tax systems, in which dividends are taxed fully at both the corporate and personal level. Wald[12] confirms that high profitability implies low debt ratios in France, Germany, Japan, the U.K., and the U.S. Booth *et al.* find the same result for a sample of developing nations.[13] Fama and French[14] analyze over 2000 firms for 28 years (1965-1992, inclusive) and conclude, "Our tests thus produce no indication that debt has net tax benefits."[15] A paper by Graham[16] carefully analyzes the factors that might have led a firm not to take advantage of debt. It confirms that a large proportion of firms that ought to benefit substantially from use of additional debt, including large, profitable, liquid firms, appear not to use it "enough."

This research leaves us with only three options: either (1) apparently good, profit-generating managers are making major mistakes or deliberately acting against shareholder interests, (2) the benefits of the tax deduction on debt are less than they appear, or (3) the non-tax costs to use of debt offset the potential tax benefits. Only the first of these possibilities is consistent with the view that the tax deductibility of debt conveys a material cost advantage. Moreover, if the first explanation were interpreted to mean that otherwise good managers are acting against shareholder interests, either

deliberately or by mistake, it would require the additional assumption that their competitors (and potential acquirers) let them get away with it.

Q11. Are there any explanations in the financial literature for this puzzle other than stupid or self-serving managers at the most profitable firms?

A11. Yes. For example, Stewart C. Myers, a leading expert on capital structure, made it the topic of his Presidential Address to the American Finance Association.[17] The poor performance of tax-based explanations for capital structure led him to propose an entirely different mechanism, the "pecking order" hypothesis. This hypothesis holds that the net tax benefits of debt (i.e., corporate tax advantage over personal tax disadvantage) are at most of a second order of importance relative to other factors that drive actual debt decisions.[18] Similarly, Baker and Wurgler (2002)[19] observe a strong and persistent impact that fluctuations in market value have on capital structure. They argue that this impact is not consistent with other theories. The authors suggest a new capital structure theory based on market timing -- capital structure is the cumulative outcome of attempts to time the equity market.[20] In this theory, there is no optimal capital structure, so market timing financing decisions just accumulate over time into the capital structure outcome. (Of course, this theory only makes sense if investors do not recognize what managers are doing.)

---

[17] Stewart C. Myers (1984), "The Capital Structure Puzzle," *The Journal of Finance*, 39: 575-592. See also S. C. Myers and N. S. Majluf (1984), "Corporate Financing Decisions When Firms Have Information Investors Do Not Have," *Journal of Financial Economics* 13:187-222.

[18] See also Stewart C. Myers (1989), "Still Searching for Optimal Capital Structure," *Are the Distinctions Between Debt and Equity Disappearing?,* R.W. Kopke and E. S. Rosengren, eds., Federal Reserve Bank of Boston.

[19] Malcolm Baker and Jeffrey Wurgler (2002), "Market Timing and Capital Structure," *The Journal of Finance* 57:1-32.

[20] *Ibid.*, p. 29.

Q12. Do inter-firm differences within an industry explain the wide variations in capital structure across the firms in an industry?

A12. No. This view is contradicted by the empirical research. As mentioned before, it has long been found that the most profitable firms in an industry, i.e., those in the best position to take advantage of debt, use the least.[21] Graham (2000) carefully examines differences in firm characteristics as possible explanations for why firms use "too little" debt and concludes that such differences are *not* the explanation: firms that ought to benefit substantially from more debt by all measurable criteria, if the net tax advantage of debt is truly valuable, voluntarily do not use it.[22]

Nor does the research support the view that firms are constantly trying to adjust their capital structures to optimal levels. Additional research on the pecking order hypothesis demonstrates that firms do not tend towards a target capital structure, or at least do not do so with any regularity, and that past studies that seemed to show the contrary actually lacked the power to distinguish whether the hypothesis was true or not.[23] In the words of the Shyam-Sunder - Myers paper p. 242, "If our sample companies did have well-defined optimal debt ratios, it seems that their managers were not much interested in getting there."

---

[21] For example, Kester, *op. cit.* and Wald, *op. cit.*

[22] While not contradicting Graham's finding that differences in firm characteristics do not explain capital structure differences, Nengjiu Ju, Robert Parrino, Allen M. Poteshman, and Michael S. Weisbach, "Horses and Rabbits? Trade-Off Theory and Optimal Capital Structure," *Journal of Financial and Quantitative Analysis*, June 2005, pp. 1-24, looks at the issue in a different manner. Their paper uses a dynamic rather than static model to analyze the tradeoff between the tax benefits of debt and the risk of financial distress. It finds that bankruptcy costs by themselves are enough to explain observed capital structures, once dynamic effects are considered. This means debt is not as valuable as suggested by the traditional static analysis (of the sort used by Graham).

[23] Lakshmi Shyam-Sunder and Stewart C. Myers (1999), "Testing static tradeoff against pecking order models of capital structure," *Journal of Financial Economics* 51:219-244.

II. EXPANDED EXAMPLE

Q13. What topics do you cover in this section?

A13. The discussion in my testimony did not detail the impact of different starting points for the level of debt nor did it address income earned on the investment, interest expense, or taxes. This section covers these topics. First, it discusses how the level of debt affects the cost of equity. Second, it addresses the influence of income and interest on the investment. Third, it explains the impact of taxes on capital structure decisions. The final topic covered in this section is the combined consequence of tax and non-tax effects of debt.

A. DETAILS OF DIFFERENT LEVELS OF DEBT

Q14. Why does more debt mean more risk for equity holders?

A14. Debt magnifies the variability of the equity return. As a simple example, think of an investor who takes money out of her savings and invests $100,000 in real estate. The future value of the real estate is uncertain. If the real estate market booms, she wins. If the real estate market goes down, she loses. Figure B-1 below illustrates this.

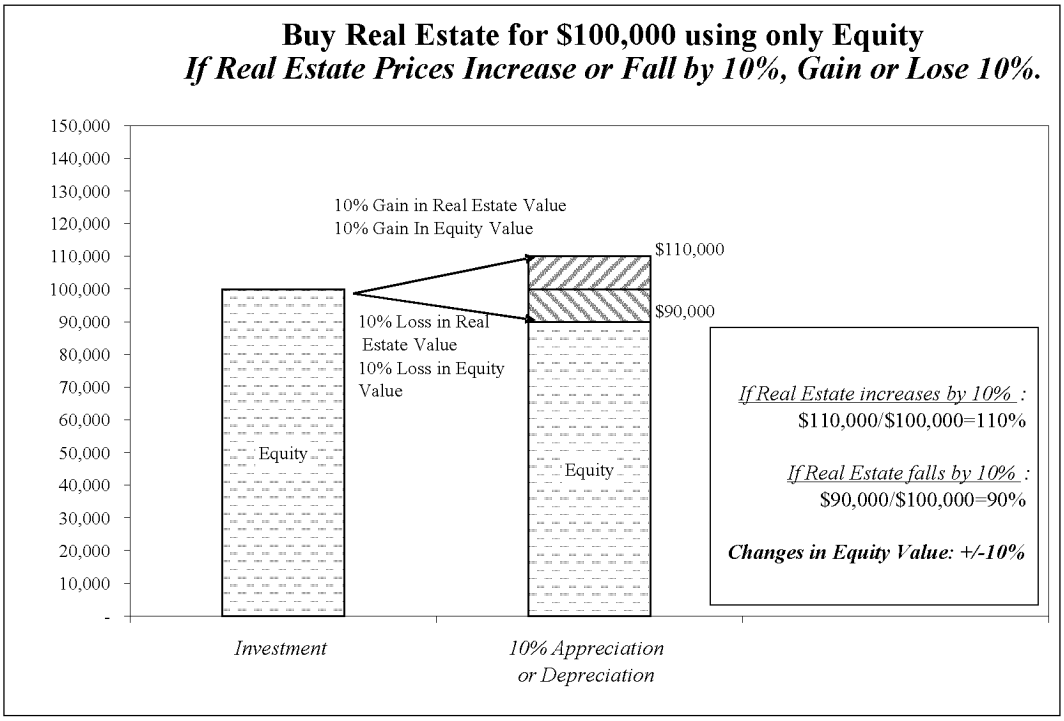

Figure B-1

In the scenario above, the investor financed her real estate purchase through 100 percent equity. Suppose instead that the investor had financed 50 percent of her real estate investment with a mortgage of $50,000. The mortgage lender does not expect to share in any benefits from increases in real estate values. Neither does the mortgage lender expect to share in any losses from falling real estate values, i.e., the investor carries the entire risk of fluctuating real estate prices. Figure B-2 illustrates this effect.

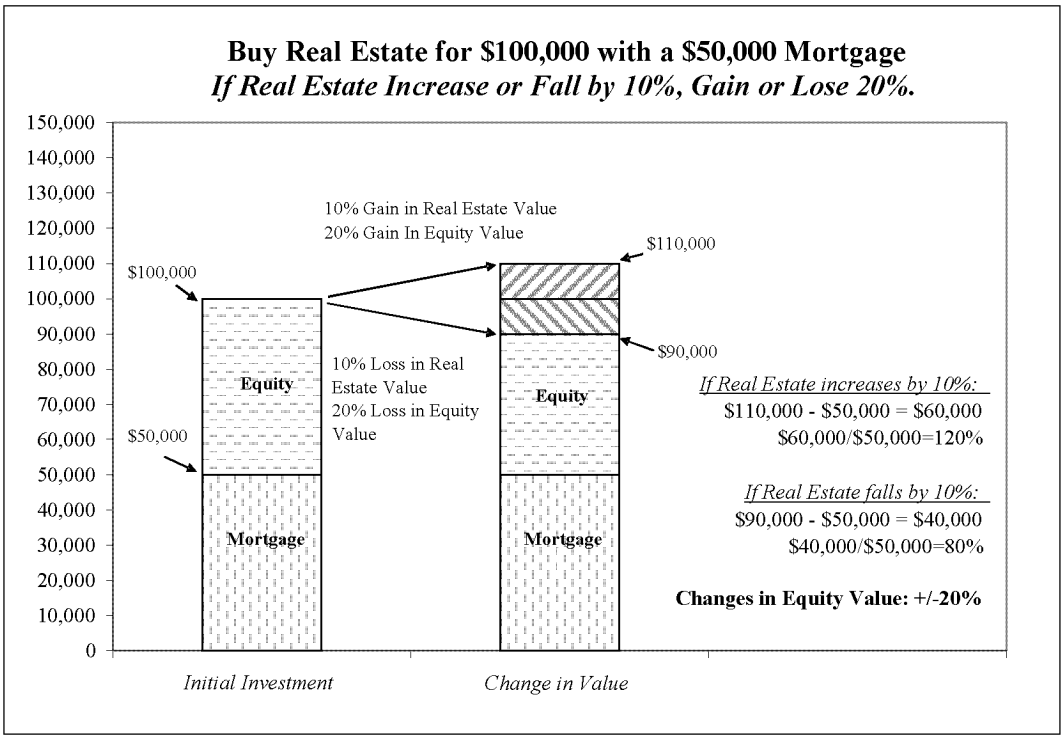

Figure B-2

In Figure B-2 where the investor financed her purchase through 50 percent equity and 50 percent debt, the variability in the investor's equity return is two times greater than that of Figure B-1. The entire fluctuation of 10 percent from rising or falling real estate prices falls on the investor's $50,000 equity investment. The lesson from the example is obvious, debt adds risk to equity.

Q15. What happens if the investor finances the real estate purchase with different proportions of debt?

A15. The equity return becomes more variable when the mortgage percentage is a greater proportion of the initial price. Table B-1 below calculates the return on equity when real estate prices increase by 10 percent when mortgages are 0 percent, 30 percent, 50 percent, and 70 percent of the initial price.

Table B-1: The Impact of Leverage on the Return on Equity

	100% Equity	70% Equity	50% Equity	30% Equity
Debt	$0	$30,000	$50,000	$70,000
Original Equity Investment	$100,000	$70,000	$50,000	$30,000
Increase in Market Value of Equity	$10,000	$10,000	$10,000	$10,000
Return on Equity Investment	10%	14.3%	20%	33.3%

Note that going from 70 percent equity down to 50 percent equity increases the return on the equity investment by 5.7 percent while going from 50 percent equity to 30 percent equity increases the return on equity by 13.3 percent. This illustrates a general point; the rate of return on equity increases more quickly at higher levels of debt than at lower levels. Investors demand a higher equity rate of return to bear more risk and debt magnifies equity's risk at an ever increasing rate. Therefore, the required equity rate of return goes up at an ever increasing rate as debt is added. This is not only basic finance theory, it is the everyday experience of anyone who buys a home. The bigger the mortgage, the more percentage risk the equity faces from changes in housing prices.

Q16. Please provide an example that illustrates why market values are relevant.

A16. Suppose in the above example that the investor has invested in real estate 10 years ago. Further assume that depreciation has reduced the book value of the real estate from $100,000 to $75,000 and assume the investor has paid off 40 percent of his $50,000 mortgage. Thus, the investor has a remaining mortgage of $30,000 (= 60% × $50,000). The book value of the investor's equity investment is therefore $45,000 (= $75,000 - $30,000).

What happens now if real estate prices rise or fall 20 percent? To answer that question, we need to know how real estate prices have developed over the past 10 years. If the

market value of the real estate now is $200,000 then a 20 percent decrease in the price of real estate ($40,000) is almost equal to the investor's book value equity. However, his market value equity (or net worth) is equal to the value of the real estate minus what he owes on the mortgage. If we assume that the market value of the mortgage equals the unpaid balance ($30,000), then the investor's net worth is calculated as follows:

Net Worth	=	Market Value of Real Estate	-	Remaining Mortgage
	=	$200,000	-	$30,000
	=	$170,000		

Therefore, the rate of return on equity due to a 20 percent decline in real estate prices is calculated in Table B-2.

Table B-2: Calculating the Rate of Return on Equity

Decline in Real Estate Value	$40,000
Market-Value Equity	$170,000
Rate of Return on Equity	- $40,000/$170,000 = -23.5%

B. THE IMPACT OF INCOME AND INTEREST

Q17. How does earning income from the investment and paying interest on debt affect the results?

A17. In the following explanation, I ignore income taxes which I deal with in Section C. Assume the investor is receiving income, e.g., rent, from the real estate. Specifically, assume the investor receives $500 per month in income after all non-interest expenses ($6,000 per year). Also, assume that the expected appreciation is 5 percent per year, so

the expected market value is $105,000 after one year. Then the expected rate of return from the real estate with all equity financing is:

$$\text{Expected Return on Equity @ 0\% debt} = \frac{\text{Expected Net Income + Expected Appreciation}}{\text{Initial Investment}}$$

$$= \frac{\$6{,}000 + (\$105{,}000 - \$100{,}000)}{\$100{,}000}$$

$$= 11\%$$

Now suppose that the mortgage interest rate were 5 percent. Then at a mortgage equal to 50 percent, or $50,000, interest expense would be ($50,000 x 0.05), or $2,500. The expected equity rate of return would be:

$$\text{Expected Return on Equity @ 50\% debt} = \frac{\text{Expected (Net Income + Appreciation) – Int. Expense}}{\text{Initial } \textit{Equity} \text{ Investment}}$$

$$= \frac{\$6{,}000 + \$5{,}000 - \$2{,}500}{\$50{,}000}$$

$$= 17\%$$

Notice that the expected return on equity is higher as is the risk carried by equity.

Q18. Can you provide a more general illustration?

A18. Yes. Figure B-3 uses these assumptions at different mortgage levels to plot both (i) the expected rate of return on the equity in the dwelling, and (ii) the realized rate of return on

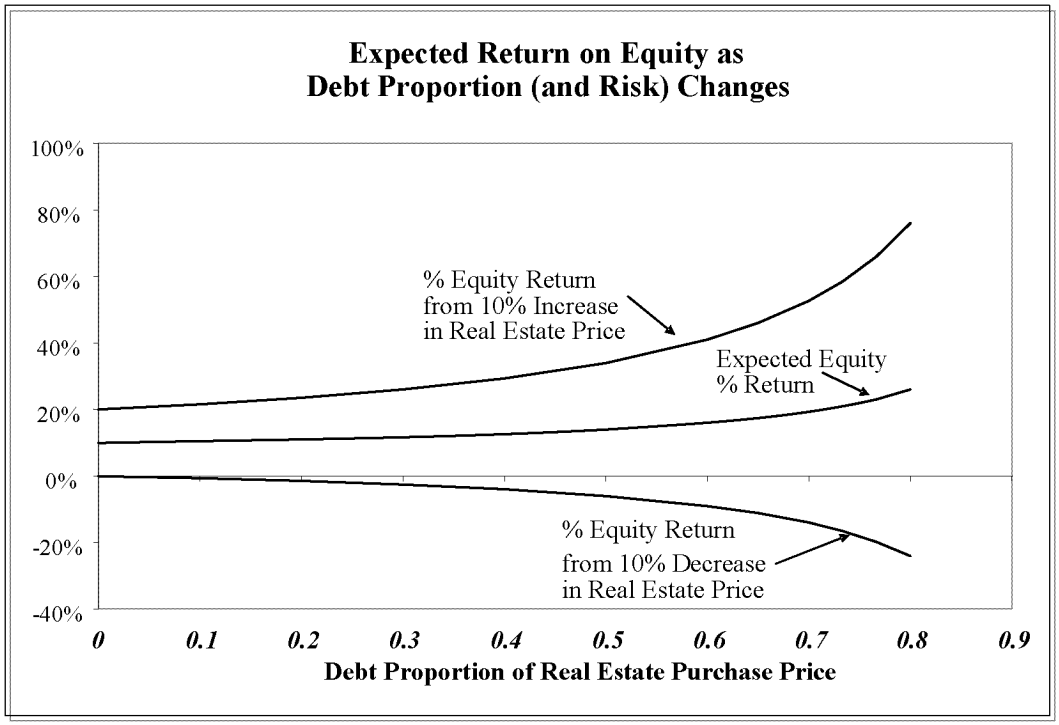

Figure B-3

that equity in a year if the dwelling value increases by 10 percent more than the expected 5 percent rate (i.e., if the value increases by 15 percent) or by 10 percent less than expected (i.e., if it decreases by 5 percent).[24]

The expected rate of return on equity increases at an increasing rate as the investor finances more and more of the real estate through loans (e.g., with a mortgage). Since equity bears all the risk of increases or decreases in real estate values (absent financial distress or bankruptcy), the amount of risk the buyer bears grows at an ever increasing rate as the mortgage percentage also increases.

Q19. What are the implications of this example?

A19. Any time an individual or a company uses debt to finance part an investment, the same risk magnifies. For example, if an investor buys stocks "on margin" -- by borrowing part

[24] For simplicity, the figure assumes the debt's interest rate is independent of the debt proportion. This might not always be true, and in general would not be true for a corporation that issued debt. However, the general shape of the graphs remains the same.

of the money used to buy the stock -- the expected rate of return will be higher as will the risks the investor carries. As an everyday example, imagine investing your retirement savings in a stock portfolio bought with as much margin as possible. If you were lucky, you could end up living very well in retirement. But you would be taking a lot of risk on the opposite outcome, since your portfolio could decline by more than 100 percent of your initial investment.

The same risk-magnifying effects happen when companies borrow to finance part of their investments.

C. THE EFFECT OF TAXES

Q20. What is the impact of taxes?

A20. Analyzing the net effect of taxes in capital structure decisions by corporations is an important part of the financial research. (Other parts of that research address such issues as the risk of financial distress or bankruptcy, and the signals corporations send investors by the choice of how to finance new investments.) The bottom line is that taxes complicate the picture without changing the basic conclusion.

Q21. Please describe the potential impact of taxes.

A21. Interest expense is tax-deductible for corporations. That increases the pool of cash the corporation gets to keep out of its operating earnings (i.e., its earnings before interest expense). With no debt, 100 percent of operating income is subject to taxes. With debt, only the equity part of the operating income is subject to taxes.

All else equal, the extra money kept from operating income increases the value of the corporation. The standard way to recognize that increase in value is to use an after-tax weighted-average cost of capital as a discount rate when valuing a company's operating cash flows.

Q22. Do personal taxes affect the value of debt, too?

A22. Yes, but in the other direction. One offset to debt's tax benefits at the corporate level is its higher tax burden at the personal level. Investors care about the money they get to keep after all taxes are paid, and while the corporation saves taxes by opting for debt over equity, individuals pay more taxes on interest than on capital gains from equity (and for now, on dividends as well).

Q23. Are there factors other than taxes matter?

A23. Absolutely, "all else" does not remain equal as more debt is added. The more debt, the more the non-tax effects of debt offset the tax benefits. Other costs include such effects as a loss of flexibility, the possibility of sending negative signals to investors, and a host of costs and risks associated with the danger of financial distress.

Q24. Does the tradeoff between the tax and non-tax effects of debt mean that firms have well-defined, optimal capital structures?

A24. No, this sort of "tradeoff" model does not explain actual corporate behavior. A substantial body of economic research confirms that real-world corporations act as if, after a moderate amount of debt is in place, the tax benefits of debt are not worth debt's other costs. In country after country and in industry after industry, the most profitable corporations in an industry tend to use the least debt. The research on this point is quite thorough, and the finding that the most profitable companies tend to use the least debt in a given industry is robust. Yet these are the companies with the most operating income to shield from taxes, who would benefit most if interest tax shields were truly valuable net of debt's other costs. They also presumptively are the best-managed on average (else why are they the most profitable?). This means it is unrealistic to suppose that more debt is always better, or that greater tax savings due to higher interest expense always add value to the firm on balance.

Q25. If the tradeoff model doesn't explain capital structure decisions by firms, is there a model that does?

A25. No single model has (yet) emerged as 'the" explanation of capital structure. However, several alternative models attempt to model the tradeoff (e.g., the "pecking order" hypothesis and "agency cost" explanations).

Q26. What does the absence of an agreed theory of capital structure in the financial literature imply about the overall effect of debt on the value of the firm?

A26. The findings of the financial literature mean that within an industry, there is no well-defined optimal capital structure. The use of some debt does convey some value advantage in most industries, but that advantage is offset by other costs as firms add more debt.[25] The range of capital structures over which the value of the firm in any industry is maximized is wide and should be treated as flat. The location and level of that range, however, does vary from industry to industry, just as the overall cost of capital varies from industry to industry.

Figure B-4 illustrates the picture that emerges from the research. This figure shows the present value of an investment in each of four different industries. For simplicity, the investment is expected to yield $1.00 per year forever. For firms in relatively high-risk industries (Industry 1 in the graph, the lowest line), the $1.00 perpetuity is not worth much and any use of debt decreases firm value. For firms in relatively low-risk industries (Industry 4 in the graph), the perpetuity is worth more and substantial amounts of debt make sense. Industries 2 and 3 are intermediate cases.

The maximum net rate at which taxes can increase value in this figure equals 20 percent of interest expense, representing a balance between the corporate tax advantage to debt

[25] Note that if debt did increase the value of the firm materially, competition would tend to take that value away, since issuing debt is an easy-to-copy competitive strategy. Prices would fall as firms copied the strategy, lowering operating earnings and passing the net tax advantages to debt through to customers (just as happens under rate regulation). Therefore, if also there were a narrow range of optimal capital structures within an industry, competition would drive all firms in the industry to capital structures within that range. This does not happen in practice, which contradicts one or both of the assumptions, i.e., (1) that debt adds material value on balance, and/or (2) that there is a narrow range of optimal capital structures.

and the personal tax disadvantage. The figure plots the maximum possible impact of taxes on value as a separate line, starting at the all-equity value of the lowest-risk industry (Industry 4).

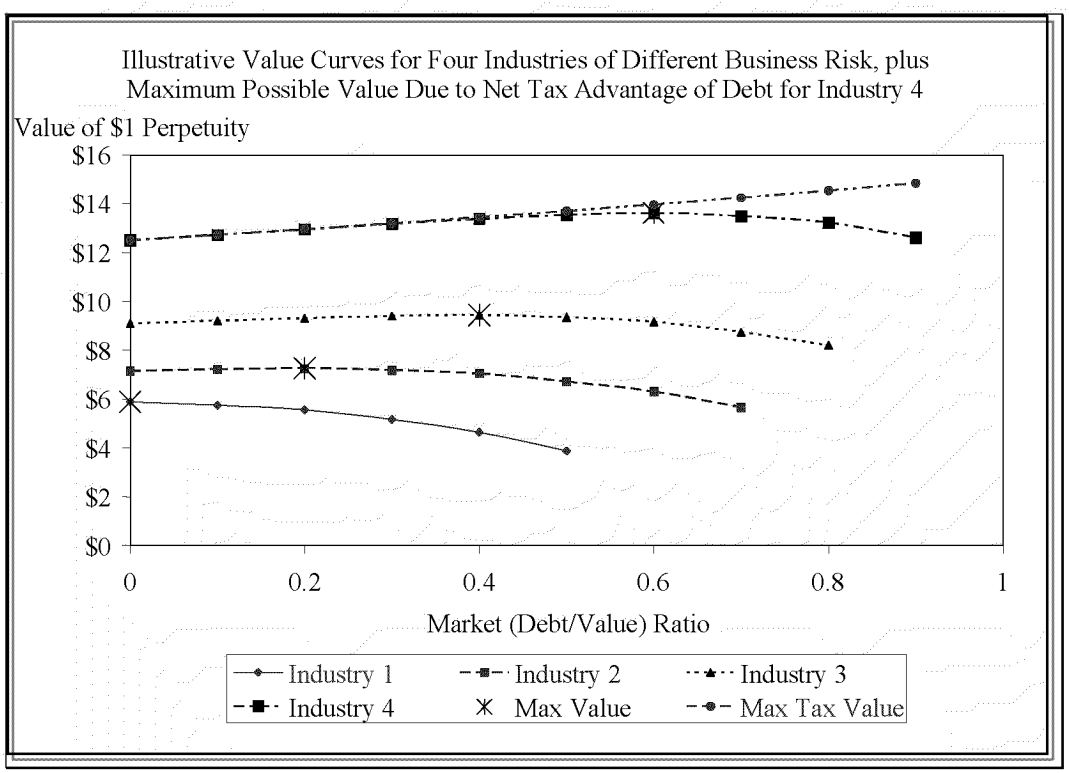

Figure B-4

Figure B-4 identifies a particular point as the maximum value on each of the four curves. However, the research shows that reliable identification of this maximum point, except in the extreme case where no debt should be used, is impossible. In accord with the research, the graph is prepared so that in none of the industries does a change in capital structure make much difference near the top of the curve. Even Industry 4, which increases in value at the maximum rate as quite a lot of debt is added, eventually must reach a broad range where changes in the debt ratio make little difference to firm value, given the research. For Industry 4, debt makes less than a 2 percent difference in the total value of the firm for debt-to-value ratios between 40 and 70 percent. (While these

particular values are illustrative, numbers of this order of magnitude are the only ones consistent with the research.)

Q27. What does this imply for the overall cost of capital?

A27. Figure B-5 plots the after-tax weighted-average costs of capital ("ATWACCs") that correspond to the value curves in Figure B-4. This picture just turns Figure B-4 upside down.[26] All the same conclusions remain, except that they are stated in terms of the overall cost of capital instead of the overall firm value. In particular, except for high-risk industries, the overall cost of capital is essentially flat across a broad middle range of capital structures for each industry, which is the only outcome consistent with the research. For Industry 4, for example, the ATWACC changes by less than 15 basis points for debt-to-value ratios between 40 and 70 percent.

[26] Note that the actual estimated ATWACC at higher debt ratios will tend to underestimate the ATWACC that corresponds to the value curves in Figure B-4, which are depicted in Figure B-5, and so will tend to overestimate the value of debt to the firm. The reason is that some of the non-tax effects of excessive debt, such as a loss of financial flexibility, may be hard to detect and not show up in cost of capital measurement.

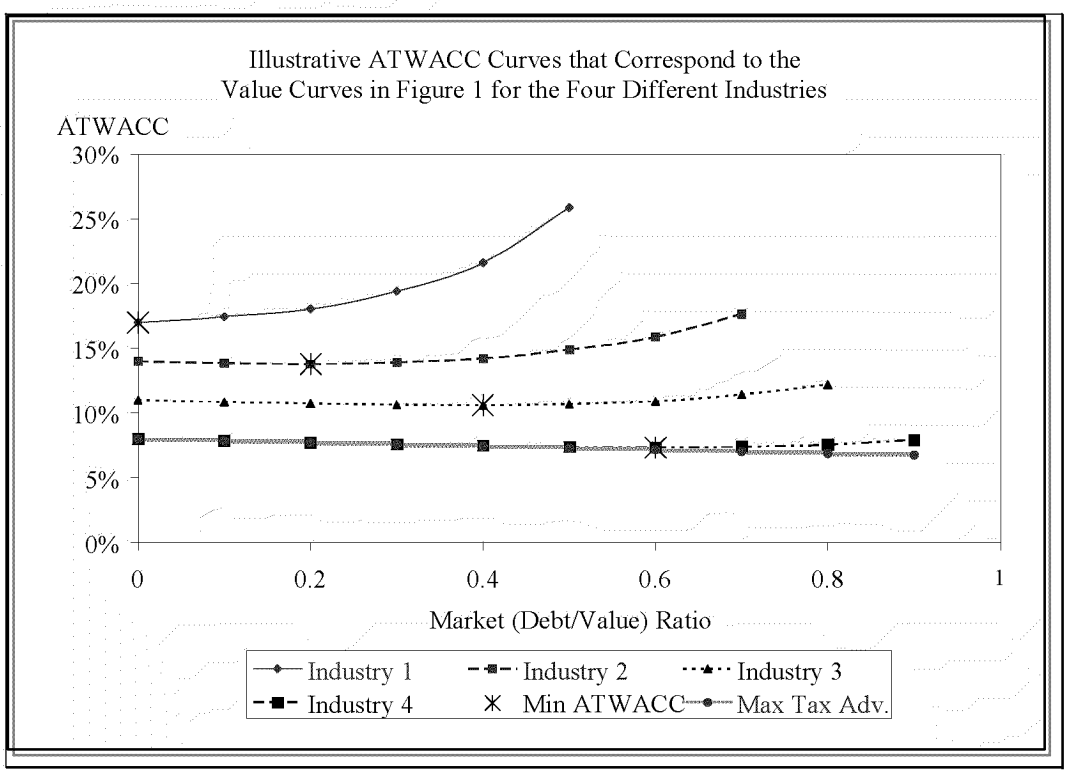

Figure B-5

Q28. How does this discussion relate to estimation of the right cost of equity for ratemaking purposes?

A28. When an analyst estimates the cost of equity for a sample of companies, s/he does so at the sample's actual market-value capital structure. That is, the sample evidence corresponds to ATWACCs that are already out somewhere in the broad middle range in which changes in the debt ratio have little or no impact on the overall value of the firm or the ATWACC.

An analyst therefore should assume the ATWACCs for the sample companies are literally flat. This assumption always provides the exact tradeoff between the cost of equity and capital structure at the literal minimum of the company's ATWACC curve. The research shows that this minimum is actually a broad, flat region, as depicted above. If the company happens to be somewhat to one side or the other of the literal minimum within this region, the recommended procedure may lead to a small understatement or overstatement of the amount that the cost of equity will change as capital structure

changes. The degree of this under- or overstatement, however, is very small compared to the inherent uncertainty in estimating the cost of equity in the first place. Otherwise, the financial research would have found very different results about the existence of a narrowly defined optimal capital structure.

D. COMBINED EFFECTS

Q29. Please summarize the implications for the combined impact of the tax and non-tax effects of debt.

A29. The most profitable firms do not behave as if the precise amount of debt they use makes any material difference to value, and competition does not force them into an alternative decision, as it would if debt were genuinely valuable. The explanation that fits the facts and the research is that within an industry, there is no well-defined optimal capital structure. Use of some debt does convey an advantage in most industries, but that advantage is offset by other costs as firms add more debt. The range of capital structures over which the value of the firm in any industry is maximized is wide and should be treated as flat. The location and level of that range, however, does vary from industry to industry, just as the overall cost of capital varies from industry to industry. To conclude that more debt does add more value, once the firm is somewhere in the normal range for the industry, is to conclude that corporate management in general is either blind to an easy source of value or otherwise incompetent (and that their competitors let them get away with it).

The finding that there is no narrowly defined optimal capital structure implies that analysts should estimate the ATWACCs for a sample of companies in a given industry and treat the average ATWACC value as independent of capital structure (at least within a broad middle range of capital structures). The right cost of equity for a rate-regulated company in the same industry is the number that yields the same ATWACC at the capital structure used to set the revenue requirement, since that is the cost of equity that

(estimation problems aside) the sample companies would have had if their market-value capital structures had been equal to the regulatory capital structure.

APPENDIX A: RESUME

APPENDIX B: SELECTING THE GAS LDC SAMPLE AND USE OF MARKET VALUES

I. INTRODUCTION AND SUMMARY

Q1. Please state your name and address for the record.

A1. My name is Michael J. Vilbert. My business address is The Brattle Group, 44 Brattle Street, Cambridge, MA 02138, USA.

Q2. Please describe your job and your educational experience.

A2. I am a Principal of The Brattle Group, ("Brattle"), an economic, environmental and management consulting firm with offices in Cambridge, Washington, London, San Francisco and Brussels. My work concentrates on financial and regulatory economics. I hold a B.S. from the U.S. Air Force Academy and a Ph.D. in finance from the Wharton School of Business at the University of Pennsylvania.

Q3. What is the purpose of your testimony in this proceeding?

A3. I have been asked by NorthWestern Energy Corp. ("NorthWestern" or the "Company") to estimate the cost of equity that the Public Utilities Commission of the State of South Dakota (the "Commission") should allow NorthWestern an opportunity to earn on the equity financed portion of its South Dakota gas utility assets, which provide retail gas distribution service in South Dakota.

To accomplish this task, I estimate the overall cost of capital for a sample of regulated natural gas local distribution companies ("LDCs") using the discounted cash flow ("DCF") and risk positioning models. I then evaluate the relative business and financial risk of NorthWestern's South Dakota natural gas operations ("NorthWestern's SD operations") to the gas LDC sample. These comparisons are important in determining my recommended cost of equity for a regulatory capital structure with 51.5 percent equity, which is the percent equity in the Company's proposed capital structure in this proceeding.

Q4. Please summarize the parts of your background and experience that are particularly relevant to your testimony on these matters.

A4. Brattle's specialties include financial economics, regulatory economics, and the gas and electric industries. I have worked in the areas of cost of capital, investment risk and related matters for many industries, regulated and unregulated alike, in many forums. I have testified or filed cost of capital testimony before the Federal Energy Regulatory Commission, the Arizona Corporation Commission, the Pennsylvania Public Utility Commission, the Public Service Commission of West Virginia, the Tennessee Regulatory Authority, the Canadian National Energy Board, Alberta Energy and Utilities Board, the Ontario Energy Board, and the Labrador & Newfoundland Board of Commissioners of Public Utilities. I have not previously testified before this Commission. Appendix A contains more information on my professional qualifications.

Q5. What is your conclusion on the market-determined cost of equity for NorthWestern's SD operations based upon the results from the sample of regulated companies you selected?

A5. The best point estimate of the cost of equity for NorthWestern's SD gas distribution operations is 11¼ percent for a capital structure with 51.5 percent equity. However, it is more correct to say that the sample results indicate a range of 10¾ to 11¾ percent for the estimated cost of equity. This point estimate is about ½ percent lower than the risk-positioning results for the sub-sample and almost 1 percent higher than the multistage DCF estimate for the sub-sample.

Note, I specify a plus or minus ½ percent range for the return on equity and specify the point estimate to the nearest ¼ percent because I do not believe that it is possible to estimate the cost of equity more precisely than that.

Q6. How is your testimony organized?

A6. The *Sections II and III* of the testimony cover the theory underlying the cost of equity estimation models. Those familiar with cost of capital theory can skip directly to *Section*

IV, which discusses the implementation of the models in this proceeding. *Section V* provides the conclusions.

Specifically, *Section II* formally defines the cost of capital and touches on the principles relating to the cost of capital and capital structure for a business. *Section III* presents the methods used to estimate the cost of capital for the benchmark samples and their associated numerical analyses, and explains the basis of my conclusions for the benchmark sample's returns on equity and overall cost of capital. *Section IV* presents the results of these methods applied to the benchmark sample group, and presents the cost of equity implied by the results. *Appendix B* discusses sample selection and the determination of the market-value capital structures as well as the costs of debt and preferred stock. My conclusions on the cost of equity for the equity financed portion of NorthWestern's South Dakota gas utility assets are presented in *Section V*.

Q7. Please summarize how you approached this task.

A7. I selected a sample of nine regulated natural gas LDCs with business risk comparable to that of NorthWestern's SD gas LDC operations. My analyses consider cost of capital evidence from the risk positioning and discounted cash flow models, but I rely primarily on the results from the risk positioning model because I do not believe that the DCF method is completely reliable at this time for this industry.

Specifically, I estimate the cost of equity for each sample company using both cost-of-equity estimation methods. For each estimate, I combine this value with the sample company's market costs of debt and preferred stock to estimate each firm's overall cost of capital, i.e. its after-tax weighted-average cost of capital ("ATWACC"), using each company's market value capital structure as the weights. For each method of estimating the return on equity, I then report a sample average ATWACC and the estimated cost of equity at a capital structure with same percentage of equity as filed by NorthWestern for its SD operations. I thus present the cost of equity that is consistent with each sample's

market information on the cost of capital and the regulatory capital structure of NorthWestern's SD operations. (By "regulatory capital structure," I mean the capital structure that NorthWestern utilizes in its applications.[1])

This method automatically avoids problems that can arise when an analyst focuses separately on the individual components of the overall cost of capital (i.e., the cost of equity and the appropriate capital structure). The danger with that approach is that the estimated cost of equity from the sample may correspond to a very different level of financial risk than would exist at the regulated company's capital structure. The result could be an inconsistency between the allowed return on equity and the financial risk inherent in the regulatory capital structure.

Q8. Why do you believe that the DCF model is less reliable for this industry at this time than the risk positioning model?

A8. Results for the DCF model depend critically on the estimate of the dividend growth rate. A one percent error in the estimate of the growth rate results in a greater than one percent error in the cost of equity estimates. In the recent past, the gas LDC industry could have been characterized as being relatively stable, but that is much less true today. There have been a number of mergers and acquisitions that has resulted in a consolidation within the industry. There are now fewer "pure play" gas LDC companies available to include in a sample. Gas prices have increased dramatically and have been much more volatile lately. Although most of the companies in the gas LDC sample have fuel cost adjustment clauses, the increased volatility of gas prices has increased the uncertainty of the industry's earnings going forward. This uncertainty in earnings is also reflected in the accounting restatements by companies in the industry due to efforts to report accurately the value of inventories. Currently, average forecast growth rates for the sample are lower than they were just a few months ago, but *Value Line's* forecast betas have changed

[1] In the analyses I use the capital structure that is based upon the long-term sources of capital, i.e., long-term debt, preferred equity and common equity. I do not use short-term debt because long-term assets are not generally financed with short-term debt.

very little. Because of these concerns, I report results for a sub-sample which consists of sample companies which have no significant data issues. Estimates from this group are likely to be the most reliable.

Q9. What are the results for the DCF model?

A9. As reported below, the DCF model results display a greater spread and are more variable and therefore less reliable than those based upon the risk positioning model. For example, the simple DCF model results range from a low of 6.5 percent to a high of 10.1 percent before any consideration of differences in financial risk. Results for the more reliable multistage model are less variable, and range from 7.4 to 9.8 percent. (See Table No. MJV-6, Panel A for the simple DCF and Panel B for the multistage DCF) After adjusting for financial risk, the sample average for the multistage DCF model is 9.7 percent for the full sample and 10.3 percent for the more reliable subsample. The corresponding DCF results for the less reliable simple DCF model are 9.1 percent for the full sample and 9.4 for the sub-sample. (Table No. MJV-8, Panels A and B)

Although I do not believe that the DCF results are completely reliable for the reasons stated above, I provide results using the DCF method because it is a method that has been used extensively in the past. In addition, the results from the DCF model serve as a check on the results from the equity risk positioning approach.

Q10. What were the results for the risk positioning model?

A10. The sample average risk positioning results adjusted for differences in financial risk range from a low of 11.1 percent to a high of 11.4 percent for the full sample and 11.5 to 11.8 percent for the more reliable sub-sample when using the long-term risk free rate. (See Table No. MJV-12, Panel A for the full sample and Panel B for the sub-sample.) I also report results for the risk positioning model based upon the short-term risk-free rate, but I do not rely on those estimates in this proceeding.

Q11. You mentioned the importance of considering financial risk when evaluating the results of the models. Please explain how you adjust for financial risk.

A11. Both the DCF and the risk positioning models rely on market data to estimate the cost of equity for the sample companies. That cost of equity estimate captures both the business risk and the financial risk of the assets. Business risk is the risk that the company would have if it were financed entirely with equity. Financial risk is the additional risk carried by the equity holders when debt is used to finance some of the assets. The more debt that is used by a company, the riskier the company's equity becomes. As explained in more detail below, the procedures I use consider both the business risk and the financial risk of the sample companies in comparison to NorthWestern's SD gas operations in determining my recommended cost of equity.

II. COST OF CAPITAL THEORY

A. THE COST OF CAPITAL AND RISK

Q12. Please formally define the "Cost of Capital."

A12. The cost of capital can be defined as *the expected rate of return in capital markets on alternative investments of equivalent risk*. In other words, it is the rate of return investors require based on the risk-return alternatives available in competitive capital markets. The cost of capital is a type of opportunity cost: it represents the rate of return that investors could expect to earn elsewhere without bearing more risk. "Expected" is used in the statistical sense: the mean of the distribution of possible outcomes. The terms "expect" and "expected" in this testimony, as in the definition of the cost of capital itself, refer to the probability-weighted average over all possible outcomes.

The definition of the cost of capital recognizes a tradeoff between risk and return that is known as the "security market risk-return line," or "security market line" for short. This line is depicted in Figure 1. The higher the risk, the higher is the cost of capital. A

version of Figure 1 applies for all investments. However, for different types of securities, the location of the line may depend on corporate and personal tax rates.

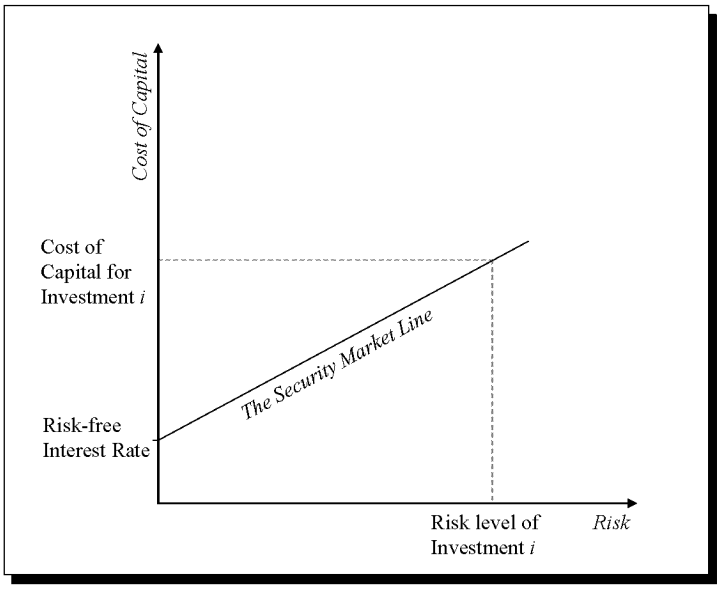

Figure 1: The Security Market Line

Q13. Why is the cost of capital relevant in rate regulation?

A13. It has become routine in U.S. rate regulation to accept the "cost of capital" as the right expected rate of return on utility investment.[2] That practice is normally viewed as consistent with the U.S. Supreme Court's opinions in *Bluefield Waterworks & Improvement Co. v. Public Service Commission*, 262 U.S. 678 (1923), and *Federal Power Commission v. Hope Natural Gas*, 320 U.S. 591 (1944).

From an economic perspective, rate levels that give investors a fair opportunity to earn the cost of capital are the lowest levels that compensate investors for the risks they bear. Over the long run, an expected return above the cost of capital makes customers overpay for service. Regulatory commissions normally try to prevent such outcomes, unless there are offsetting benefits (e.g., from incentive regulation that reduces future cost). At the

[2] A formal link between the cost of capital as defined by financial economics and the right expected rate of return for utilities is established by Stewart C. Myers, "Application of Finance Theory to Public Utility Rate Cases," *The Bell Journal of Economics and Management Science*, 3:58-97 (Spring 1972).

same time, an expected return below the cost of capital shortchanges investors. In the long run, such a return denies the company the ability to attract capital, to maintain its financial integrity, and to expect a return commensurate with that of other enterprises attended by corresponding risks and uncertainties.

More important for customers, however, are the economic issues an inadequate return raises for them. In the short run, deviations of the expected rate of return on the rate base from the cost of capital create a "zero-sum game"-- investors gain if customers are overcharged, and customers gain if investors are shortchanged. In the long run, however, inadequate returns are likely to cost customers -- and society generally -- far more than is gained in the short run. Inadequate returns lead to inadequate investment, whether for maintenance or for new plant and equipment. The costs of an undercapitalized industry can be far greater than the short-run gains from shortfalls in the cost of capital. Moreover, in capital-intensive industries (such as the electric utility or the gas distribution industries), systems that take a long time to decay cannot be fixed overnight. Thus, it is in the customers' interest not only to make sure the return investors expect does not exceed the cost of capital, but also to make sure that it does not fall short of the cost of capital, either.

Of course, the cost of capital cannot be estimated with perfect certainty, and other aspects of the way the revenue requirement is set may mean investors expect to earn more or less than the cost of capital even if the allowed rate of return equals the cost of capital exactly. However, a Commission that sets rates so investors expect to earn the cost of capital on average treats both customers and investors fairly, and acts in the long-run interests of both groups.

B. Business Risk & Financial Risk: Capital Structure and the Cost of Equity

Q14. Please explain briefly the difference between business risk and financial risk.

A14. Business risk is the risk of a company from its line of business if it used no debt financing. When a firm uses debt to finance its assets, the business risk of the assets is shared between the debt holders and the equity holders, but the equity holders bear more of the risk because debt holders have a prior claim on the company's cash flows. Equity holders are residual claimants, which simply means that equity holders get paid last. Therefore, the goal of selecting a sample is to choose companies whose business risk is comparable to the regulated company in the proceeding.

Q15. Please explain why it is necessary to report the cost of equity adjusted for capital structure.

A15. Briefly, rate regulation in North America tends to focus on the components of the overall cost of capital, and in particular, on what the "right" cost of equity and capital structure should be. Frequently, there is no consideration of whether the financial risks of the sample companies differ among themselves or differ from the regulated company. The cost of equity estimated using the standard models reflects both the business and financial risk of the sample companies. However, the overall cost of capital depends primarily on the business the firm is in, while the costs of the debt and equity components depend not only on the business risk but also on the distribution of revenues between debt and equity. The overall cost of capital is thus the more basic concept.

C. Implications for Analysis

Q16. Please explain the implications of the relationship between capital structure and the cost of equity on your testimony.

A16. The risk equity holders carry, and therefore the cost of equity, depends on the capital structure. As leverage increases, financial risk increases, and hence the required return on equity increases. An approach that estimates the cost of equity for each of the sample

firms without explicit consideration of the market value capital structure (i.e., the financial risk) underlying those costs risks material errors. The costs of equity of the sample companies at their actual market-value capital structures do not necessarily correspond to the financial risk faced by equity holders in the regulated company, and thus could lead to an unfair rate of return. I avoid this problem by calculating each sample company's ATWACC using its market value capital structure. Using the sample's average overall cost of capital as an estimate for the cost of capital of NorthWestern's SD operations, I then determine the corresponding return on equity at NorthWestern's filed regulatory capital structure. This procedure ensures that the capital structure and estimated cost of equity are consistent for the regulated company.

Q17. To assess the magnitude of financial risk for a rate regulated company, should you use the market-value or the book-value capital structure?

A17. The academic literature supports the view that the market-value capital structure is the relevant quantity for analyzing the cost of equity evidence, which is based on market information.

Q18. Is the use of market values to calculate the impact of capital structure on the risk of equity incompatible with use of a book-value rate base for a regulated company?

A18. No, no more than it is incompatible to use market-based cost of equity estimation methods (such as DCF or the risk positioning model) with a book value rate base. That is, the cost of capital is the fair rate of return on regulatory assets for both investors and customers. Most regulatory jurisdictions in North America measure the rate base using the net book value of assets, not current replacement value or historical cost trended for inflation, but the jurisdictions still apply market-derived measures of the cost of equity to that net book value rate base.

The issue here is "what level of risk is reflected in that cost of equity estimate?" The equity risk level depends on the sample company's market-value capital structure, not its book-value capital structure. *That risk level would be different if the sample company's*

market-value capital structure exactly equaled its book-value capital structure, so the estimated cost of equity would be different, too.

Q19. Please sum up the implications of this section.

A19. The market risk and, therefore, the cost of equity depend directly on the market-value capital structure of the company or asset in question. It therefore is impossible to compare validly the measured costs of equity of different companies without taking capital structure into account. Capital structure and the cost of equity are inextricably linked, and any effort to treat the two as separate and distinct questions violates basic financial principles.

Q20. How should a cost of capital analyst implement this principle?

A20. Analysts should treat the market-value weighted average of the cost of equity and the after-tax current cost of debt, or the "ATWACC" for short,[3] as constant for a particular line of business for companies not in financial distress or with unusual capital structures. Sample evidence should be analyzed to determine the sample's average ATWACC, which can be compared across different firms or industries. The economically appropriate cost of equity for a regulated firm is the quantity that, when applied to the *regulatory* capital structure, produces the same ATWACC. That value is the cost of equity that the sample would have, estimation problems aside, if the sample's market-value capital structure had been equal to the regulatory capital structure in question.

[3] This quantity typically is called the "weighted-average cost of capital" or "WACC" in finance textbooks. The textbook WACC equals the *market*-value weighted average of the cost of equity and the *after-tax*, *current* cost of debt. However, rate regulation in North America has a legacy of working with another weighted-average cost of capital, the *book*-value weighted average of the cost of equity and the *before-tax*, *embedded* cost of debt. Accordingly, in regulatory settings it's useful to refer to the textbook WACC as the "ATWACC," or "after-tax weighted-average cost of capital." I follow that practice here.

Q21. Can you provide a simple example of the calculation of the cost of equity consistent with the market-determined estimate of the sample's average overall cost of capital?

A21. Yes. Consider the following equation to calculate the ATWACC:[4]

$$ATWACC = r_D \times D \times (1 - T_C) + r_E \times E \quad (1)$$

where r_D = market cost of debt,
r_E = market cost of equity,
T_C = corporate income tax rate,
D = percentage of debt in the capital structure, and
E = percentage of equity in capital structure.

The cost of equity consistent with overall cost of capital estimate (ATWACC), the market cost of debt and equity, the marginal corporate income tax rate and the amount of debt and equity in the capital structure can be determined by solving equation (1) for r_E.

III. COST OF CAPITAL METHODOLOGY

Q22. How is this section of your testimony organized?

A22. As noted in Section II, I estimate the cost of capital using a sample of comparable risk companies. This section first outlines the steps involved in selecting a benchmark sample, in determining the market-value capital structure, and in estimating the sample companies' costs of debt. It then turns to the procedures for estimating the costs of equity and describes the two cost of equity estimation methodologies used in this testimony, the DCF method and the risk positioning approach. These are the foundations of my cost of capital calculations, which I present in the following section and which I use to derive my recommended cost of equity for NorthWestern's SD regulated gas assets at their regulatory capital structure.

[4] Note that this equation assumes that only debt and equity are in the capital structure, but it is simple to add preferred equity to the equation.

A. SAMPLE SELECTION CRITERIA

Q23. What is the goal of your sample selection procedures?

A23. The overall cost of capital for a part of a company depends on the risk of the business in which the part is engaged, not on the overall risk of the parent company on a consolidated basis. According to financial theory, the overall risk of a diversified company equals the market-value-weighted average of the risks of its components.

Estimating the cost of equity for NorthWestern's SD regulated gas distribution assets is the subject of this proceeding. The ideal comparative sample for NorthWestern's SD operations would be a number of companies that are publicly traded "pure plays" in the natural gas distribution business. "Pure play" is an investment term referring to companies with operations only in one line of business. Publicly traded firms, firms whose shares are freely traded on stock exchanges, are ideal because the best way to infer the cost of capital is to examine evidence from capital markets on companies in the given line of business.

In addition to providing a sample of comparable business risk, a good sample should provide reliable cost of capital estimates. For this reason, I apply a set of criteria that are intended to screen out companies that have characteristics which may bias the cost of equity estimates. The details are in Appendix B.

B. CAPITAL STRUCTURE & THE COST OF DEBT

1. Market-Value Capital Structure

Q24. What capital structure information do you require?

A24. For reasons discussed above, explicit evaluation of the market-value capital structures of the sample companies is vital for a correct interpretation of the market evidence on the return on equity. This requires estimates of the market values of common equity, preferred equity and debt, and the current market costs of preferred equity and debt.

Q25. Please describe how you calculate the market values of common equity, preferred equity and debt.

A25. I estimate the market value capital structure for each sample company by estimating the market values of common equity, preferred equity and debt from the most recent publicly available data. The details are in Appendix B.

Briefly, the market value of common equity is the price per share times the number of shares outstanding. For the risk positioning approach, I use the last five trading days of each year to calculate the market value of equity for the year. I then calculate the average capital structure over the corresponding five-year period used to estimate the "beta" risk measures for the sample companies.[5] This procedure matches the estimated beta to the degree of financial risk present during its estimation period. In the DCF analyses, I use the average stock price over the 15 trading days ending on the day that the earnings growth rate forecasts are obtained from Bloomberg.[6]

The market value of debt is estimated at its book value adjusted by the difference between the "Estimated Fair (market) Value" and the "carrying cost" of long-term debt reported in each company's 10-K.[7] The market value of preferred stock for the samples is set equal to its book value because the market values and book values do not differ much and because the percent of preferred stock in the capital structures of the sample companies is relatively small compared to the debt and common equity components.

[5] *Value Line* uses five years of historical data to estimate its forecasted betas.

[6] Forecasts were obtained on April 9, 2007 for all companies in the benchmark gas LDC sample.

[7] The book value of debt from Bloomberg includes all interest-bearing financial obligations that are not current and includes capitalized leases and mandatory redeemable preferred and trust preferred securities in accordance with FASB 150 effective June 2003. See Bloomberg definition of long-term debt for additional detail.

2. Market Costs of Debt and Preferred Equity

Q26. How do you estimate the current market cost of debt?

A26. The market cost of debt for each company in the DCF analysis is the current yield reported by Bloomberg for its index of public utility company bonds corresponding to the sample company's current debt rating as classified by S&P. The risk positioning analysis, on the other hand, uses the current yield of a utility bond that corresponds to the five-year average debt rating of each company so as to match consistently the horizon of information used by *Value Line* to estimate company betas.

Q27. How do you estimate the market cost of preferred equity?

A27. For each company with preferred stock, the cost of preferred equity for each company is set equal to the yield on an index of preferred stock as reported in the Mergent Bond Record corresponding to the S&P rating of that company's debt.

3. Risk-Free Interest Rate Forecast

Q28. How do you obtain the forecasts of the risk-free interest rates over the period the utility rates set here are to be in effect?

A28. I obtain these forecast rates using data provided by Bloomberg. In particular, I use the reported government debt yields from the "constant maturity series". This information is displayed in Panels A and B of Table No. MJV-9.

Q29. What values do you use for the short-term and long-term risk-free interest rates?

A29. I use a value of 3.8 percent for the short-term risk-free interest rate and a value of 4.9 percent for the long-term risk-free interest rate as the benchmark interest rates in the equity risk premium analyses. These forecasts are constructed by using historical yield curve data to find the long-run average implied term premia on government securities, and combining these with recent yield curve data. Details of their calculation can be found in the Workpapers to Table No. MJV-9.

C. COST OF EQUITY METHODS

Q30. How do you estimate the cost of equity for your sample companies?

A30. Recall the definition of the cost of capital from the outset of my testimony: *the expected rate of return in capital markets on alternative investments of equivalent risk*. My cost of capital estimation procedures address three key points implied by the definition:

1. Since the cost of capital is an expected rate of return, it cannot be directly observed; it must be inferred from available evidence.

2. Since the cost of capital is determined in capital markets (e.g., the New York Stock Exchange), data from capital markets provide the best evidence from which to infer it.

3. Since the cost of capital depends on the return offered by alternative investments of equivalent risk, measures of the risks that matter in capital markets are part of the evidence that needs to be examined.

Q31. How does the above definition help in cost of capital estimation?

A31. The definition of the cost of capital recognizes a tradeoff between risk and expected return - the security market line - plotted earlier in Figure 1. Cost of capital estimation methods take one of two approaches: (1) they try to identify a comparable-risk sample of companies and to estimate the cost of capital directly; or (2) they establish the location of the security market line and estimate the relative risk of the security, which jointly determine the cost of capital. In terms of Figure 1, the first approach focuses directly on the vertical axis, while the second focuses both on the security's position on the horizontal axis and on the position of the security market line.

The first type of approach is more direct, but ignores the wealth of information available on securities not thought to be of precisely comparable risk. The "discounted cash flow" or "DCF" model is an example. The second type of approach, sometimes known as "equity risk premium approach," requires an extra step, but as a result can make use of information on all securities, not just a very limited subset. The Capital Asset Pricing Model ("CAPM") is an example. While both approaches can work equally well if

conditions are right, one may be preferable to the other under other circumstances. In particular, approaches that rely on the entire security market line are less sensitive to deviations from the assumptions that underlie the model, all else equal. I examine both DCF and risk positioning approach evidence for the sample.

1. The Risk Positioning Approach

Q32. Please explain the risk positioning method.

A32. The risk positioning method estimates the cost of equity as the sum of a current interest rate and a company specific risk premium. It is therefore sometimes also known as the "risk premium" approach. This approach may sometimes be applied informally. For example, an analyst or Commission may check the spread between interest rates and what is believed to be a reasonable estimate of the cost of capital at one time, and then apply that spread to changed interest rates to get a new estimate of the cost of capital at another time.

More formal applications of the risk positioning approach take full advantage of the security market line depicted in Figure 1 - they use information on all securities to identify the security market line and derive the cost of capital for the individual security based on that security's relative risk. This reliance on the entire security market line makes the method less vulnerable to the kinds of problems that arise for the DCF method, which relies on one stock at a time. The risk positioning approach is widely used and underlies most of the current research published in academic journals on the nature, determinants and magnitude of the cost of capital.

Q33. How are the "more formal" applications of risk positioning approach implemented?

A33. The first step is to specify the current values of the benchmarks that determine the security market line. The second is to determine the security's or investment's relative risk. The third is to specify exactly how the benchmarks combine to produce the security market line, so the company's cost of capital can be calculated based on its relative risk.

All of these elements and how they relate are usefully formulated in the framework of the CAPM.

a) The Capital Asset Pricing Model

Q34. Please start with the CAPM, by describing the model.

A34. As noted above, modern models of capital market equilibrium express the cost of equity as the sum of a risk-free rate and a market risk premium. The CAPM is the longest-standing and most widely used of these theories. The CAPM states that the cost of capital for an investment, *s*, (e.g., a particular common stock) is given by the following equation:

$$k_s = r_f + \beta_s \times MRP \qquad (2)$$

where k_s is the cost of capital for investment *s*; r_f is the risk-free rate, β_s is the beta risk measure for the investment *s*; and *MRP* is the market risk premium.

The CAPM relies on the empirical fact that investors price risky securities to offer a higher expected rate of return than safe securities do. It says that the security market line starts at the risk-free interest rate (that is the return on a zero-risk security, the y-axis intercept in Figure 1, equals the risk-free interest rate). Further, it says that the risk premium over the risk-free rate equals the product of beta and the risk premium on a value-weighted portfolio of all investments, which by definition has average risk.

b) The Empirical Capital Asset Pricing Model

Q35. What other equity risk premium model do you use?

A35. Empirical research has long shown that the CAPM tends to overstate the actual sensitivity of the cost of capital to beta: low-beta stocks tend to have higher risk premia than predicted by the CAPM and high-beta stocks tend to have lower risk premia than predicted. A number of variations on the original CAPM theory have been proposed to

explain this finding, but this finding can also be used to estimate the cost of capital directly, using beta to measure relative risk without simultaneously relying on the CAPM.

The second model makes use of these empirical findings. It estimates the cost of capital with the equation, where α is the "alpha" adjustment of the risk-return line, a constant,

$$k_s = r_f + \alpha + \beta_s \times (MRP - \alpha) \quad (3)$$

and the other symbols are defined as above. I label this model the Empirical Capital Asset Pricing Model, or "ECAPM." The alpha adjustment has the effect of increasing the intercept but reducing the slope of the security market line in Figure 1 which results in a security market line that more closely matches the results of empirical tests.

Q36. Why is it appropriate for you to use the empirical CAPM?

A36. The CAPM has not generally performed well as an empirical model, but its shortcomings are directly addressed by the ECAPM. Specifically, the ECAPM recognizes the consistent empirical observation that the CAPM underestimates (overestimates) the cost of capital for low (high) beta stocks. In other words, the ECAPM is based on recognizing that the actual slope of the risk-return tradeoff is flatter than predicted and the intercept higher based upon repeated empirical tests of the CAPM. The alpha parameter (α) in the ECAPM adjusts for this fact. The difference between the CAPM and the type of relationship identified in the empirical studies is depicted in Figure 2.

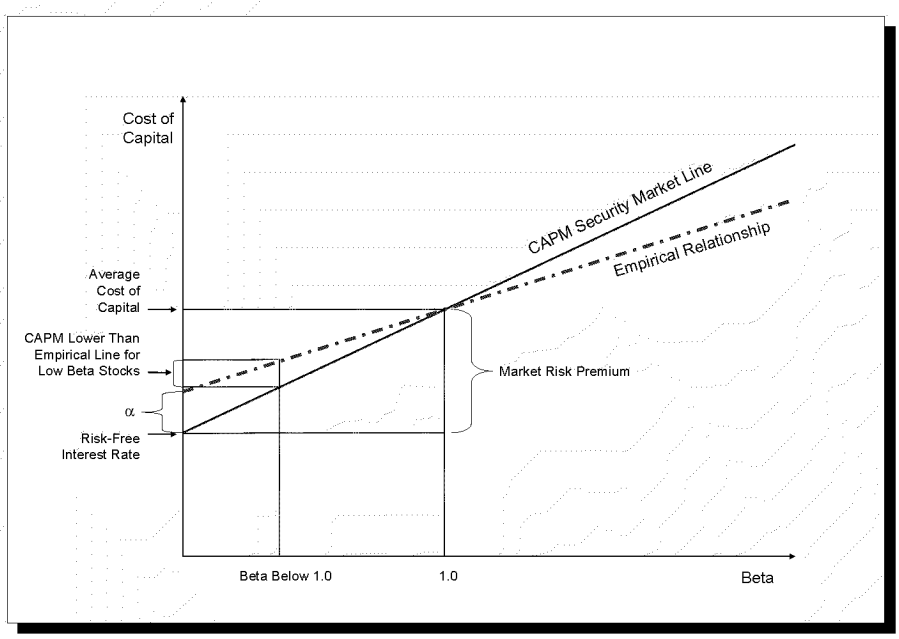

Figure 2: The Empirical Security Market Line

Research supports values for α of one to seven percent when using a short-term interest rate. I use baseline values of α of two percent for the short-term risk-free rate and 0.5 percent for the long-term risk-free rate. I also conduct sensitivity tests for different values of α. For the short-term risk-free rate I use values for α of one, two and three percent. For the long-term risk-free rate, the corresponding α values are zero, 0.5 and 1.5 percent. These values are lower than would be justified by the magnitude of the misestimation in the tests of the CAPM. I use lower values of α when using the long-term risk-free rate because use of a long-term risk-free rate incorporates some of the desired effect of using the ECAPM. That is, the long-term risk-free rate version of the security market line has a higher intercept and a flatter slope than the short-term risk-free version which is the version that has been extensively tested. Thus, it is likely that I do not need to make the same degree of adjustment when I use the long-term risk-free rate.

2. Discounted Cash Flow Method

Q37. Please describe the discounted cash flow approach.

A37. The DCF model takes the first approach to cost of capital estimation, i.e., to attempt to estimate the cost of capital in one step. The method assumes that the market price of a stock is equal to the present value of the dividends that its owners expect to receive. The method also assumes that this present value can be calculated by the standard formula for the present value of a cash flow stream:

$$P = \frac{D_1}{(1+k)} + \frac{D_2}{(1+k)^2} + \frac{D_3}{(1+k)^3} + \cdots + \frac{D_T}{(1+k)^T} \quad (4)$$

where "P" is the market price of the stock; "D_i" is the dividend cash flow expected at the end of period i; "k" is the cost of capital; and "T" is the last period in which a dividend cash flow is to be received. The formula just says that the stock price is equal to the sum of the expected future dividends, each discounted for the time and risk between now and the time the dividend is expected to be received.

Most DCF applications go even further, and make very strong (i.e., unrealistic) assumptions that yield a simplification of the standard formula, which then can be rearranged to estimate the cost of capital. Specifically, if investors expect a dividend stream that will grow *forever* at a steady rate, the market price of the stock will be given by a very simple formula,

$$P = \frac{D_1}{(k-g)} \quad (5)$$

where "D_1" is the dividend expected at the end of the first period, "g" is the perpetual growth rate, and "P" and "k" are the market price and the cost of capital, as before. Equation (5) is a simplified version of equation (4) that can be solved to yield the well known "DCF formula" for the cost of capital:

$$k = \frac{D_1}{P} + g$$
$$= \frac{D_0 \times (1+g)}{P} + g \qquad (6)$$

where "D_0" is the current dividend, which investors expect to increase at rate g by the end of the next period, and the other symbols are defined as before. Equation (6) says that if equation (5) holds, the cost of capital equals the expected dividend yield plus the (perpetual) expected future growth rate of dividends. I refer to this as the simple DCF model. Of course, the "simple" model is simple because it relies on very strong (i.e., very unrealistic) assumptions.

Q38. Are there other versions of the DCF models besides the "simple" one?

A38. Yes. The constant growth rate DCF model requires that dividends and earnings grow at the same rate for companies that earn their cost of capital on average.[8] It is inconsistent with the theory on which the model is based to have different growth rates in earnings and dividends over the period when growth is assumed to be constant. If the growth in dividends and earnings were expected to vary over some number of years before settling down into a constant growth period, then it would be appropriate to estimate a multistage DCF model. In the multistage model, earnings and dividends can grow at different rates, but must grow at the same rate in the final, constant growth rate period. A difference between forecasted dividend and earnings rates therefore is a signal that the facts do not fit the assumptions of the simple DCF model.

So, I consider a variant of the DCF model that relies on slightly less strong assumptions in that it allows for varying dividend growth rates in the near term before assuming a

[8] Why must the two growth rates be equal in a steady-growth DCF model? Think of earnings as divided between reinvestment, which funds future growth, and dividends. If dividends grow faster than earnings, there is less investment and slower growth each year. Sooner or later dividends will equal earnings. At that point, growth is zero because nothing is being reinvested (dividends are constant). If dividends grow slower than earnings, each year a bigger fraction of earnings are reinvested. That makes for ever faster growth. Both scenarios contradict the steady-growth assumption. So if you observe a company with different expectations for dividend and earnings growth, you know the company's stock price and its dividend growth forecast are inconsistent with the assumptions of the steady-growth DCF model.

perpetual growth rate beginning in year eleven. I use the forecast growth of GDP as the forecast of the long-term growth rate, i.e. year eleven on. This is a variant of the "multistage" DCF method.

Q39. What are the merits of the DCF approach?

A39. The DCF approach is conceptually sound if its assumptions are met, but can run into difficulty in practice because those assumptions are so strong, and hence so unlikely to correspond to reality. Two conditions are well known to be necessary for the DCF approach to yield a reliable estimate of the cost of capital: the variant of the present value formula that is used must actually match the variations in investor expectations for the growth of dividends, and the growth rate(s) used in that formula must match current investor expectations. Less frequently noted conditions may also create problems.

Q40. Do you agree that estimating the "right" dividend growth rate is the most difficult part for the implementation of the DCF approach?

A40. Yes. Finding the right growth rate(s) is the usual "hard part" of a DCF application. The original approach to estimation of *g* relied on average historical growth rates in observable variables, such as dividends or earnings, or on the "sustainable growth" approach, which estimates *g* as the average book rate of return times the fraction of earnings retained within the firm. But it is highly unlikely that these historical averages over periods with widely varying rates of inflation and costs of capital will equal current growth rate expectations. Although there has been relatively less turmoil in the natural gas LDC line of business, there have been a number of mergers and acquisitions in the industry. In addition, the price of natural gas has increased dramatically and has been much more volatile lately. Although most of the sample companies have fuel cost adjustment clauses, the increased volatility of gas prices has increased the uncertainty of the industry's earnings going forward. This uncertainty is also reflected in the accounting restatements in recent years as well as more involvement in non-regulated or non-gas activities. Therefore, because the underlying forecasts of earnings growth rates are less

reliable, the DCF estimates for the gas LDC sample are less reliable than they have been in the recent past.

IV. COST OF CAPITAL ESTIMATES

A. COMPANY BACKGROUND

Q41. Please describe Northwestern's South Dakota gas distribution assets?

A41. Northwestern serves approximately 83,900 customers in 59 communities in South Dakota with approximately 2,200 miles of distribution gas mains. Purchase adjustment clauses contained in South Dakota and Nebraska tariffs allow the Company to reflect increases or decreases in gas supply and interstate transportation costs on a timely basis, so the Company is generally allowed to pass natural gas prices through to customers. The Company does not have a weather adjustment clause in South Dakota.

B. SAMPLE SELECTION

Q42. How did you select your sample of natural gas LDCs?

A42. The goal was to create a sample of companies whose primary business is as a regulated natural gas LDC with business risk generally similar to that of NorthWestern's SD gas distribution operations. I considered the universe of 23 companies classified by the *Value Line Investment Survey Plus* as natural gas LDCs, and added Vectren Corporation to my sample because it is often viewed as a natural gas LDC. Vectren is involved in both gas and electric distribution activities, but now obtains a substantially amount of income from its gas distribution operations.[9] This company is also covered by *Value Line*, but is classified as an Electric Utility due to its regulated electric operations.

[9] Vectren Utility Holdings, Inc.'s 2006 10K reveals that about 45.4 percent of its income is from regulated gas distribution activities and 45.5 percent from regulated electric operations. Because it has a substantial amount of regulated electric activity, I exclude it from the sub-sample of companies I consider to be the most

Companies were first eliminated if their operating regions were outside of the continental USA. I then applied my standard selection criteria to narrow the sample to those companies likely to have reliable cost of equity estimates. This resulted in a benchmark sample of nine companies which are outlined in Table 1. NorthWestern Corporation has been added to Table 1 for comparison purposes. Additional details on the sample selection process can be found in Appendix B.

representative of the natural gas distribution line of business and to be most free of characteristics that may bias cost of equity estimates (see below).

1. The Gas LDC Sub-Sample

Q43. Why do you advocate summarizing the cost of capital estimates from a sub-sample of the gas LDC companies as well as for the full sample?

A43. Although the sample selection criteria are designed to screen out any company that has characteristics that may bias the cost of equity estimates, some of the sample companies are better than others. For example, although still investment grade, Southwest Gas is at the bottom of the scale of investment grade credit ratings and has a relatively low average equity thickness over the past five years – 40.1 percent compared to 61.8 percent for the remaining companies. Closer investigation shows that Southwest Gas's capital structure has been shifting rapidly toward equity over the last five years, with a level of about 50 percent over the most recent two years. This kind of instability suggests a potential reliability problem for estimates of this company's cost of capital. The Laclede Group's market cap of $688 million is a bit smaller than the average of the group, but with revenues of more than $1.5 billion, it is still a large company. In 2006, Piedmont Natural Gas restated some portions of its 2003-2005 financial reports. Although this can generally lead to less reliable estimates from the equity estimation models, the restatements were not caused by fraudulent activities but were due to an accounting error in the classification of hedging amounts. This type of reclassification would not be expected to change the value of the firm and prices did not show any erratic behavior in the period surrounding the announcement of this reclassification. A potential concern for the DCF estimates is that the industry has experienced a sustained level of merger and acquisition activity over the last five years that has implication for the stability of the industry necessary for the reliable application of the DCF model. Due to the concerns with the sample, I also report the results for a sub-sample of the gas LDC sample that consists of companies with no material data issues.

2. Relative Risk of the Sample and NorthWestern's SD Gas Utility

Q44. Could you please summarize the general characteristics of the companies in the sample and those of NorthWestern's SD operations?

A44. Yes. The sample consists of nine gas LDCs with generally similar risk characteristics to those of NorthWestern's SD operations. Like NorthWestern's SD operations, they all have fuel-cost adjustment clauses which either remove or significantly reduce their exposure to this risk. In their 10-Ks, all sample companies report that they engage in hedging activities to further reduce this risk. In addition, seven of the nine companies have weather adjustment clauses which NorthWestern does not have for its SD gas operations. NorthWestern is currently rated BB+ by S&P, and its S&P Business Profile is 5.[10]

[10] NorthWestern's SD gas operation does not have a separate S&P business profile rating.

Table 2: Risk Factors Summary for the Gas LDC Sample

Company Specific Risk Analysis

Company [1]	Fuel Cost Adjustment [2]	Weather Normalization [3]	Fuel Cost Hedging [4]	Storage Facilities [5]	S&P Business Profile [6]
Atmos Energy (GA, KS, KY, LA, TX, MS, TN, VA)	Yes	Yes	S & D	Yes	4
Laclede Group (MO)	Yes	NO	D	Yes	3
Northwest Natural Gas (WA, OR)	Yes	Yes	S & D	Yes	1
Piedmont Natural Gas (SC, TN, NC)	Yes	Yes	Yes	Yes	2
South Jersey Industries (NJ)	Yes	Incentive Prog.	D	Yes	na
Southwest Gas (AZ, NV, CA)	Yes	Yes	Fix & Var Price	Yes	3
WGL Holdings (DC, VA, MD)	Yes	Yes	D	No	3
AGL Resources (GA, FL, MD, NJ, TN, VA)	Yes	Yes	D	Yes	4
Vectren (IN, OH)	Yes	Yes	D	Yes	3
NorthWestern Corp† (MT, SD, NE)	**Yes**	**No**	**Fix & Var Price**	**Yes**	**5**

Notes and Sources: *All company 10-K sources are for the 2006 fiscal year.*

† Statistics specific to NorthWestern Corp's South Dakota regulated gas operations are unavailable.

[1] States of operation as reported in company 10-Ks for significant operations.

[2] Yes indicates a mechanism was reported in company 10-Ks, but different mechanisms exist by company and by state. If a mechanism exists, it generally allows for 100% recovery of prudent costs.

[3] Yes indicates a mechanism was reported in company 10-Ks, but different mechanisms exist by company and by state. South Jersey Industries reports participation in a Conservation incentive program.

[4] S - Storage D - Financial Derivatives Fix & Var Price - Price formulas are used to help mitigate weather risks. As reported in company 10-K's

[5] Information from company 10-Ks.

[6] S&P Business Profile as published on April 28, 2006 in S&P's *U.S. Utility and Power Ranking List*

Q45. How does the risk of the sample compare to the risk of NorthWestern's SD gas distribution operations?

A45. In general, the benchmark sample has comparable business risk to NorthWestern's SD gas operations. NorthWestern has a higher business risk profile than the sample, but that is for the company as a whole, and its unsecured credit rating is lower than the sample. These factors suggest that it is conservative to view the business risk of the sample as comparable to NorthWestern's SD gas operations.

C. COST OF CAPITAL AND COST OF EQUITY ESTIMATES

Q46. Please summarize the results of the risk positioning and DCF methodologies in estimating the average cost of capital for the benchmark sample and the implications for NorthWestern's SD operations' cost of equity?

A46. Table 3 below summarizes the risk positioning and DCF cost of equity estimates and the resulting sample average ATWACC estimates for the benchmark gas LDC sample, along with the implied cost of equity for NorthWestern's SD operations at a regulatory capital structure with 51.5 percent equity.

Q47. How did you determine a representative tax rate to use in your cost of capital estimation?

A47. South Dakota does not presently levy state corporate incomes taxes so I use the current federal corporate tax rate of 35 percent.

Q48. How were the cost of equity estimates derived from the risk positioning approach for the benchmark sample?

A48. I derive two sets of risk-positioning estimates, one using long-term forecasts of the risk-free rate and market risk premium, and one using short-term forecasts. The long-term

Table 3: Cost of Equity Estimates for NorthWestern's SD Gas Operations

Regulatory Capital Structure: *51.5% Equity / 48.5% Debt* *2007 Tax Rate:* *35%*

Sources and Notes:

* For the MJV US Gas LDC Sample , Risk Positioning data from Table No. MJV-12 and DCF data from Table No. MJV-6.

[1] , [2] The Gas LDC sample consists of Atmos Energy Corp, Laclede Group Inc, Northwest Natural Gas Co, Piedmont Natural Gas Co, South Jersey Industries Inc, Southwest Gas Corp, WGL Holdings Inc, AGL Resources Inc, and Vectren Corp. The sub-sample includes only Laclede Group Inc, Northwest Natural Gas Co, Piedmont Natural Gas Co, and WGL Holdings Inc.

[3] See Testimony, Section IV.C for details on Risk Positioning and DCF parameters used in estimates.

risk-free interest rate forecast is 4.9 percent and the corresponding estimated market risk premium is 6.5 percent. For the short-term risk-free rate, the corresponding values are 3.8 percent and 8.0 percent respectively.

The two risk positioning models (CAPM and ECAPM) are estimated for each horizon, with the long-term estimates utilizing two values of the ECAPM parameter (0.5% and 1.5%), and the short-term estimates utilizing three values of the ECAPM parameter (1%, 2%, and 3%). The risk positioning cost of equity estimates for the gas LDC sample are displayed in Table No. MJV-10, Panels A and B. The cost of equity estimates are subsequently combined with each company's estimated cost of debt and preferred equity to calculate the company's ATWACC using each company's market value capital structure. These calculations and the resulting sample average ATWACC for both the full sample and sub-sample are presented in Table No. MJV-11. Panels A-C of Table No. MJV-11 rely on the cost of equity estimates from the long-term version of the model,

while Panels D-G utilize the estimates from the short-term version of the model. The sample and sub-sample average ATWACC and corresponding cost of equity estimates at NorthWestern's 51.5 percent equity capital structure for each cost of equity estimation methods are displayed in Table No. MJV-12, Panels A and B. These results are summarized in Table 3 above.

Q49. What are the DCF estimates for the gas LDC sample?

A49. For each sample company, cost-of-equity estimates are calculated for the two versions of the DCF method. The DCF estimates for each company's cost of equity are displayed in Table No. MJV-6, Panel A (simple DCF) and Panel B (multistage DCF). The sample and sub-sample average ATWACCs for each method are calculated in Table No. MJV-7, Panels A and B, and are used in Table No. MJV-8, Panels A and B, to derive the resulting return on equity at NorthWestern's SD operations 51.5 percent equity capital structure. These results are summarized in Table 3 above, along with the sample and sub-sample average ATWACC numbers. Table 3 shows a cost of equity of 9.1 percent when using the simple DCF model but 9.7 percent from the multistage DCF model for the full sample. The corresponding results for the sub-sample are somewhat higher at 9.4 percent for the simple DCF and 10.3 percent for the multistage DCF. As discussed above, the sub-sample is likely to be a more reliable measure of the cost of capital for this industry. The industry has had more mergers and acquisition in recent years, and the companies in the industry have been more heavily involved in non-regulated activities such as gas marketing which has affected their earnings growth estimates. The variation in the estimates from the simple DCF compared to the multistage model, however, likely reflect the unique events in the industry and suggest that the simple DCF estimates are less reliable than the risk positioning estimates at this time.

V. CONCLUSIONS

Q50. What conclusions do you draw from the DCF estimates regarding the cost of equity for NorthWestern's SD gas operations?

A50. A review of Table No. MJV-6, Panel A shows that the simple DCF cost of equity estimates are highly variable and have a range of 3.6 percent, from a low of 6.5 percent for Vectren Corp. to a high of 10.1 percent for Atmos Energy Corp. The multistage estimates are much less variable, but still have a relatively wide range of 2.4 percent, from a low of 7.4 percent for Southwest Gas Corp. to a high of 9.8 percent for The Laclede Group Inc. The multistage DCF model adjusts for the fact that the earnings forecasts available for each company span only a five-year period, and in my view, the multistage DCF model provides more reliable results. Therefore, the most reliable of the DCF results for NorthWestern's SD gas operations is the 10.3 percent estimate for the multistage version of the DCF for the sub-sample. However, in my opinion, the variability of the DCF results demonstrates that the conditions for the completely reliable implementation of the DCF model do not obtain for the sample at this time. I therefore place little weight on the DCF results.

Q51. Do you have any general comments regarding the results of the risk positioning models?

A51. The estimates based upon the short-term risk-free rate are higher on average than the estimates using the long-term risk-free rate, partially because the yield curve is currently flat or slightly inverted, i.e., the yield on short-term Treasury bills exceeds the yield on long-term Treasury bonds. Table No. MJV-9, Panel A shows that 30-day Treasury bills are currently yielding 5.16 percent compared to only 4.90 percent for long-term Treasury bonds. The calculations displayed in Panel B, Workpaper #1 to Table No. MJV-9 show that the yield on long-term Treasury bonds has averaged about 150 basis points more than the yield on 30-day Treasury bills over the last 80 years. The increased yield on short-term Treasury bills reflects the efforts by the Federal Reserve ("Fed") to prevent the rate of inflation from increasing any further. If the Fed believes that inflation is not yet

contained, short-term rates are likely to increase further. On the other hand, if inflation is judged to be under control, short-term rates may decline as fears of recession replace those of inflation. Because of this uncertainty, I believe that the estimates using the long-term risk-free rate are more reliable at this time.

Q52. Please describe the results from the long-term version of the risk positioning model.

A52. Of those results, the CAPM values deserve the least weight, because this method does not adjust for the empirical finding that the cost of capital is less sensitive to beta than predicted by the CAPM (which my testimony considers by using the ECAPM). Conversely, the ECAPM numbers deserve the most weight, because this method adjusts for the empirical findings.

For the gas LDC sample, the cost of equity estimates using the long-term risk free rate and adjusted for a capital structure with a 51.5 percent equity ratio range from 11.1 to 11.4 percent for the full sample and from 11.5 to 11.8 for the sub-sample. The short-term estimates are 20 to 50 basis points higher on average than the long-term ones, ranging from 11.3 to 11.9 percent in the full-sample and 11.6 to 12.3 percent for the sub-sample. A review of the results in Panels A and B of Table No. MJV-10 also shows that the estimates are much less variable than for the DCF model. For example, considering the long-term ECAPM (0.5%) results in Panel A, one sees that the range is only 1.5 percent, from a low of 9.6 percent to a high of 11.1 percent with no significant outliers, whereas the range for the DCF model are 6.5 to 10.1 percent (simple DCF) and 7.4 to 9.8 percent (multistage DCF). (See Table No. MJV-6, Panels A and B.)

Q53. Given the results of the two models, what is your conclusion regarding the cost of equity for NorthWestern's SD gas distribution assets?

A53. I believe that NorthWestern's SD operations are of comparable business risk to the sample so the sample average cost of equity estimates adjusted for differences in finance risk represent a good estimate of the cost of equity for NorthWestern's SD operations. I make no adjustment to the cost of equity estimates for business risk differences between

the sample and NorthWestern. Focusing on the middle values in Table 3 for the gas LDC sample, the results from the long-term risk positioning model (ECAPM with $\alpha = 0.5$), the average ATWACC for the full sample is 7.7 percent, with a corresponding cost of equity estimate of 11.3 percent for the full sample and 7.9 and 11.6 percent for the sub-sample. Although I do not give much weight to the DCF estimates, I note that those estimates for the more reliable multistage model are lower at 10.3 percent for the sub-sample.

Based upon consideration of all of the sample evidence, the best point estimate for the cost of equity for NorthWestern's SD operations is 11¼ percent. Given the results of the cost of capital estimation models, this is a conservation estimate because this value is about ½ percent lower than the average risk positioning results for the sub-sample when using the long-term risk-free rate, but it is also about 1 percent higher than the multistage DCF estimates. As noted earlier, I do not believe that the DCF estimates are completely reliable for the industry at this time. In addition, the point estimate is about ½ percent lower than the results from the short-term version of the risk positioning model for the full sample. However, it is more correct to say that the estimates from the sample provide a range of values from a low of 10¾ percent to a high of 11¾ percent.

Q54. Does this conclude your testimony?

A54. Yes.

APPENDIX A

RESUMÉ

MICHAEL J. VILBERT **PRINCIPAL**

Michael Vilbert is an expert in cost of capital, financial planning and valuation who has advised clients on these matters in the context of a wide variety of investment and regulatory decisions. He received his Ph.D. in Financial Economics from the Wharton School of the University of Pennsylvania, an MBA from the University of Utah, an M.S. from the Fletcher School of Law and Diplomacy, Tufts University, and a B.S. degree from the United States Air Force Academy. He joined The Brattle Group in 1994 after a career as an Air Force officer, where he served as a fighter pilot, intelligence officer, and professor of finance at the Air Force Academy.

REPRESENTATIVE CONSULTING EXPERIENCE

- In a securities fraud case, Dr. Vilbert designed and created a model to value the private placement stock of a drug store chain as if there had been full disclosure of the actual financial condition of the firm. He analyzed key financial data and security analyst's reports regarding the future of the industry in order to recreate pro forma balance sheet and income statements under a variety of scenarios designed to establish the value of the firm.

- For pharmaceutical companies rebutting price-fixing claims in antitrust litigation, Dr. Vilbert was a member of a team which prepared a comprehensive analysis of industry profitability. The analysis replicated, tested and critiqued the major recent analyses of drug costs, risks and returns. The analyses helped develop expert witness testimony to rebut allegations of excess profits.

- For an independent electric power producer, Dr. Vilbert created a model that analyzed the reasonableness of rates and costs filed by a natural gas pipeline. The model not only duplicated the pipeline's rates, but it also allowed simulation of a variety of "what if" scenarios associated with cost recovery under alternative time patterns and joint cost allocations. Results of the analysis were adopted by the intervenor group for negotiation with the pipeline.

- For the CFO of an electric utility, Dr. Vilbert developed the valuation model used to support a stranded cost estimation filing. The case involved a conflict between two utilities over the responsibility for out-of-market costs associated with a power purchase

contract between them. In addition, he advised and analyzed cost recovery mechanisms that would allow full recovery of the stranded costs while providing a rate reduction for the company's rate payers.

- Dr. Vilbert has assisted in the preparation of testimony and the development of estimation models in numerous cost of capital cases for natural gas pipeline, water utility and electric utility clients before the Federal Energy Regulatory Commission ("FERC") and state regulatory commissions. These have spanned standard estimation techniques (e.g., Discounted Cash Flow and Risk Positioning models). He has also developed and applied more advanced models specific to the industries or lines of business in question, e.g., based on the structure and risk characteristics of cash flows, or based on multi-factor models that better characterize regulated industries.

- Dr. Vilbert has valued several large, residual oil-fired generating stations to evaluate the possible conversion to natural gas or other fuels. In these analyses, the expected pre- and post-conversion station values were computed using a range of market electricity and fuel cost conditions.

- For a major western electric utility, Dr. Vilbert helped prepare testimony that analyzed the prudence of QF contract enforcement. The testimony demonstrated that the utility had not been compensated in its allowed cost of capital for major disallowances stemming from QF contract management.

- Dr. Vilbert analyzed the economic need for a major natural gas pipeline expansion to the Midwest. This involved evaluating forecasts of natural gas use in various regions of the United States and the effect of additional supplies on the pattern of natural gas pipeline use. The analysis was used to justify the expansion before the FERC and the National Energy Board of Canada.

- For a Public Utility Commission in the Northeast, Dr. Vilbert analyzed the auction of an electric utilities purchase power agreements to determine whether the outcome of the auction was in the ratepayers' interest. The work involved the analysis of the auction procedures as well as the benefits to ratepayers of transferring risk of the PPA payments to the buyer.

- Dr. Vilbert led a team tasked to determine whether bridge tolls were "just and reasonable" for a non-profit port authority. Determination of the cost of service for the authority required estimation of the value of the authority's assets using the trended original cost methodology as well as evaluation of the operations and maintenance budgets. Investment costs, bridge traffic information and inflation indices covering a 75 year period were utilized to estimate the value of four bridges and a passenger transit line valued in excess of $1 billion.

- Dr. Vilbert helped a recently privatized railroad in Brazil develop an estimate of its revenue requirements, including a determination of the railroad's cost of capital. He also helped evaluate alternative rate structures designed to provide economic incentives to shippers as well as to the railroad for improved service. This involved the explanation and analysis of the contribution margin of numerous shipper products, improved cost analysis and evaluation of bottlenecks in the system.

- For a utility in the Southeast, Dr. Vilbert quantified the company's stranded costs under several legislative electric restructuring scenarios. This involved the evaluation of all of the company's fossil and nuclear generating units, its contracts with Qualifying Facilities and the prudence of those QF contracts. He provided analysis concerning the impact of securitizing the company's stranded costs as a means of reducing the cost to the rate payers and several alternative designs for recovering stranded costs.

- For a recently privatized electric utility in Australia, Dr. Vilbert evaluated the proposed regulatory scheme of the Australian Competition and Consumer Commission for the company's electric transmission system. The evaluation highlighted the elements of the proposed regulation which would impose uncompensated asymmetric risks on the company and the need to either eliminate the asymmetry in risk or provide additional compensation so that the company could expect to earn its cost of capital.

- For an electric utility in the Southwest, Dr. Vilbert helped design and create a model to estimate the stranded costs of the company's portfolio of Qualifying Facilities and Power Purchase contracts. This exercise was complicated by the many variations in the provisions of the contracts that required modeling in order to capture the effect of changes in either the performance of the plants or in the estimated market price of electricity.

- Dr. Vilbert helped prepare the testimony responding to a FERC request for further comments on the appropriate return on equity for electric transmission facilities. In addition, Dr. Vilbert was a member of the team that made a presentation to the FERC staff on the expected risks of the unbundled electric transmission line of business.

- Dr. Vilbert and Mr. Frank C. Graves, also of The Brattle Group, prepared testimony evaluating an innovative Canadian stranded cost recovery procedure involving the auctioning of the output of the province's electric generation plants instead of the plants themselves. The evaluation required the analysis of the terms and conditions of the long-term contracts specifying the revenue requirements of the plants for their entire forecasted remaining economic life and required an estimate of the cost of capital for the plant owners under this new stranded cost recovery concept.

- Dr. Vilbert served as the neutral arbitrator for the valuation of a petroleum products tanker. The valuation required analysis of the Jones Act tanker market and the supply and demand balance of the available U.S. constructed tanker fleet.

TESTIMONY

Direct and rebuttal testimony before the Alberta Energy and Utilities Board on behalf of TransAlta Utilities Corporation in the matter of an application for approval of its 1999 and 2000 generation tariff, transmission tariff, and distribution revenue requirement, October 1998.

Direct testimony before the Federal Energy Regulatory Commission on behalf of Central Maine Power in Docket No. ER00-982-000, December 1999.

Direct testimony before the Alberta Energy and Utilities Board on behalf of TransAlta Utilities Corporation for approval of its 2001 transmission tariff, May 2000.

Direct testimony before the Federal Energy Regulatory Commission on behalf of Mississippi River Transmission Corporation in Docket No. RP01-292-000, March 2001.

Written evidence, rebuttal, reply and further reply before the National Energy Board in the matter of an application by TransCanada PipeLines Limited for orders pursuant to Part I and Part IV of the *National Energy Board Act*, Order AO-1-RH-4-2001, May 2001, Nov. 2001, Feb. 2002.

Written evidence before the Public Utility Board on behalf of Newfoundland & Labrador Hydro - Rate Hearings, October 2001.

Direct testimony (with Bill Lindsay) before the Federal Energy Regulatory Commission on behalf of DTE East China, LLC in Docket No. ER02-1599-000, April 2002.

Direct and rebuttal reports before the Arbitration Panel in the arbitration of stranded costs for the City of Casselberry, FL, Case No. 00-CA-1107-16-L, July 2002.

Direct reports before the Arbitration Board for Petroleum products trade in the Arbitration of the Military Sealift Command vs. Household Commercial Financial Services, fair value of sale of the Darnell, October 2002.

Direct testimony and hearing before the Arbitration Panel in the arbitration of stranded costs for the City of Winter Park, FL, In the Circuit Court of the Ninth Judicial Circuit in and for Orange County, FL, Case No. C1-01-4558-39, December 2002.

Direct testimony before the Federal Energy Regulatory Commission on behalf of Florida Power Corporation, dba Progress Energy Florida, Inc. in Docket No. SC03-___-000, March 2003.

Direct report before the Arbitration Panel in the arbitration of stranded costs for the Town of Belleair, FL, Case No. 000-6487-C1-007, April 2003.

Direct and rebuttal reports before the Alberta Energy and Utilities Board in the matter of the Alberta Energy and Utilities Board Act, R.S.A. 2000, c. A-17, and the Regulations under it; in the matter of the Gas Utilities Act, R.S.A. 2000, c. G-5, and the Regulations under it; in the matter of the Public utilities Board Act, R.S.A. 2000, c. P-45, as amended, and the Regulations under it; and in the matter of Alberta Energy and Utilities Generic Cost of Capital Hearing, Proceeding No. 1271597, July 2003, November 2003.

Written evidence before the National Energy Board in the matter of the National Energy Board Act, R.S.C. 1985, c. N–7, as amended, (Act) and the Regulations made under it; and in the matter of an application by TransCanada PipeLines Limited for orders pursuant to Part IV of the *National Energy Board Act*, for approval of Mainline Tolls for 2004, RH-2-2004, January 2004.

Direct and rebuttal testimony before the Public Service Commission of West Virginia, on Cost of Capital for West Virginia-American Water Company, Case No 04-0373-W-42T, May 2004.

Direct and rebuttal testimony before the Federal Energy Regulatory Commission, on Energy Allocation of Debt Cost for Incremental Shipping Rates for Edison Mission Energy, Docket No. RP04-274-000, December 2004 and March 2005.

Direct testimony before the Arizona Corporation Commission, Cost of Capital for Paradise Valley Water Company, a subsidiary of Arizona-American Water Company, Docket No. WS-01303A-05, May 2005.

Written evidence before the Ontario Energy Board, Cost of Capital for Union Gas Limited, Inc., Docket No. EB-2005-0520, January 2006.

Direct and rebuttal testimony before the Pennsylvania Public Utility Commission, Return on Equity for Metropolitan Edison Company, Docket No. R-00061366 and Pennsylvania Electric Company, Docket No. R-00061367, April 2006 and August 2006.

Expert report in the United States Tax Court, Docket No. 21309-05, 34th Street Partners, DH Petersburg Investment, LLC and Mid-Atlantic Finance, Partners Other than the Tax Matters Partner, Petitioner, v. Commissioner of Internal Revenue, Respondent, July 28, 2006.

Direct and supplemental testimony before the Federal Energy Regulatory Commission, Docket No. ER06-427-003, on behalf of Mystic Development, LLC on the Cost of Capital for Mystic 8

and 9 Generating Plants Operating Under an Reliability Must Run Contract, August 2006 and September 2006.

Direct testimony before the Federal Energy Regulatory Commission, Docket No. ER07-46-000, on behalf of Northwestern Corporation on the Cost of Capital for Transmission Assets, October 2006.

Direct and rebuttal testimony before the Tennessee Regulatory Authority, Case No. 06-00290, on behalf of Tennessee American Water Company, on the Cost of Capital, November, 2006 and April 2007.

APPENDIX B

SELECTING THE GAS LDC SAMPLE AND USE OF MARKET VALUES

I. SAMPLE SELECTION AND THE SAMPLE'S CHARACTERISTICS 1

II. MARKET VALUE CAPITAL STRUCTURE, COSTS OF DEBT & COSTS OF PREFERRED EQUITY 5

I. SAMPLE SELECTION AND THE SAMPLE'S CHARACTERISTICS

Q1. How do you select the U.S. gas LDC sample?

A1. To select this sample, I started with the universe of publicly traded natural gas distribution utilities covered by *Value Line Investment Survey Plus*. This resulted in an initial group of 23 companies, to which I added Vectren Corporation because it is often viewed as a natural gas LDC. Vectren is involved in both gas and electric distribution activities, but more of its regulated assets are invested in the gas distribution operations.[1] This company is also covered by *Value Line*, but is classified as an Electric Utility due to its regulated electric operations.[2] I then eliminated companies by applying additional selection criteria designed to remove companies with unique circumstances which may bias the cost of capital estimates. The final sample consists of nine gas LDCs, from which I also consider a sub-sample of four companies with the fewest reliability concerns. Table No. MJV-2 reports the estimated share of total assets for each company devoted to regulated activities in 2006.

Q2. What are the other selection criteria you applied?

A2. Companies were first eliminated if their operating regions were outside of the continental USA. I then applied my standard selection criteria to narrow the sample to those companies likely to have reliable cost of equity estimates. Specifically, I eliminated all companies whose S&P bond rating as reported by Bloomberg was not investment grade, i.e., less than BBB-. To guard against measurement bias caused by "thin trading," I also restricted the sample to companies with total operating revenues greater than $300 million (USD) in 2006 as reported by Bloomberg.[3] Companies that had a large merger

[1] Vectren Utility Holdings, Inc.'s 2006 10K reveals that about 57 percent of its assets are regulated natural gas distribution assets and 37 percent are regulated electric assets. Because it has a substantial amount of regulated electric activity, I exclude it from the sub-sample of companies I consider to be the most representative of the natural gas distribution line of business and to be most free of characteristics that may bias cost of equity estimates.

[2] The 24 companies are from *Value Line Investment Survey Plus*, reviewed March 9, 2007.

[3] Data was reviewed during the first week of April 2007.

during the period January 2004 to April 2007 (i.e., just over the past three years) were also generally removed from the sample, although two companies which would otherwise not survive the process were included since their primary merger activity occurred in 2004. These two companies were Atmos Energy and AGL Resources, and they were subsequently excluded from a sub-sample of *cleanest* companies I also considered as part of my analysis. The screen for merger activity was primarily done by scanning each company's news history on Bloomberg and a search of company web pages.[4]

Finally, I required that the companies have historical data available from Bloomberg for the relevant period and had no dividend cuts or restatement of financial statements in the past five years, since the latter can be signs of financial distress.

Q3. Please elaborate on how companies were eliminated from your sample?

A3. Six companies were immediately eliminated due to a lack of long-term earnings per share ("EPS") growth rate estimates from Bloomberg. Of these, five also experienced dividend cuts and had either no bond rating or were rated less than BBB-. From the remaining companies, three were not rated and one had a rating of B+. Keyspan Corp. was eliminated for high levels of merger and acquisition activity ("M&A") and recent dividend cuts. UGI Corp. was removed for high levels of merger activity, and because it primarily sells propane which is not regulated. Southern Union was eliminated for its unusually high levels of M&A activity. Nicor Inc. was eliminated from the sample because it restated earnings for 1999-2001 and because it settled regulatory compliance issues with the Federal Energy Regulatory Commission ("FERC") in 2003.[5] Finally, New Jersey Resources was eliminated because of a very high percentage of revenues from other comprehensive income.

[4] Company web pages were searched in December 2003 for merger and acquisition activities during the 2001-2003 period, in July 2006 for merger and acquisition activities during the period 2004 through July 2006, and in December 2006 for the period August through December 2006.

[5] Nicor announced on October 29, 2002 that its earnings for 1999-2001 would be revised downwards by $15-35 million. March 4, 2003, Nicor released its restated earnings for 1999-2001 along with 2002 earnings.

Q4. Are there any issues with the remaining companies in your sample?

A4. Perhaps. Several companies in the sample engage in natural gas marketing activities (see Table 2 in the MJV Direct Testimony). [6] Given the turmoil of the energy trading markets, the companies' cost of capital estimates may be more volatile than those of more stable companies. Although still investment grade, Southwest Gas is at the bottom of the scale of investment grade credit ratings and has a relatively low average equity thickness over the past five years – 40.1 percent compared to 61.8 percent for the remaining companies. Closer investigation shows that Southwest Gas's capital structure has been shifting rapidly towards equity over the last five years, with a level of about 50 percent over the most recent two years. These factors suggest a potential reliability problem for estimates of this company's cost of capital at this time. The Laclede Group's market cap of $688 million is a bit smaller than the average of the group, but with revenues of more than $1.5 billion, it is still a large company. In 2006, Piedmont Natural Gas restated some portions of its 2003-2005 financial reports. Although this can generally lead to less reliable estimates from the equity estimation models, the restatements were not caused by fraudulent activities but were due to an accounting error in the classification of hedging amounts. This type of reclassification would not be expected to change the value of the firm and prices did not show any erratic behavior in the period surrounding the announcement of this reclassification. A potential concern for the DCF estimates is that the industry has experienced a sustained level of merger and acquisition activity over the last five years that has implication for the stability of the industry necessary for the reliable application of the DCF model. Due to the concerns with the sample, I also report the results for a sub-sample of the gas LDC sample that consists of companies with no material data issues.

[6] The percentages of regulated assets calculated for the samples are only estimates due to data reporting limitations.

Q5. Please compare the relative risk of the sample with respect to NorthWestern's SD operations.

A5. The sample consists of nine gas LDCs with generally similar risk characteristics to those of NorthWestern's SD gas operations (see Table 3 in the MJV Direct Testimony). Like NorthWestern's SD operations, they all have fuel-cost adjustment clauses which significantly reduce exposure to this risk. In their 10-Ks, all sample companies report that they engage in hedging activities to further reduce this risk. In addition, seven of the nine companies have weather adjustment clauses, but NorthWestern's SD operations does not have such a provision. The sample evidences a high degree of regulated activities, with the estimated share of regulated assets averaging about 87 percent across the companies in 2006 (see Table No. MJV-2). For the sub-sample, the percentage of regulated assets is even higher at 96 percent. As mentioned earlier in my direct testimony, Vectren Corp. earns a significant amount of its income from regulated electric activities despite being very active in the regulated gas LDC line of business. As such, it may be considered to be of slightly different business risk than the rest of the sample.[7]

Q6. What companies are in the sub-sample?

A6. The sub-sample consists of Laclede Group, Northwest Natural Gas, Piedmont Natural Gas and WGL Holdings. Vectren was eliminated because of its mix of both regulated natural gas and regulated electric operations. Atmos Energy and AGL Resources were eliminated because of M&A activities in 2004, and South Jersey Industries was eliminated from the sub-sample because of the accounting restatements.

Q7. What do you conclude from the comparison of the sample companies to NorthWestern's SD operations?

A7. I believe that the sample of regulated gas utility companies has business risk that is comparable on average to that of NorthWestern's SD gas operations.

[7] Vectron was excluded from the sub-sample for this reason.

II. MARKET VALUE CAPITAL STRUCTURE, COSTS OF DEBT & COSTS OF PREFERRED EQUITY

Q8. What capital structure information do you require?

A8. For reasons discussed in my written evidence and explained in detail in Appendix E, explicit evaluation of the market-value capital structures of the sample companies versus the capital structure used for rate making is vital for a correct interpretation of the market evidence. This requires estimates of the market values of common and preferred equity and debt, and the current market costs of preferred equity and debt.

Q9. How do you calculate the market-value capital structures of the sample companies?

A9. I estimate the capital structure for each company by estimating the market values of common equity, preferred equity and debt from publicly available data. The calculations are in Panels A to I of Table No. MJV-3.

The market value of equity is straightforward: the price per share times the number of shares outstanding. The market value of preferred is set equal to its book value because the portion of the capital structure financed with preferred equity is generally small. The market value of debt is estimated at the book value of debt reported by Bloomberg plus or minus the difference in the estimated fair (market) value and book value of long-term debt as reported in the companies' 10-Ks or annual reports.[8]

For purposes of assessing financial risk to common shareholders, I add an adjustment for short-term debt to the debt portion of the capital structure. This adjustment is used only for those companies whose short-term (current) liabilities exceed their short-term (current) assets. I add an amount equal to the minimum of the difference between short-term liabilities and short-term assets or the amount of short-term debt. The reason for this adjustment is to recognize that when current liabilities exceed current

[8] See Panels A through I in Table No. MJV-3 for details. The adjustment relies on the difference between the companies' self-reported fair value of long-term debt and the carrying value of the same line items. This information was obtained from the sample companies' annual reports.

assets, a portion of the companies long-term assets are being financed, in effect, by short-term debt.

The market value capital structure is calculated to be consistent with the time period over which the cost of capital is estimated for the sample. The capital structure is determined over the historical period over which the relevant risk positioning parameters were determined and as of the date analysts provide forward looking growth forecasts. Therefore, Table No. MJV-3 reports the market value capital structure at year end for the years ending 2002 - 2006. The output of these tables is the market equity-to-value, debt-to-value, and preferred equity-to-value ratios. The overall cost of capital calculation for the gas LDC risk positioning estimates rely on the average of the market value capital structure computed for the years 2002 through 2006 as shown in Table No. MJV-4. The results in columns [1]-[3] are used in the DCF model calculations, while columns [4]-[6] are for the risk positioning models.

Q10. How do you estimate the current market cost of preferred equity?

A10. For companies with preferred equity, the cost of preferred equity for each company was set equal to the yield on an index of preferred stock as reported in the Mergent Bond Record corresponding to the S&P rating of that company's debt. The yields from Mergent were as of March 10, 2007. In general, the average amount of preferred equity in the sample companies' capital structures is very small and frequently zero. No company has more than two percent on average.[9]

Q11. How do you estimate the current market cost of debt?

A11. The market cost of debt for each company in the DCF analysis is the current yield reported by Bloomberg for a public utility company bond corresponding to the sample company's current debt rating as classified by S&P. The risk positioning analysis, on the other hand, uses the current yield of a utility bond that corresponds to the five-year average debt rating of each company so as to match consistently the horizon of

[9] NorthWestern itself has no preferred securities in its regulatory capital structure.

information used by *Value Line* to estimate company betas. The current S&P debt ratings were obtained from Bloomberg.

Bloomberg reports that as of March 27, 2007, the average yield on A-rated Public Utility bonds was 5.85 percent, and 6.11 percent on average for BBB-rated Public Utility bonds.[10] (See Panel C of Workpaper #1 to Table No. MJV-11 for the yields on utility bonds and preferred stock by credit rating.) Calculation of the after-tax cost of debt uses the current federal corporate marginal tax rate of 35 percent, since South Dakota does not currently collect corporate level taxes.

[10] All companies in the U.S. gas LDC samples are either BBB or A rated except WGL Holdings which is AA-rated. The yield on AA-rated utility bonds is calculated as the yield on A-rated utility bonds minus ½ times the spread between the yield on BBB and A rated utility bonds.

TABLES AND WORKPAPERS

I. INTRODUCTION AND SUMMARY

Q1. Please state your name and address for the record.

A1. My name is Michael J. Vilbert. My business address is The Brattle Group, 44 Brattle Street, Cambridge, MA 02138, USA.

Q2. Please describe your job and your educational experience.

A2. I am a Principal of The Brattle Group, ("Brattle"), an economic, environmental and management consulting firm with offices in Cambridge, Washington, London, San Francisco and Brussels. My work concentrates on financial and regulatory economics. I hold a B.S. from the U.S. Air Force Academy and a Ph.D. in finance from the Wharton School of Business at the University of Pennsylvania.

Q3. What is the purpose of your testimony in this proceeding?

A3. I have been asked by Ohio Edison Company ("OE"), The Cleveland Electric Illuminating Company ("CEI") and The Toledo Electric Company ("TE"), (collectively, the "Companies" or the Ohio Electric Distribution Utilities ("Ohio EDUs")) to estimate the cost of equity that the Public Utilities Commission of Ohio (the "PUCO" or the "Commission") should allow the Ohio EDUs an opportunity to earn on the equity financed portion of their rate bases.

To accomplish this task, I estimate the overall cost of capital for a sample of regulated electric companies using the discounted cash flow ("DCF") and the risk positioning models. I then evaluate the relative risk of the Ohio EDUs compared to the sample companies to determine the recommended cost of equity for a regulatory capital structure with 49 percent equity, which is the percentage of equity in the Ohio EDUs' proposed capital structures in the filing for this proceeding.

Q4. Please summarize the parts of your background and experience that are particularly relevant to your testimony on these matters.

A4. Brattle's specialties include financial economics, regulatory economics, and the gas and electric industries. I have worked in the areas of cost of capital, investment risk and

related matters for many industries, regulated and unregulated alike, in many forums. I have testified or filed cost of capital testimony before the Federal Energy Regulatory Commission, the Arizona Corporation Commission, the Pennsylvania Public Utility Commission, the Public Service Commission of West Virginia, the Tennessee Regulatory Authority, the Public Service Commission of Wisconsin, the South Dakota Utilities Board, the California Public Utilities Board, the Canadian National Energy Board, Alberta Energy and Utilities Board, the Ontario Energy Board, and the Labrador & Newfoundland Board of Commissioners of Public Utilities. I have not previously testified before this Commission. Appendix A contains more information on my professional qualifications.

Q5. Please summarize how you approached this task.

A5. I review the evidence from a sample of regulated electric utilities which were selected to be of comparable business risk to the Ohio EDUs. My analyses consider cost of capital evidence from the risk positioning and discounted cash flow models, but I rely primarily on the risk positioning results because I do not believe that the DCF method is completely reliable at this time.

Specifically, I estimate the cost of equity for the companies in the sample group using both cost-of-equity estimation methods. For each cost-of-equity estimate, I combine this value with the sample company's market costs of debt and preferred stock to calculate each firm's overall cost of capital, i.e. its after-tax weighted-average cost of capital ("ATWACC"), using each company's market value capital structure as the weights. For each method of estimating the return on equity, I report the sample average ATWACC and the estimated cost of equity for this line of business at a capital structure with 49 percent equity. I thus present the cost of equity that is consistent with both the sample's market information and the Ohio EDUs' regulatory capital structures. (By "regulatory capital structure," I mean the capital structures that the Ohio EDUs utilize in their applications.[1])

[1] The capital structure that I customarily use in these analyses is based upon the long-term sources of capital, i.e., long-term debt, preferred equity and common equity. I do not use short-term debt because long-term

This method automatically avoids problems that can arise when an analyst focuses separately on the individual components (i.e., the cost of equity and the appropriate capital structure) of the overall cost of capital. The danger with that approach is that the estimated cost of equity from the sample may correspond to a very different level of financial risk than would exist at the regulated company's capital structure. The result could be an inconsistency between the allowed return on equity and the financial risk inherent in the regulatory capital structure.

Q6. Why do you believe that the DCF model is less reliable for this industry at this time than the risk positioning model?

A6. Results for the DCF model depend critically on the estimate of the dividend growth rate. A one percent error in the estimate of the growth rate results in a greater than one percent error in the cost of equity estimates. The move toward a restructured industry featuring greater competition among providers of generation services has stalled and the future structure of the electric industry remains in doubt. The legislature in Virginia has approved legislation that effectively ends electric deregulation in the Commonwealth,[2] and the legislature in Illinois proposed a one-year extension of the rate cap on the cost of power that is less than the current market price of power.[3] Natural gas prices have increased dramatically and have been much more volatile lately relative to just a few years ago. Although most of the companies in the sample have fuel cost adjustment clauses, the increased volatility of gas prices has increased the uncertainty of the industry's earnings going forward. These facts are not a description of an industry that could be characterized as stable with earnings and dividends likely to grow at a constant rate over the foreseeable future, but that is precisely the condition necessary for the reliable implementation of the DCF model.

---

assets are not generally financed with short-term debt. In the case of the Ohio EDUs, there is no preferred stock.

[2] H.B. 3068 and S.B. 1416 was approved by the General Assembly on April 4, 2007 and are expected to become law on July 1. See, for example, www.dom.com/about/companies/vapower/rereg.jsp.

[3] See http://www.ilga.gov/legislation/billstatus.asp? DocNum=1592&GAID=9&GA=95, &DocTypeID=SB&LegID=29675&SessionID=51

The DCF model results display a greater spread and are more variable and less reliable than those based upon the risk positioning model; however, I provide results using the DCF method, because it is a method that has been relied upon by commissions frequently in the past. In addition, results from the DCF model serve as a check on the results from the equity risk positioning approach.

Q7. What are the results for the DCF model?

A7. Results from the simple DCF model and for the more reliable multistage model are set out in the accompanying tables. (See Table No. MJV-6, Panel A - simple DCF and Panel B - multistage DCF) After properly adjusting for financial risk, the sample average for the simple DCF model is 13.4 percent and for the multistage DCF model is 11.2 percent. (See Table No. MJV-8) I believe that these highly variable DCF results demonstrate that the conditions necessary for a completely reliable implementation of the DCF model do not obtain at this time.

Q8. What are the results for the risk positioning model?

A8. The sample average risk positioning results, adjusted for differences in financial risk, range from a low of 11.8 to 12.1 percent for the full sample when using the long-term risk-free rate. I also report results for the risk positioning model using the short-term risk-free rate, but I place very little weight on those estimates in this proceeding. (See Table No. MJV-12)

Q9. You mentioned the importance of considering financial risk when evaluating the results of the models. Please explain how you adjust for financial risk.

A9. Both the DCF and the risk positioning models rely on market data to estimate the cost of equity for the sample companies. That cost of equity estimate captures both the business risk and the financial risk of the assets. Business risk is the risk that the company would have if it were financed entirely with equity. Financial risk is the additional risk carried by the equity holders when debt is used to finance some of the assets. The more debt that is used by a company, the riskier the company's equity becomes. As explained in more detail below, the procedures I use consider both the business risk and the financial risk of

the sample companies in comparison to the Ohio EDUs in determining my recommended cost of equity.

Q10. What is your conclusion on the market-determined cost of capital for the Ohio EDUs based upon the results from the sample of regulated companies you selected?

A10. The best point estimate of the cost of equity for the Ohio EDUs is 11¾ percent for a capital structure with 49 percent equity, but it is more correct to say that the sample results indicate a range for the cost of equity estimates from 11¼ to 12¼ percent. The corresponding midpoint of the range of the overall cost of capital estimates, i.e., the ATWACC, for the benchmark sample companies is 7⅞ percent with a range of 7⅜ to 8⅜ percent. Note, that I specify a plus or minus ½ percent range for the return on equity and specify the point estimate to the nearest ¼ percent because I do not believe that it is possible to estimate the cost of equity more precisely than that.

Q11. How is your testimony organized?

A11. *Section II* formally defines the cost of capital and touches on the principles relating to the cost of capital and capital structure for a business. *Section III* presents the methods used to estimate the cost of capital for the benchmark sample and the associated numerical analyses, and explains the basis of my conclusions for the benchmark sample's returns on equity and overall costs of capital. *Section IV* presents the results of these methods applied to the benchmark sample group, and presents the costs of equity implied by the results. My conclusions on the cost of equity for the Ohio EDUs are presented in *Section V*. Appendix B provides additional details on the selection of the sample and the calculation of the market value capital structures of the sample companies. Appendices C and D support *Sections III and IV* with additional details on the risk positioning model and DCF approach, respectively, including the details of the numerical analyses. Appendix E discusses the effect of debt on the cost of equity in more detail.

II. COST OF CAPITAL THEORY

A. THE COST OF CAPITAL AND RISK

Q12. Please formally define the "Cost of Capital."

A12. The cost of capital can be defined as *the expected rate of return in capital markets on alternative investments of equivalent risk*. In other words, it is the rate of return investors require based on the risk-return alternatives available in competitive capital markets. The cost of capital is a type of opportunity cost: it represents the rate of return that investors could expect to earn elsewhere without bearing more risk. "Expected" is used in the statistical sense: the mean of the distribution of possible outcomes. The terms "expect" and "expected" in this testimony, as in the definition of the cost of capital itself, refer to the probability-weighted average over all possible outcomes.

The definition of the cost of capital recognizes a tradeoff between risk and return that is known as the "security market risk-return line," or "security market line" for short. This line is depicted in Figure 1. The higher the risk, the higher is the cost of capital. A version of Figure 1 applies for all investments. However, for different types of securities, the location (i.e., the intercept and the slope) of the line may depend on corporate and personal tax rates.

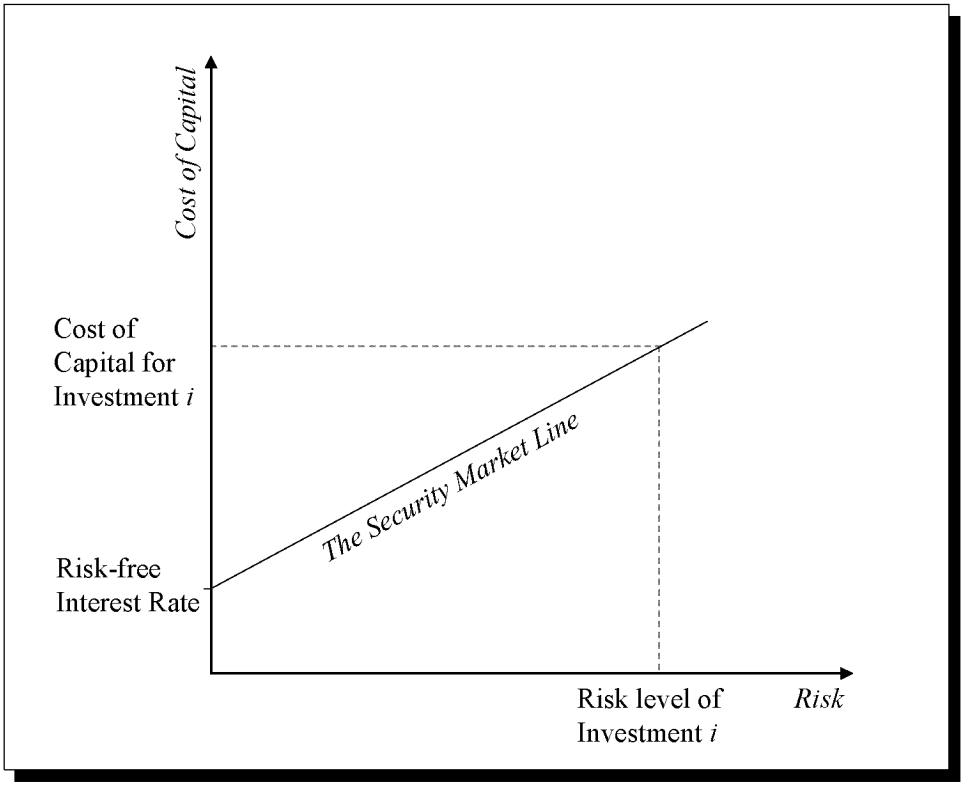

Figure 1: The Security Market Line

Q13. Why is the cost of capital relevant in rate regulation?

A13. It has become routine in U.S. rate regulation to accept the "cost of capital" as the right expected rate of return on utility investment.[4] That practice is normally viewed as consistent with the U.S. Supreme Court's opinions in *Bluefield Waterworks & Improvement Co. v. Public Service Commission*, 262 U.S. 678 (1923), and *Federal Power Commission v. Hope Natural Gas*, 320 U.S. 591 (1944).

From an economic perspective, rate levels that give investors a fair opportunity to earn the cost of capital are the lowest levels that compensate investors for the risks they bear. Over the long run, an expected return above the cost of capital makes customers overpay for service. Regulatory commissions normally try to prevent such outcomes, unless there are offsetting benefits (e.g., from incentive regulation that reduces future costs). At the same time, an expected return below the cost of capital does a disservice not just to

[4] A formal link between the cost of capital as defined by financial economics and the right expected rate of return for utilities is established by Stewart C. Myers, "Application of Finance Theory to Public Utility Rate Cases," *The Bell Journal of Economics and Management Science*, 3:58-97 (Spring 1972).

investors but, importantly, to customers as well. In the long run, such a return denies the company the ability to attract capital, to maintain its financial integrity, and to expect a return commensurate with that of other enterprises attended by corresponding risks and uncertainties.

More important for customers, however, are the economic issues an inadequate return raises for them. In the short run, deviations of the expected rate of return on the rate base from the cost of capital may seemingly create a "zero-sum game"-- investors gain if customers are overcharged, and customers gain if investors are shortchanged. But in fact in the short run, such action may adversely affect the utility's ability to provide stable and favorable rates because some potential efficiency investments may be delayed or because the company is forced to file more frequent rate cases. In the long run, inadequate returns are likely to cost customers -- and society generally -- far more than is gained in the short run. Inadequate returns lead to inadequate investment, whether for maintenance or for new plant and equipment. The costs of an undercapitalized industry can be far greater than the short-run gains from shortfalls in the cost of capital. Moreover, in capital-intensive industries (such as the electric utility industry), systems that take a long time to decay cannot be fixed overnight. Thus, it is in the customers' interest not only to make sure the return investors expect does not exceed the cost of capital, but also to make sure that it does not fall short of the cost of capital, either.

Of course, the cost of capital cannot be estimated with perfect certainty, and other aspects of the way the revenue requirement is set may mean investors expect to earn more or less than the cost of capital even if the allowed rate of return equals the cost of capital exactly. However, a commission that sets rates so investors expect to earn the cost of capital on average treats both customers and investors fairly, and acts in the long-run interests of both groups.

Q14. If a commission sets the allowed return equal to the cost of capital is that sufficient to insure that the regulated company has a fair opportunity to earn its cost of capital?

A14. In general, yes, but there are circumstances in which it would not. Specifically, if the regulated company faces a substantial level of asymmetric risk, the regulated company may not expect to earn its cost of capital on average. Asymmetric risk for a regulated company exists when the possibility of a large negative outcome is not balanced by the possibility of a corresponding positive outcome. For example, if a regulated electric distribution company serving as provider of last resort were unable to pass through to customers the full costs of acquiring power due a rate cap, setting the allowed return equal to the cost of capital would not provide a fair opportunity to earn it. This is the situation currently faced by the utilities in Illinois with the proposed extension of a price cap that is less than the current price of power. In such a situation, the regulated company will expect to earn less than its cost of capital if there is any possibility that the market cost of power exceeds the rate cap. The solution would be to either remove the source of the asymmetric risk (e.g., the price cap) or set the allowed return high enough so that the regulated company can again expect to earn its cost of capital.

Q15. Does asymmetric risk affect the cost of capital?

A15. Maybe. In general, asymmetric risk definitely affects the probability that a regulated utility would expect to earn its allowed return, but it may not affect its cost of capital. The cost of capital would be affected if the asymmetric risk were correlated with changes in the capital market. However, if a regulated utility faces substantial asymmetric risk, the allowed return on equity would have to be increased in order for the regulated company to expect to earn its cost of capital on average.

Q16. Please expand the discussion how a regulator can correct the effect of asymmetric risk?

A16. There are two ways to correct asymmetric risk. The first is to add a premium to the allowed rate of return on equity for the regulated company so that it can again expect to earn its cost of capital. The second method is to remove the source of the asymmetric risk which in this example means allowing full recovery of the cost of providing POLR

service to the regulated company's customers. I believe that removing the source of the asymmetric risk is a more efficient and cost effective way to establish the conditions necessary for the regulated company to expect to earn its cost of capital.

Q17. Is this an issue for the Ohio EDUs at this time?

A17. Perhaps. Consider the following example on recovery of the costs of providing POLR service. If for any reason the Ohio EDUs did not expect to recover fully the costs of providing POLR service to their rate payers, they would face an asymmetric risk situation. Because they would earn, at best, an inadequate return for providing the POLR service, the Ohio EDUs would not expect to earn their allowed return on average. In order to provide the Companies a fair opportunity to earn their allowed return, the Commission would either have to remove the source of asymmetry or add a premium to the allowed rate of return. The premium required in this example is a function of the two things: first, the size of the expected loss due to incomplete recovery of the cost of providing POLR service to meet the needs of customers and second, the amount of rate base that is financed with equity. The calculation is to divide the expected loss by the amount of equity.

B. BUSINESS RISK & FINANCIAL RISK: CAPITAL STRUCTURE AND THE COST OF EQUITY

Q18. Please explain briefly the difference between business risk and financial risk.

A18. Business risk is the risk of a company from its line of business if it used no debt financing. When a firm uses debt to finance its assets, the business risk of the assets is shared between the debt holders and the equity holders, but the equity holders bear more of the risk because debt holders have a prior claim on the company's cash flows. Equity holders are residual claimants, which simply means that equity holders get paid last. In other words, the use of debt imposes financial risk on the equity holders. Therefore, the goal of selecting a sample is to choose companies whose business risk is judged to be comparable to the Ohio EDUs.

Q19. Please explain why it is necessary to report the cost of equity adjusted for capital structure.

A19. Briefly, rate regulation in North America tends to focus on the components of the overall cost of capital, and in particular, on what the "right" cost of equity and capital structure should be. Frequently, there is no consideration of whether the financial risks of the sample companies differ among themselves or differ from the regulated company. The cost of equity estimated using the standard models (e.g., the DCF model or the risk positioning model) reflects both the business and financial risk of the sample companies. However, the overall cost of capital depends primarily on the business the firm is in, i.e., business risk, while the costs of the debt and equity components depend not only on this business risk alone but also on the distribution of revenues between debt and equity, i.e. financial risk. The overall cost of capital is thus the more basic concept. As I explain in Appendix C, the overall cost of capital is constant within a broad middle range of values of capital structures, but the distribution of the costs and risks among debt and equity is not. Appendix D sets out the principles and procedures on which I rely.

C. IMPLICATIONS FOR ANALYSIS

Q20. Please explain the implications of the relationship between capital structure and the cost of equity in your testimony.

A20. The risk equity holders carry, and therefore the cost of equity, depends on the capital structure. As leverage increases, financial risk increases, and hence the required return on equity increases. An approach that estimates the cost of equity for each of the sample firms without explicit consideration of the market value capital structure (i.e., the financial risk) underlying those costs risks material errors. The costs of equity of the sample companies at their actual market-value capital structures do not necessarily reflect the same degree of financial risk as faced by equity holders in the regulated company, and thus could lead to an unfair rate of return if the sample's cost of equity estimate were simply and mechanically applied to the regulated company's capital structure. I avoid this problem by calculating each sample company's ATWACC using its market value capital structure. Using the sample's average overall cost of capital (i.e., the average of the sample companies' ATWACCs) as an estimate of the Ohio EDUs' cost of capital, I

then determine the corresponding return on equity at the Ohio EDUs' filed regulatory capital structures for the Ohio EDUs as sponsored by Mr. James F. Pearson. This procedure ensures that the capital structure (i.e., financial risk) and the estimated cost of equity are consistent with the market derived sample information.

In the following analyses, I estimate the cost of equity for each of the sample firms using the DCF and risk positioning estimation methods. I use each company's estimated cost of equity along with the Ohio EDUs' estimated 2008 marginal tax rate and each sample company's cost of debt and market-value capital structure to estimate the company's overall cost of capital.[5] I then calculate the sample's average overall cost of capital for each equity estimation method. Using the procedure discussed above, I then determine the cost of equity at the Ohio EDUs' regulated capital structure that is consistent with the sample's overall cost of capital information for each estimation method.

Q21. To assess the magnitude of financial risk for a rate regulated company, should you use the market-value or the book-value capital structure?

A21. The market-value capital structure is the relevant quantity for analyzing the cost of equity evidence, which is based on market information.

Q22. Has the need to use market-value capital structures to estimate the cost of equity been widely recognized in the academic community?

A22. Yes. The need to use market-value capital structures to analyze the effect of debt on the cost of equity has been recognized in the financial literature for a long time. For example, the initial reconciliation of the Modigliani-Miller theories of capital structure with the Capital Asset Pricing Model, in Robert S. Hamada, "Portfolio Analysis, Market Equilibrium and Corporate Finance," The Journal of Finance 24: 13-31 (March 1969) works with market-value capital structures. For a more recent presentation of the concept, see, for example, Richard A. Brealey, Stewart C. Myers, and Franklin Allen, *Principles of Corporate Finance*, New York: McGraw-Hill/Irwin 8th ed. (2006) pp. 503-06. Book values may be relevant for some issues, e.g., for covenants on individual bond issues, but

[5] The lowest marginal tax rate of the three Ohio EDUs is used to provide conservative cost of equity numbers. This is discussed in *Section IV.C* below.

as explained in the text, market values are the determinants of the impact of debt on the cost of equity.

Q23. Is the use of market values to calculate the impact of capital structure on the risk of equity incompatible with use of a book-value rate base for a regulated company?

A23. No, no more than it is incompatible to use market-based cost of equity estimation methods (such as DCF or the risk positioning model) with a book value rate base. That is, the cost of capital is the fair rate of return on regulatory investment (i.e., rate base) for both investors and customers. Most regulatory jurisdictions in North America measure the rate base using the net book value of assets, not current replacement value or historical cost trended for inflation, but the jurisdictions still apply market-derived measures of the cost of equity to that net book value rate base.

The issue here is "what level of risk is reflected in that cost of equity estimate?" That equity risk level depends on the sample company's market-value capital structure, not its book-value capital structure. *That risk level would be different if the sample company's market-value capital structure exactly equaled its book-value capital structure, so the estimated cost of equity would be different, too.*

Q24. Please sum up the implications of this section.

A24. The market risk, and therefore the cost of equity, depends directly on the market-value capital structure of the company or asset in question. It therefore is impossible to compare validly the measured costs of equity of different companies without taking capital structure into account. Capital structure and the cost of equity are unbreakably linked, and any effort to treat the two as separate and distinct questions violates both everyday experience (e.g., with home mortgages as shown in the extended example in Appendix E) and basic financial principles.

Q25. How should a cost of capital analyst implement this principle?

A25. As discussed further in Appendix E, there has been a great deal of financial research on the effects of capital structure on the value of the firm. One of the key conclusions that results from the research is that no narrowly defined optimal capital structure exists within industries, although the typical range of capital structures does vary among

industries.[6] Instead, there is a relatively wide range of capital structures within any industry in which fine-tuning the debt ratio makes little or no difference to the value of the firm, and hence to its overall after-tax cost of capital.

Accordingly, analysts should treat the market-value weighted average of the cost of equity and the after-tax current cost of corporate debt, or the "ATWACC" for short,[7] as constant within a broad middle range of capital structures for the industry. Sample evidence should be analyzed to determine the sample's average ATWACC, which can be compared across different firms or industries. The economically appropriate cost of equity for a regulated firm is the quantity that, when applied to the *regulatory* capital structure, produces the same ATWACC. That value is the cost of equity that the sample would have had, estimation problems aside, if the sample's market-value capital structure had been equal to the regulatory capital structure in question.

Q26. Can you provide an example of the calculation of the cost of equity consistent with the market-determined estimate of the sample's average overall cost of capital?

A26. Yes. Consider the following equation to calculate the ATWACC:[8]

$$ATWACC = r_D \times (1 - T_C) \times D + r_E \times E \qquad (1)$$

where r_D = market cost of debt,
r_E = market cost of equity,
T_C = corporate income tax rate,
D = percentage of debt in the capital structure, and
E = percentage of equity in capital structure.

[6] An exception is that very high-risk industries should avoid debt entirely, which makes their optimal capital structure zero percent debt.

[7] This quantity typically is called the "weighted-average cost of capital" or "WACC" in finance textbooks. The textbook WACC equals the *market*-value weighted average of the cost of equity and the *after-tax*, *current* cost of debt. However, rate regulation in North America has a legacy of working with another, and very different, weighted-average cost of capital, the *book*-value weighted average of the cost of equity and the *before-tax*, *embedded* cost of debt. Accordingly, in regulatory settings it's useful to refer to the textbook WACC as the "ATWACC," or "after-tax weighted-average cost of capital." I follow that practice here.

[8] Note that this equation assumes that only debt and equity are in the capital structure, but one can add preferred equity to the equation if appropriate.

The cost of equity consistent with overall cost of capital estimate (ATWACC), the market cost of debt and equity, the marginal corporate income tax rate and the amount of debt and equity in the capital structure can be determined by solving equation (1) for r_E.

III. COST OF CAPITAL METHODOLOGY

Q27. How is this section of your testimony organized?

A27. As noted in Section II, I estimate the cost of capital using a sample of comparable risk companies. This section first outlines the steps involved in selecting the benchmark sample, in determining the market-value capital structures, and in estimating the sample companies' costs of debt. It then turns to the procedures for estimating the cost of equity and describes the two cost of equity estimation methodologies used in this testimony, the DCF method and the risk positioning approach. These are the foundations of my cost of capital calculations which I present in the following section and which I use to derive a recommended cost of equity for the Ohio EDUs at their regulatory capital structure.

A. SAMPLE SELECTION

Q28. How do you select the benchmark sample of regulated electric utilities?

A28. The overall cost of capital for a part of a company depends on the risk of the business in which the part is engaged, not on the overall risk of the parent company on a consolidated basis. According to financial theory, the overall risk of a diversified company equals the market-value-weighted average of the risks of its components.

Estimating the cost of capital for the Ohio EDUs' regulated assets is the subject of this proceeding. The ideal sample would be a number of publicly traded "pure play" companies that distribute electricity and have a requirement to serve as providers of last resort (POLR). "Pure Play" is an investment term referring to companies with operations only in one line of business. Publicly traded firms, firms whose shares are freely traded on stock exchanges, are ideal because the best way to infer the cost of capital is to examine evidence from capital markets on companies in the given line of business.

In this case, a sample of companies whose operations are concentrated solely in the regulated distribution portion of the electric industry would be ideal. Unfortunately, the available sample of pure play electric distribution companies in the U.S. is too small for a reliable sample. Instead, I start with the companies listed as electric utilities in *Value Line*. I then apply my standard selection procedures which require, for example, that data from S&P or Moody's, *Value Line*, I/B/E/S and Bloomberg be available for all sample companies. Moreover, the companies must have a high percentage of revenues from regulated operations, no significant merger activity in the previous five years, and no recent dividend cuts or other activity that could cause the growth rates or beta estimates to be biased.

B. CAPITAL STRUCTURE & THE COST OF DEBT

1. Market-Value Capital Structure

Q29. What capital structure information do you require?

A29. For reasons discussed in Appendix E, explicit evaluation of the market-value capital structures of the sample companies is vital for a correct interpretation of the market evidence on the return on equity. This requires estimates of the market values of common equity, preferred equity and debt, and the current market costs of preferred equity and debt.

Q30. Please describe how you calculate the market values of common equity, preferred equity and debt.

A30. I estimate the capital structure for each sample company by estimating the market values of common equity, preferred equity and debt from the most recent publicly available data. The details are in Appendix B.

Briefly, the market value of common equity is the price per share times the number of shares outstanding. For the risk positioning approach, I use the last five trading days of each year to calculate the market value of equity for the year. I then calculate the average capital structure over the corresponding five-year period used to estimate the "beta" risk

measures for the sample companies.[9] This procedure matches the estimated beta to the degree of financial risk present during its estimation period. In the DCF analyses, I use the average closing stock price over the 15 trading days ending on the day that the earnings growth rate forecasts are obtained from Bloomberg.[10]

The market value of debt is estimated at its book value adjusted by the difference between the "estimated fair (market) Value" and the "carrying cost" of long-term debt reported in each company's 10-K.[11] The market value of preferred stock for the samples is set equal to its book value because the market values and book values do not differ much and because the percent of preferred stock in the capital structures of the sample companies is relatively small compared to the debt and common equity components.

2. Market Costs of Debt and Preferred Equity

Q31. How do you estimate the current market cost of debt?

A31. The market cost of debt for each company is set equal to the yield on an index of public utility bonds that have the same credit rating, and the yield is reported by Bloomberg's for an index of public utility company bonds with the same S&P rating. The DCF analyses use the current credit rating whereas the risk positioning analyses use the current yield of a utility bond that corresponds to the five-year average debt rating of each company so as to match consistently the horizon of information used by *Value Line* to estimate company's beta.

Q32. How do you estimate the market cost of preferred equity?

A32. For each company with preferred stock, the cost of preferred equity for each company is set equal to the yield on an index of preferred stock as reported in the Mergent Bond Record corresponding to the S&P rating of that company's debt.

---

[9] *Value Line* uses five years of historical data to estimate its forecasted betas.

[10] Forecasts were obtained on March 20, 2007 for all companies in the benchmark sample.

[11] The book value of debt from Bloomberg includes all interest-bearing financial obligations that are not current and includes capitalized leases and mandatory redeemable preferred and trust preferred securities in accordance with FASB 150 effective June 2003. See Bloomberg definition of long-term debt for additional detail.

3. Risk-Free Interest Rate Forecast

Q33. What is the risk-free rate?

A33. The risk-free rate is the interest rate that can be earned with certainty. A common measure of this rate is the return on the government's Treasury bills and bonds. This rate is usually significantly below the rate which other borrowers pay for debt.

Q34. How do you obtain the forecasts of the risk-free interest rates over the period the utility rates set here are to be in effect?

A34. I obtain these forecast rates using data provided by Bloomberg. In particular, I use the reported government debt yields from the "constant maturity series". This information is displayed in Panels A and B of Table No. MJV-9.

Q35. What values do you use for the short-term and long-term risk-free interest rates?

A35. I use a value of 3.8 percent for the short-term risk-free interest rate and a value of 4.9 percent for the long-term risk-free interest rate as the benchmark risk-free interest rates in the equity risk premium analyses. These forecasts are constructed by using historical yield curve data to find the long-run average implied term premia on government securities, and combining these with recent yield curve data. Details of their calculation can be found in the Workpapers to Table No. MJV-9.

C. COST OF EQUITY METHODS

Q36. How do you estimate the cost of equity for your sample companies?

A36. Recall the definition of the cost of capital from the outset of my testimony: the expected rate of return in capital markets on alternative investments of equivalent risk. My cost of capital estimation procedures address three key points implied by the definition:

1. Since the cost of capital is an expected rate of return, it cannot be directly observed; it must be inferred from available evidence.

2. Since the cost of capital is determined in capital markets (e.g., the New York Stock Exchange), data from capital markets provide the best evidence from which to infer it.

3. Since the cost of capital depends on the return offered by alternative investments of equivalent risk, measures of the risks that matter in capital markets are part of the evidence that needs to be examined.

Q37. How does the above definition help in cost of capital estimation?

A37. The definition of the cost of capital recognizes a tradeoff between risk and expected return, plotted above in Figure 1, the security market line. Cost of capital estimation methods take one of two approaches: (1) they try to identify a comparable-risk sample of companies and to estimate the cost of capital directly; or (2) they establish the location of the security market line and estimate the relative risk of the security, which jointly determine the cost of capital. In terms of Figure 1, the first approach focuses directly on the vertical axis, while the second focuses both on the security's position on the horizontal axis and on the position of the security market line.

The first type of approach is more direct, but ignores the wealth of information available on securities not thought to be of precisely comparable risk. The "discounted cash flow" or "DCF" model is an example. The second type of approach, sometimes known as "equity risk premium approach," requires an extra step, but as a result can make use of information on all securities, not just a very limited subset. The Capital Asset Pricing Model ("CAPM") is an example. While both approaches can work equally well if conditions are right, one may be preferable to the other under a given set of circumstances. In particular, approaches that rely on the entire security market line (e.g., the risk positioning model) are less sensitive to deviations from the assumptions that underlie the model, all else equal. In this proceeding, I examine sample evidence from both the DCF and risk positioning models.

1. The Risk Positioning Approach

Q38. Please explain the risk positioning method.

A38. The risk positioning method estimates the cost of equity as the sum of a current interest rate and a company specific risk premium. It is therefore sometimes also known as the "risk premium" approach. This approach may sometimes be applied informally. For example, an analyst or Commission may check the spread between interest rates and what

is believed to be a reasonable estimate of the cost of capital at one time, and then apply that spread to changed interest rates to get a new estimate of the cost of capital at another time.

More formal applications of the risk positioning approach take full advantage of the security market line depicted in Figure 1: they use information on all securities to identify the security market line and derive the cost of capital for the individual security based on that security's relative risk. This reliance on the entire security market line makes the method less vulnerable to the kinds of problems that arise for the DCF method, which relies on one stock at a time. The risk positioning approach is widely used and underlies most of the current research published in academic journals on the nature, determinants and magnitude of the cost of capital.

Section I of Appendix C to this testimony provides more detail on the principles that underlie the risk positioning approach. Section II of Appendix C provides the details of the risk positioning approach empirical estimates I obtain.

Q39. How are the "more formal" applications of risk positioning approach implemented?

A39. The first step is to specify the current values of the parameters that determine the security market line. The second is to determine the security's or investment's relative risk. The third is to specify exactly how the parameters combine to produce the security market line, so the company's cost of capital can be calculated based on its relative risk. All of these elements and how they relate are usefully formulated in the framework of the CAPM.

a) The Capital Asset Pricing Model

Q40. Please start with the CAPM, by describing the model.

A40. As noted above, the modern models of capital market equilibrium express the cost of equity as the sum of a risk-free rate and a market risk premium. The CAPM is the longest-standing and most widely used of these theories. The CAPM states that the cost of capital for an investment, *s*, (e.g., a particular common stock) is given by the following equation:

$$k_s = r_f + \beta_s \times MRP \quad (2)$$

where k_s is the cost of capital for investment s; r_f is the risk-free rate, β_s is the beta risk measure for the investment s; and MRP is the market risk premium.

The CAPM relies on the empirical fact that investors price risky securities to offer a higher expected rate of return than safe securities do. It says that the security market line starts at the risk-free interest rate (that is the return on a zero-risk security, the y-axis intercept in Figure 1, equals the risk-free interest rate). It further says that the risk premium over the risk-free rate equals the product of beta and the risk premium on a value-weighted portfolio of all investments, which by definition has average risk.

b) The Empirical Capital Asset Pricing Model

Q41. What other equity risk premium model do you use?

A41. Empirical research has long shown that the CAPM tends to overstate the actual sensitivity of the cost of capital to beta: low-beta stocks tend to have higher risk premia than predicted by the CAPM and high-beta stocks tend to have lower risk premia than predicted. A number of variations on the original CAPM theory have been proposed to explain this finding, but this finding can also be used to estimate the cost of capital directly, using beta to measure relative risk without simultaneously relying on the CAPM.

The second model makes use of these empirical findings. It estimates the cost of capital with the equation, where α is the "alpha" adjustment of the risk-return line, a constant,

$$k_s = r_f + \alpha + \beta_s \times (MRP - \alpha) \quad (3)$$

and the other symbols are defined as above. I label this model the Empirical Capital Asset Pricing Model, or "ECAPM." The alpha adjustment has the effect of increasing the intercept but reducing the slope of the security market line in Figure 1, which results in a security market line that more closely matches the results of empirical tests.

Q42. Why is it appropriate for you to use the empirical CAPM?

A42. Although the CAPM is still the most widely used cost of capital estimation model, it has not been completely satisfactory as an empirical model; however, its short-comings are

directly addressed by the ECAPM. The ECAPM recognizes the consistent empirical observation that the CAPM underestimates (overestimates) the cost of capital for low (high) beta stocks. In other words, the ECAPM is based on the recognition that the actual slope of the risk-return tradeoff is flatter than predicted and the intercept higher based upon repeated empirical tests of the CAPM. The alpha parameter (α) in the ECAPM adjusts for this fact. The difference between the CAPM and the type of relationship identified in the empirical studies is depicted in Figure 2.

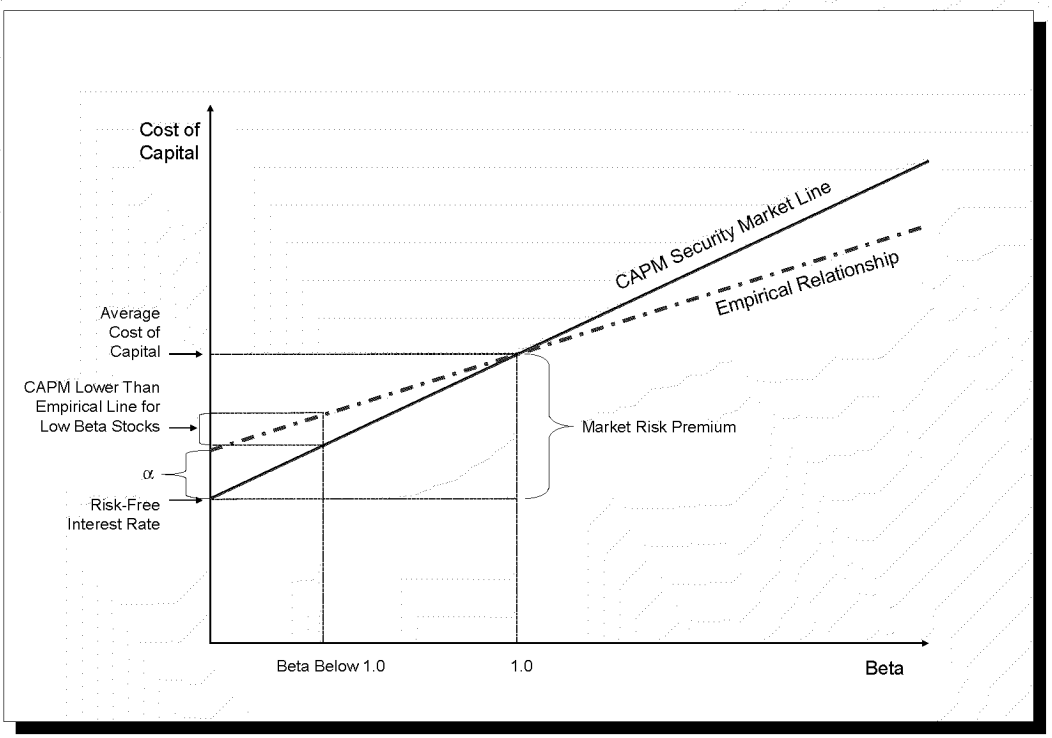

Figure 2: The Empirical Security Market Line

Research supports values for α of one to seven percent when using a short-term interest rate. I use baseline values of α of 2 percent for the short-term risk-free rate and 0.5 percent for the long-term risk-free rate. I also conduct sensitivity tests for different values of α. For the short-term risk-free rate I use values for α of 1, 2 and 3 percent. These α values are lower than would be justified by the magnitude of the correction revealed in the tests of the CAPM. For the long-term risk-free rate, the corresponding values for α are 0, 0.5 and 1.5 percent. The use of a long-term risk-free rate incorporates some of the desired effect of using the ECAPM. That is, the long-term risk-free rate version of the security market line has a higher intercept and a flatter slope than the short-

term risk-free version which has been extensively tested. Thus, I do not need to make the same degree of refinement when I use the long-term risk-free rate. Please see Table No. MJV-C1 in Appendix C for a summary of the empirical evidence on the size of the required adjustment necessary to better match the results of the empirical tests.

2. Discounted Cash Flow Method

Q43. Please describe the discounted cash flow approach.

A43. The DCF model takes the first approach to cost of capital estimation, i.e., to attempt to estimate the cost of capital in one step. The method assumes that the market price of a stock is equal to the present value of the dividends that its owners expect to receive. The method also assumes that this present value can be calculated by the standard formula for the present value of a cash flow stream:

$$P = \frac{D_1}{(1+k)} + \frac{D_2}{(1+k)^2} + \frac{D_3}{(1+k)^3} + \cdots + \frac{D_T}{(1+k)^T} \tag{4}$$

where "P" is the market price of the stock; "D_t" is the dividend cash flow expected at the end of period t (i.e., subscript period 1, 2, 3 or T in the equation); "k" is the cost of capital; and "T" is the last period in which a dividend cash flow is to be received. The formula just says that the stock price is equal to the sum of the expected future dividends, each discounted for the time and risk between now and the time the dividend is expected to be received.

Very often, when the DCF is applied in regulatory proceedings, very strong (i.e., unrealistic) assumptions are used that yield a simplification of the standard formula, which then can be rearranged to estimate the cost of capital. Specifically, it is assumed that investors expect a dividend stream that will grow *forever* at a steady rate, and if so, the market price of the stock will be given by a very simple formula,

$$P = \frac{D_1}{(k-g)} \tag{5}$$

where "D_1" is the dividend expected at the end of the first period, "g" is the perpetual growth rate, and "P" and "k" are the market price and the cost of capital, as before.

Equation (5) is a simplified version of equation (4) that can be solved to yield the well known "DCF formula" for the cost of capital:

$$\begin{aligned} k &= \frac{D_1}{P} + g \\ &= \frac{D_0 \times (1+g)}{P} + g \end{aligned} \tag{6}$$

where "D_0" is the current dividend, which investors expect to increase at rate g by the end of the next period, and the other symbols are defined as before. Equation (6) says that if equation (5) holds, the cost of capital equals the expected dividend yield plus the (perpetual) expected future (forever constant) growth rate of dividends. I refer to this as the simple DCF model. Of course, the "simple" model is simple because it relies on very strong (i.e., very unrealistic) assumptions.

Q44. Are there other versions of the DCF models besides the "simple" one?

A44. Yes. The constant growth rate DCF model requires that dividends and earnings grow at the same rate for companies that earn their cost of capital on average.[12] It is inconsistent with the theory on which the model is based to have different growth rates in earnings and dividends over the period when growth is assumed to be constant. If the growth in dividends and earnings were expected to vary over some number of years before settling down into a constant growth period, then it would be appropriate to estimate a multistage DCF model. In the multistage model, earnings and dividends can grow at different rates, but must grow at the same rate in the final, constant growth rate period. A difference between forecasted dividend and earnings rates therefore is a signal that the facts do not fit the assumptions of the simple DCF model.

[12] Why must the two growth rates be equal in a steady-growth DCF model? Think of earnings as divided between reinvestment, which funds future growth, and dividends. If dividends grow faster than earnings, there is less investment and slower growth each year. Sooner or later dividends will equal earnings. At that point, growth is zero because nothing is being reinvested (dividends are constant). If dividends grow slower than earnings, each year a bigger fraction of earnings are reinvested. That makes for ever faster growth. Both scenarios contradict the steady-growth assumption. So if you observe a company with different expectations for dividend and earnings growth, you know the company's stock price and its dividend growth forecast are inconsistent with the assumptions of the steady-growth DCF model.

So, I consider a variant of the DCF model that relies on slightly less strong assumptions in that it allows for varying dividend growth rates in the near term before assuming a perpetual growth rate beginning in year eleven. I use the forecast growth of GDP as the forecast of the long-term growth rate, i.e. year eleven on. This is a "multistage" variant of the DCF method. The DCF models are described in detail in Section I.A of Appendix D. (Section II of Appendix D provides the details of my empirical DCF results.)

Q45. What are the merits of the DCF approach?

A45. The DCF approach is conceptually sound if its assumptions are met, but can run into difficulty in practice because those assumptions are so strong[13], and hence so unlikely to correspond to reality. Dividends, earnings and prices are unlikely to grow at a constant rate literally forever. Two conditions are also well known to be necessary for the DCF approach to yield a reliable estimate of the cost of capital: the variant of the present value formula that is used must actually match the variations in investor expectations for the growth of dividends, and the growth rate(s) used in that formula must match current investor expectations. Less frequently noted conditions may also create problems (see Appendix D for details).

Q46. Is estimating the "right" dividend growth rate the most difficult part for the implementation of the DCF approach?

A46. Yes. Finding the right growth rate(s) is the usual "hard part" of a DCF application. The original approach to estimation of g relied on average historical growth rates in observable variables, such as dividends or earnings, or on the "sustainable growth" approach, which estimates g as the average book rate of return times the fraction of earnings retained within the firm. But it is highly unlikely that these historical averages over periods with widely varying rates of inflation and costs of capital will equal current growth rate expectations. As discussed above, this is particularly true for the electric industry at present because the ultimate structure of the industry is uncertain. The movement toward restructuring has stalled and, in some locations, a reversal of the process is being considered. In addition, there is uncertainty associated with the possible

[13] In this context "strong" means that the assumption is unlikely to match reality and that it also has a substantial impact on the model's results.

imposition new environmental regulations. These are not a description of the stable conditions necessary for the reliable implementation of the DCF model.

IV. THE OHIO EDUs' COST OF CAPITAL

A. THE OHIO EDUs' OPERATIONS AND RISKS

Q47. Please describe the operating characteristics of the Ohio EDUs.

A47. As of January 1, 2001, Ohio businesses and residential customers have had the opportunity to choose their energy supplier. The Ohio EDUs also serve as providers of last resort ("POLR") which means that any customer not selecting an alternative supplier must be supplied power by the electric distribution company. Because the competitive markets have not evolved as quickly as was envisioned, the PUCO approved Rate Stabilization Plans ("RSP") for the Ohio electric utilities - the Ohio EDUs provide POLR service under these RSPs.

B. SAMPLE SELECTION

Q48. How did you select your sample of electric utilities?

A48. The goal was to create a sample of companies whose primary business is as a regulated electric utility with business risk generally similar to that of the Ohio EDUs. To construct this sample, I formed a universe of 61 companies by combining the electric companies under East, Central and West categories listed in *Value Line*. From this group companies were first eliminated if their operating regions were outside of the continental USA or if they were primarily engaged in generation and/or transmission. I then applied my standard selection criteria outlined earlier to remove companies without sufficient data to estimate their cost of capital, companies showing signs of financial distress (i.e. less than an investment grade credit rating from S&P), with large recent merger and acquisition ("M&A") activity, recent dividend cuts, companies with a small market capitalization, and companies whose share of regulated assets was estimated to be less than 50 percent.

Specifically, I required the sample companies to have an investment grade credit rating (i.e., BBB- or above), have had no dividend cuts in the past five years, have revenues of at least $300 million and have five years of historical data in Bloomberg. I also required that the companies have engaged in no major merger or acquisition during the last five years. A total of nine companies met all of these requirements: Cleco Corp, Consolidated Edison, Empire District Electric, Entergy Corp, MGE Energy, NSTAR, Pinnacle West Capital Corp, PPL Corp, and Southern Co. Details on the sample selection process are in Appendix B. Characteristics of the sample companies are outlined in Table 1 below.

Table 1: Benchmark Electric Sample

Company	Revenue (2006) ($MM) [1]	Regulated Electric Assets [2]	Market Cap. (2006) ($MM) [3]	S&P Bond Rating (2007) [4]	Beta [5]	Long-Term Growth Estimate [6]
Cleco Corp	1,001	R	1,463	BBB	1.30	12.3%
Consolidated Edison Inc	12,137	R	12,362	A	0.75	3.5%
Empire District Electric Co	413	R	750	BBB-	0.80	4.7%
Entergy Corp	10,932	R	18,786	BBB	0.85	8.2%
MGE Energy Inc	508	MR	764	AA-	0.75	7.0%
NSTAR	3,578	R	3,689	A+	0.80	6.1%
Pinnacle West Capital Corp	3,402	R	5,061	BBB-	1.00	2.9%
PPL Corp	6,899	MR	13,855	BBB	0.95	13.2%
Southern Co	14,356	R	27,609	A	0.70	4.9%
FirstEnergy Corp.	*11,501*	*MR*	*19,375*	*BBB*	*0.85*	*5.7%*

[2] R – Regulated (> 80 percent of total assets are regulated).
MR – Mostly Regulated (50 to 80 percent of total assets regulated).
Source: Edison Electric Institute 2006 Financial Review.

[3] See Table MJV-3 for calculations. First Energy Corp.'s number is based on the same calculation as for the other companies and uses data from Bloomberg as of April 9, 2007.

[4] Bloomberg as of April 9, 2007.

[5] Value Line Investment Survey

[6] See Table MJV-5. First Energy Corp.'s number is based on a BEst long term growth forecast of 5.8% (4 estimates, Bloomberg as of April 9, 2007) and an implied annualized long-term growth rate from Value Line of 5.3%.

1. Characteristics of the Sample

Q49. Table 1 lists the characteristics of the sample. Does the sample exactly match the risk characteristics of the Ohio EDUs?

A49. No, the sample does not perfectly match the risk characteristics of the Ohio EDUs. In general, there is no perfect sample. There is always a trade-off between sample size and

imposing sample selection criteria designed to remove companies from the sample that may potentially bias the estimated costs of capital. In this case, I believe that this sample is the best currently available given the ongoing changes in the electric industry.

2. Comparison of the Risk of the Sample to Risk of the Ohio EDUs

Q50. Please summarize the general risk characteristics of the companies in the sample and those of the Ohio EDUs.

A50. The sample consists of six integrated utilities and three companies with a POLR obligation operating in states that have already transitioned to market based rates. A summary of their risk characteristics is provided in Table 2 below.

Table 2: Risk Characteristics of Sample Companies

	States Served	Electric Subsidiaries	POLR [1]	Rate Cap for POLR Utilities [2]	Fuel Cost Adjustment [3]	S&P Business Profile [4]	S&P Business Class [5]
States with Full Restructuring							
Consolidated Edison Inc	NY	Con Edison of New York	Yes	No	Yes	2	TD
	NY	Orange and Rockland	Yes	No	Yes		
	NJ		Yes	No	No		
	PA		Yes	No	No		
NSTAR	MA	NSTAR	Yes	No	Yes	1	TD
PPL Corp	PA	PPL Electric Utilities Co	Yes	Yes [until 2009]	No	7	D
FirstEnergy Corp	*OH*	*Ohio Edison / Cleveland Electric Illuminating / Toledo Edison / ATSI*	*Yes*	*YES However, settlements allow some increase.*	*Yes*	*6*	*D*

Company 10-K's, 2006.

Q51. How does the risk of the sample compare to the risk of the Ohio EDUs?

A51. In general, the sample appears to be less risky than the Ohio EDUs. Only three of the sample companies appear to have a POLR obligation, and they are in states that have already moved to market based rates. As a result, they face a different kind of regulatory uncertainty than the Ohio EDUs currently do – an uncertainty that may be an ongoing feature of market rates given the volatility of fuel prices. Consumers are averse to highly volatile energy prices, and regulatory authorities may be reluctant to pass through to consumers market prices that are too variable. The Ohio EDUs, on the other hand, face uncertainty regarding how the final transition to market based prices will be implemented. The Ohio EDUs are currently operating in a situation where they provide a POLR service with a rate cap although some costs may be deferred and recovered over a 25-year period, but they must procure electricity at market prices. As such, should the costs of procuring electricity rise in the post RSP period, the Ohio EDUs may potentially suffer losses if they are not able to fully recover their costs. It is not clear whether such losses will be deemed recoverable by the future Commissions in place when Ohio finalizes its transition to market rates in 2009. Although both types of POLR companies face their own associated risks, the risk faced by those in transition should be considered greater.

Q52. How do the general risks of the integrated utilities in the sample compare to the risks posed by the POLR obligations faced by the Ohio EDUs?

A52. The risks faced by the integrated utilities are generally less than those faced by electric distribution companies with a POLR obligation. The biggest risk difference between the two is that integrated utilities own generation capacity to meet the power needs of their customers. Although integrated electric utilities are still exposed to changes in fuel prices as well as the construction and operating risk of owning generation, they have a natural hedge against volatile energy prices through their ownership of generation assets. POLR companies, on the other hand, are potentially exposed to changes in market prices not related to the volatility of fuel prices because they must purchase power at market prices. The risk for POLR companies is directly related to the assurance of the full recovery of the costs of providing the POLR service. The less assured the recovery, the greater the risk for the company.

C. COST OF CAPITAL ESTIMATES

Q53. Please summarize the results of the risk positioning and DCF methodologies in estimating the average cost of capital for the benchmark sample, and the implications for the Ohio EDUs' cost of equity?

A53. Table 3 summarizes the sample average ATWACCs derived from the risk positioning and DCF models, along with the implied cost of equity for the Ohio EDUs at their filed regulatory capital structure with 49 percent equity.

Table 3: Cost of Equity Results

Regulatory Capital Structure:	*49.0% Equity / 51.0% Debt*							*2008 Tax Rate:*	*37%*
	METHODS								
	RISK POSITIONING (using Long-Term Risk-Free Rate)			RISK POSITIONING (using Short-Term Risk-Free Rate)				DCF

Short-Term: Risk Free Rate Estimate: 3.8%; Estimated MRP: 8.0%

Long-Term: Risk Free Rate Estimate: 4.9%; Estimated MRP: 6.5%

Multi-Stage DCF Parameter: GDP Growth Estimate: 5.1%

Sources and Notes:

* For the US Electric Sample, Risk Positioning data from Table No. MJV-12 and DCF data from Table No. MJV-8.

[1] The sample consists of Cleco Corp., Consolidated Edison, Empire District Electric Co., Entergy, MGE Energy, NSTAR, Pinnacle West Capital Corp., PPL Corp., and Southern Co.

[2] See Appendix C and D for details on Risk Positioning and DCF parameters used in estimates.

Q54. How did you determine a representative tax rate to use in your cost of capital estimation?

A54. Each of the Ohio EDUs has a slightly different estimated marginal income tax rate for 2008. Specifically, FirstEnergy estimates Ohio Edison's 2008 rate as 37.2485 percent, Toledo Edison's as 37.1326 percent, and Cleveland Electric Illuminating's as 37.1476 percent. To be conservative, my calculation of the after-tax cost of capital is based on the lowest of these, which is 37.1326 percent. It is conservative in the sense that this approach results in the lowest cost of equity recommendation for the Ohio EDUs after adjusting for differences in financial risk between the sample and the Ohio EDUs.

Q55. How are the cost of equity estimates derived from the risk positioning approach for the benchmark sample?

A55. I derive two sets of risk-positioning estimates, one using long-term forecasts of the risk-free rate and market risk premium, and one using short-term forecasts. My long-term interest rate forecast is 4.9 percent and the corresponding estimated market risk premium is 6.5 percent. When using the short-term risk-free rate of 3.8 percent, the estimated MRP is 8.0 percent. Details on the derivation of these forecasts can be found in Appendix C.

For each estimated risk-free rate, the two risk positioning models (CAPM and ECAPM) are estimated utilizing the different values of the ECAPM parameter (0.5% and 1.5% for the long-term model and 1%, 2%, and 3% for the short-term model). I therefore obtain three long-term and four short-term estimates of each sample company's cost of equity. The results using the long-term risk-free rate are displayed in Table MJV-10, Panel A, and the results using the short-term risk-free rate are displayed in Table MJV-10, Panel B. Next, the cost of equity estimates are combined with each company's estimated cost of debt and preferred equity to calculate the company's ATWACC using each company's market value capital structure. These calculations and the resulting sample average ATWACCs are presented in Table No. MJV-11. Panels A-C rely on the cost of equity estimates from the long-term version of the model, while Panels D-G utilize the estimates from the short-term version of the model. The sample average ATWACCs and costs of equity at the Ohio EDUs' 49 percent equity capital structure for each risk positioning cost of equity estimate are displayed in Table No. MJV-12. These results are summarized in Table 3 above.

Q56. What are the DCF estimates for the benchmark sample?

A56. For each sample company, cost-of-equity estimates are calculated for the two versions of the DCF method, the simple DCF model and multistage DCF model. The DCF estimates for each company are displayed in Table No. MJV-6, Panel A (simple DCF) and Panel B (multistage DCF). The sample average ATWACC for each method is calculated in Table No. MJV-7 and the resulting sample average ATWACC is used in Table No. MJV-8 to derive returns on equity at Ohio EDUs' 49 percent equity capital structure. These results

are shown in Table 3 above, along with the sample average ATWACC numbers. Table 3 shows the estimated costs of equity to be 13.4 percent (simple DCF model) and 11.2 percent (multistage DCF model). The estimates from the simple DCF exceed the estimates from both the long-term and short-term risk positioning models, but the estimates from the multistage DCF model are lower than all of the risk positioning estimates (see Table 3: Cost of Equity Results above).

V. CONCLUSIONS

Q57. What are your conclusions from the DCF model regarding the cost of equity at the Ohio EDUs' 49 percent equity ratio?

A57. The estimated costs of equity from the simple DCF model are substantially higher than the estimates from the multistage model, and higher than any of the risk positioning model estimates. The simple DCF model relies on company-specific growth rate forecasts, but those forecasts vary significantly among the companies in the sample, with Cleco Corp., Empire Electric, and Entergy displaying significantly higher estimates as noted earlier. The variation in growth rate forecasts suggests that the simple DCF estimates are unreliable because the long-run growth rate forecast drives the results, and there are no objective data on the long-run growth rate investors truly expect, nor on when the industry is expected to settle down into some sort of stable-growth equilibrium. The more reliable multistage DCF estimate, after adjustment for financial risk, is 11.2 percent which is about 200 basis points lower than the simple DCF estimate and about 60 and 90 basis points lower than the long-term risk positioning estimates. Although I do not put much weight upon the DCF model results in my recommended cost of equity for the Ohio EDUs, I believe that DCF cost capital estimates provide a useful check on the risk positioning results.

Q58. Do you have any comments regarding the results of the risk positioning models?

A58. The risk positioning results are summarized above in Table 3. At this time, the estimated costs of equity displayed in Table No. MJV-12 for the long-term version of the model are lower than for the short-term version of the model. Of those results, the CAPM values deserve the least weight, because this method does not adjust for the empirical finding

that the cost of capital is less sensitive to beta than predicted by the CAPM (which my testimony considers by using the ECAPM). Conversely, the ECAPM numbers deserve the most weight, because this method adjusts for the empirical findings. The cost of equity estimates using the long-term risk free rate and adjusted for a capital structure with a 49 percent equity ratio range from 11.8 to 12.1 percent, while for the short-run estimates they range from 12.1 to 12.5 percent.

The estimates based upon the short-term risk-free rate are about 35 basis points higher on average than the estimates using the long-term risk-free rate. This is a result of the fact that the yield curve is currently flat or slightly inverted, i.e., the yield on short-term Treasury bills exceeds the yield on long-term Treasury bonds. Panel A of Table No. MJV-9 shows that 30-day Treasury bills are currently yielding an average of 5.16 percent compared to only 4.90 percent for long-term Treasury bonds. This relationship between the yield on short-term and long-term Treasury securities is unusual. Yields on long-term Treasury bonds have averaged about 150 basis points more than the yields on 30-day Treasury bills over the last 80 years. (See Workpaper #1, Panel B to Table No. MJV-9) The yield on short-term Treasury bills reflects the efforts by the Federal Reserve ("Fed") to prevent the rate of inflation from increasing any further. If the Fed believes that inflation is not yet contained, short-term rates are likely to increase further. On the other hand, if inflation is judged to be under control, short-term rates may decline as fears of recession replace those of inflation. Because of this uncertainty, I believe that the estimates using the long-term risk-free rate are more reliable at this time.

Q59. Given the results of the two models, what is your conclusion regarding the cost of equity for The Ohio EDUs?

A59. Focusing on the middle values in Table 3 for the results from the long-term risk positioning model (ECAPM with $\alpha = 0.5$), the average ATWACC for the full sample is 7.8 percent, with a corresponding costs of equity estimates of 11.9 percent. The results for the more reliable multistage version of the DCF model are an average ATWACC of 7.5 percent, with a corresponding cost of equity of 11.2 percent. Based upon considering all of the evidence from both models, the best point estimate for the cost of equity for the Ohio EDUs is 11¾ percent. This result is about ½ percent lower than the average risk

positioning results from the short-term model estimates. It is also about ½ percent higher than the multistage DCF estimates. However, it is more correct to say that the estimates from the sample provide a range of values from a low of 11¼ percent to a high of 12¼ percent. As previously noted, in estimating the cost of equity I round to the nearest ¼ percent (25 basis points) because I do not believe that cost of capital estimates can be made more precisely than that.

Q60. Does this conclude your testimony?

A60. Yes

APPENDIX A

RESUMÉ

MICHAEL J. VILBERT **PRINCIPAL**

Michael Vilbert is an expert in cost of capital, financial planning and valuation who has advised clients on these matters in the context of a wide variety of investment and regulatory decisions. He received his Ph.D. in Financial Economics from the Wharton School of the University of Pennsylvania, an MBA from the University of Utah, an M.S. from the Fletcher School of Law and Diplomacy, Tufts University, and a B.S. degree from the United States Air Force Academy. He joined The Brattle Group in 1994 after a career as an Air Force officer, where he served as a fighter pilot, intelligence officer, and professor of finance at the Air Force Academy.

REPRESENTATIVE CONSULTING EXPERIENCE

- In a securities fraud case, Dr. Vilbert designed and created a model to value the private placement stock of a drug store chain as if there had been full disclosure of the actual financial condition of the firm. He analyzed key financial data and security analyst's reports regarding the future of the industry in order to recreate pro forma balance sheet and income statements under a variety of scenarios designed to establish the value of the firm.

- For pharmaceutical companies rebutting price-fixing claims in antitrust litigation, Dr. Vilbert was a member of a team which prepared a comprehensive analysis of industry profitability. The analysis replicated, tested and critiqued the major recent analyses of drug costs, risks and returns. The analyses helped develop expert witness testimony to rebut allegations of excess profits.

- For an independent electric power producer, Dr. Vilbert created a model that analyzed the reasonableness of rates and costs filed by a natural gas pipeline. The model not only duplicated the pipeline's rates, but it also allowed simulation of a variety of "what if" scenarios associated with cost recovery under alternative time patterns and joint cost allocations. Results of the analysis were adopted by the intervenor group for negotiation with the pipeline.

- For the CFO of an electric utility, Dr. Vilbert developed the valuation model used to support a stranded cost estimation filing. The case involved a conflict between two utilities over the responsibility for out-of-market costs associated with a power purchase contract between them. In addition, he advised and analyzed cost recovery mechanisms

that would allow full recovery of the stranded costs while providing a rate reduction for the company's rate payers.

- Dr. Vilbert has testified as well as assisted in the preparation of testimony and the development of estimation models in numerous cost of capital cases for natural gas pipeline, water utility and electric utility clients before the Federal Energy Regulatory Commission ("FERC") and state regulatory commissions. These have spanned standard estimation techniques (e.g., Discounted Cash Flow and Risk Positioning models). He has also developed and applied more advanced models specific to the industries or lines of business in question, e.g., based on the structure and risk characteristics of cash flows, or based on multi-factor models that better characterize regulated industries.

- Dr. Vilbert has valued several large, residual oil-fired generating stations to evaluate the possible conversion to natural gas or other fuels. In these analyses, the expected pre- and post-conversion station values were computed using a range of market electricity and fuel cost conditions.

- For a major western electric utility, Dr. Vilbert helped prepare testimony that analyzed the prudence of QF contract enforcement. The testimony demonstrated that the utility had not been compensated in its allowed cost of capital for major disallowances stemming from QF contract management.

- Dr. Vilbert analyzed the economic need for a major natural gas pipeline expansion to the Midwest. This involved evaluating forecasts of natural gas use in various regions of the United States and the effect of additional supplies on the pattern of natural gas pipeline use. The analysis was used to justify the expansion before the FERC and the National Energy Board of Canada.

- For a Public Utility Commission in the Northeast, Dr. Vilbert analyzed the auction of an electric utilities purchase power agreements to determine whether the outcome of the auction was in the ratepayers' interest. The work involved the analysis of the auction procedures as well as the benefits to ratepayers of transferring risk of the PPA payments to the buyer.

- Dr. Vilbert led a team tasked to determine whether bridge tolls were "just and reasonable" for a non-profit port authority. Determination of the cost of service for the authority required estimation of the value of the authority's assets using the trended original cost methodology as well as evaluation of the operations and maintenance budgets. Investment costs, bridge traffic information and inflation indices covering a 75 year period were utilized to estimate the value of four bridges and a passenger transit line valued in excess of $1 billion.

- Dr. Vilbert helped a recently privatized railroad in Brazil develop an estimate of its revenue requirements, including a determination of the railroad's cost of capital. He also helped evaluate alternative rate structures designed to provide economic incentives to shippers as well as to the railroad for improved service. This involved the explanation

and analysis of the contribution margin of numerous shipper products, improved cost analysis and evaluation of bottlenecks in the system.

- For a utility in the Southeast, Dr. Vilbert quantified the company's stranded costs under several legislative electric restructuring scenarios. This involved the evaluation of all of the company's fossil and nuclear generating units, its contracts with Qualifying Facilities and the prudence of those QF contracts. He provided analysis concerning the impact of securitizing the company's stranded costs as a means of reducing the cost to the rate payers and several alternative designs for recovering stranded costs.

- For a recently privatized electric utility in Australia, Dr. Vilbert evaluated the proposed regulatory scheme of the Australian Competition and Consumer Commission for the company's electric transmission system. The evaluation highlighted the elements of the proposed regulation which would impose uncompensated asymmetric risks on the company and the need to either eliminate the asymmetry in risk or provide additional compensation so that the company could expect to earn its cost of capital.

- For an electric utility in the Southwest, Dr. Vilbert helped design and create a model to estimate the stranded costs of the company's portfolio of Qualifying Facilities and Power Purchase contracts. This exercise was complicated by the many variations in the provisions of the contracts that required modeling in order to capture the effect of changes in either the performance of the plants or in the estimated market price of electricity.

- Dr. Vilbert helped prepare the testimony responding to a FERC request for further comments on the appropriate return on equity for electric transmission facilities. In addition, Dr. Vilbert was a member of the team that made a presentation to the FERC staff on the expected risks of the unbundled electric transmission line of business.

- Dr. Vilbert and Mr. Frank C. Graves, also of The Brattle Group, prepared testimony evaluating an innovative Canadian stranded cost recovery procedure involving the auctioning of the output of the province's electric generation plants instead of the plants themselves. The evaluation required the analysis of the terms and conditions of the long-term contracts specifying the revenue requirements of the plants for their entire forecasted remaining economic life and required an estimate of the cost of capital for the plant owners under this new stranded cost recovery concept.

- Dr. Vilbert served as the neutral arbitrator for the valuation of a petroleum products tanker. The valuation required analysis of the Jones Act tanker market and the supply and demand balance of the available U.S. constructed tanker fleet.

TESTIMONY

Direct and rebuttal testimony before the Alberta Energy and Utilities Board on behalf of TransAlta Utilities Corporation in the matter of an application for approval of its 1999 and 2000 generation tariff, transmission tariff, and distribution revenue requirement, October 1998.

Direct testimony before the Federal Energy Regulatory Commission on behalf of Central Maine Power in Docket No. ER00-982-000, December 1999.

Direct testimony before the Alberta Energy and Utilities Board on behalf of TransAlta Utilities Corporation for approval of its 2001 transmission tariff, May 2000.

Direct testimony before the Federal Energy Regulatory Commission on behalf of Mississippi River Transmission Corporation in Docket No. RP01-292-000, March 2001.

Written evidence, rebuttal, reply and further reply before the National Energy Board in the matter of an application by TransCanada PipeLines Limited for orders pursuant to Part I and Part IV of the *National Energy Board Act*, Order AO-1-RH-4-2001, May 2001, Nov. 2001, Feb. 2002.

Written evidence before the Public Utility Board on behalf of Newfoundland & Labrador Hydro - Rate Hearings, October 2001.

Direct testimony (with Bill Lindsay) before the Federal Energy Regulatory Commission on behalf of DTE East China, LLC in Docket No. ER02-1599-000, April 2002.

Direct and rebuttal reports before the Arbitration Panel in the arbitration of stranded costs for the City of Casselberry, FL, Case No. 00-CA-1107-16-L, July 2002.

Direct reports before the Arbitration Board for Petroleum products trade in the Arbitration of the Military Sealift Command vs. Household Commercial Financial Services, fair value of sale of the Darnell, October 2002.

Direct testimony and hearing before the Arbitration Panel in the arbitration of stranded costs for the City of Winter Park, FL, In the Circuit Court of the Ninth Judicial Circuit in and for Orange County, FL, Case No. C1-01-4558-39, December 2002.

Direct testimony before the Federal Energy Regulatory Commission on behalf of Florida Power Corporation, dba Progress Energy Florida, Inc. in Docket No. SC03-___-000, March 2003.

Direct report before the Arbitration Panel in the arbitration of stranded costs for the Town of Belleair, FL, Case No. 000-6487-C1-007, April 2003.

Direct and rebuttal reports before the Alberta Energy and Utilities Board in the matter of the Alberta Energy and Utilities Board Act, R.S.A. 2000, c. A-17, and the Regulations under it; in the matter of the Gas Utilities Act, R.S.A. 2000, c. G-5, and the Regulations under it; in the matter of the Public utilities Board Act, R.S.A. 2000, c. P-45, as amended, and the Regulations

under it; and in the matter of Alberta Energy and Utilities Generic Cost of Capital Hearing, Proceeding No. 1271597, July 2003, November 2003.

Written evidence before the National Energy Board in the matter of the National Energy Board Act, R.S.C. 1985, c. N–7, as amended, (Act) and the Regulations made under it; and in the matter of an application by TransCanada PipeLines Limited for orders pursuant to Part IV of the *National Energy Board Act*, for approval of Mainline Tolls for 2004, RH-2-2004, January 2004.

Direct and rebuttal testimony before the Public Service Commission of West Virginia, on Cost of Capital for West Virginia-American Water Company, Case No 04-0373-W-42T, May 2004.

Direct and rebuttal testimony before the Federal Energy Regulatory Commission, on Energy Allocation of Debt Cost for Incremental Shipping Rates for Edison Mission Energy, Docket No. RP04-274-000, December 2004 and March 2005.

Direct testimony before the Arizona Corporation Commission, Cost of Capital for Paradise Valley Water Company, a subsidiary of Arizona-American Water Company, Docket No. WS-01303A-05, May 2005.

Written evidence before the Ontario Energy Board, Cost of Capital for Union Gas Limited, Inc., Docket No. EB-2005-0520, January 2006.

Direct and rebuttal testimony before the Pennsylvania Public Utility Commission, Return on Equity for Metropolitan Edison Company, Docket No. R-00061366 and Pennsylvania Electric Company, Docket No. R-00061367, April 2006 and August 2006.

Expert report in the United States Tax Court, Docket No. 21309-05, 34th Street Partners, DH Petersburg Investment, LLC and Mid-Atlantic Finance, Partners Other than the Tax Matters Partner, Petitioner, v. Commissioner of Internal Revenue, Respondent, July 28, 2006.

Direct and supplemental testimony before the Federal Energy Regulatory Commission, Docket No. ER06-427-003, on behalf of Mystic Development, LLC on the Cost of Capital for Mystic 8 and 9 Generating Plants Operating Under an Reliability Must Run Contract, August 2006 and September 2006.

Direct testimony before the Federal Energy Regulatory Commission, Docket No. ER07-46-000, on behalf of Northwestern Corporation on the Cost of Capital for Transmission Assets, October 2006.

Direct and rebuttal testimony before the Tennessee Regulatory Authority, Case No. 06-00290, on behalf of Tennessee American Water Company, on the Cost of Capital, November, 2006 and April 2007.

Direct testimony before the Public Service Commission of Wisconsin, Docket No. _____, on behalf of Wisconsin Energy Corporation, on the Cost of Capital for Wisconsin Electric Power Company and Wisconsin Gas LLC, May 2007.

Rebuttal testimony before the California Public Utilities Commission, Docket No. A. 07-01-036-39, on behalf of California-American Water Company, on the Cost of Capital, May 2007.

APPENDIX B

SELECTING THE BENCHMARK SAMPLE AND USE OF MARKET VALUES

I. SAMPLE SELECTION AND THE SAMPLE'S CHARACTERISTICS B-1

II. MARKET VALUE CAPITAL STRUCTURE, COSTS OF DEBT & COSTS OF PREFERRED EQUITY B-3

I. SAMPLE SELECTION AND THE SAMPLE'S CHARACTERISTICS

Q1. How did you select your sample of electric utilities?

A1. The goal was to create a sample of companies whose primary business is as a regulated electric utility with business risk generally similar to that of the Ohio EDUs. To construct this sample, I formed a universe from the 61 companies found in *Value Line*'s East, Central and West districts of electric companies. From this group, companies were first eliminated if their operating regions were outside of the continental USA or if they were primarily or solely engaged in generation and/or transmission. I then applied my standard selection criteria outlined earlier in Section III. A of my direct testimony to remove companies that have characteristics that may bias the cost of capital estimates.

Specifically, I eliminated all companies whose S&P bond rating as reported by Bloomberg was not investment grade, i.e., less than BBB-. To guard against measurement bias caused by "thin trading," I also restricted the sample to companies with total operating revenues greater than $300 million (USD) in 2006 as reported by Bloomberg,[1] and which had no significant mergers and acquisition activity over the past five years. The screen for merger activity was primarily done according to M&A data provided by Bloomberg and through a search of company web pages. To further ensure comparability to the Ohio EDUs' operations, companies whose share of regulated assets were not estimated to be at least "Mostly Regulated", as classified by the Edison Electric Institute ("EEI"), were removed.[2]

Finally, I required that the companies have historical data available from Bloomberg for the most recent five years and had no dividend cuts or restatement of financial statements in the past five years, since the latter can be signs of financial distress.

---

[1] Data was reviewed during the first week of April 2007.

[2] EEI has three classifications for electric utilities based upon the percentage of total assets that are regulated. The categories are Regulated (> 80% regulated), Mostly Regulated (50-80% regulated) and Diversified (< 50% regulated). See *EEI 2006 Financial Review*, p. 24.

A total of nine companies met all of these requirements: Cleco Corp, Consolidated Edison, Empire District Electric, Entergy Corp, MGE Energy, NSTAR, Pinnacle West Capital Corp, PPL Corp, and Southern Co.

Q2. Please elaborate on how companies were eliminated to arrive at your sample?

A2. Eleven companies were excluded due to less than investment grade credit rating. Two were excluded for less than $300 million in 2006 revenues – Green Mountain Power and ITC Holding Corp. (ITC also had less than five years of data). Of the remaining companies, 19 had excessive merger and acquisition activity ("M&A") and/or dividend cuts over the past five years. A further nine were also eliminated for dividend cuts or because they essentially own only generation or transmission assets.

Q3. How does the risk of the sample compare to the risk of the Ohio EDUs?

A3. In general, the sample appears to be of similar risk to the Ohio EDUs. Six of the nine companies are integrated utilities and all but Empire Electric have some form of fuel-cost adjustment mechanisms covering the bulk of their operations. Three sample companies have a provider of last resort ("POLR") obligation, and they are in states that have moved to market based rates. As a result, they face regulatory uncertainty in this respect as do the Ohio EDUs. All sample companies face uncertainty associated with the recent volatility of fuel prices. Since consumers have demonstrated an aversion to highly volatile energy prices, regulatory authorities may be reluctant to allow full recovery of energy prices that are too variable.

Depending upon the recovery mechanism for the costs of providing POLR service, the risks faced by electric distribution companies with a POLR obligation may be greater than or less than those of an integrated utility. The biggest risk difference between the two is that integrated utilities own the generation capacity to meet the power needs of their customers whereas electric distribution companies must contract for all or nearly all of the energy and capacity need to supply their customers. Although integrated utilities are still exposed to changes in fuel prices as well as the construction and operating risk of owning generation, they have a natural hedge against volatile energy prices through their ownership of generation assets. POLR companies, on the other hand, are potentially

exposed to changes in market prices not related to the volatility of fuel prices, because they must purchase power at market prices. The risk may be quite high if the full recovery of all of the costs of providing the POLR service is not assured.

II. MARKET VALUE CAPITAL STRUCTURE, COSTS OF DEBT & COSTS OF PREFERRED EQUITY

Q4. What capital structure information do you require?

A4. For reasons discussed in my direct testimony and explained in detail in Appendix E, explicit evaluation of the market-value capital structures of the sample companies versus the capital structure used for rate making is vital for a correct interpretation of the market evidence. This requires estimates of the market values of common and preferred equity and debt, and the current market costs of preferred equity and debt.

Q5. How do you calculate the market-value capital structures of the sample companies?

A5. I estimate the capital structure for each company by estimating the market values of common equity, preferred equity and debt from publicly available data. The calculations are in Panels A to I of Table No. MJV-3.

The market value of equity is straightforward: the price per share times the number of shares outstanding. The market value of preferred is set equal to its book value because the portion of the capital structure financed with preferred equity is generally small. The market value of debt is estimated at the book value of debt reported by Bloomberg plus or minus the difference in the estimated fair (market) value and book value of long-term debt as reported in the companies' 10-Ks or annual reports.[3]

For purposes of assessing financial risk to common shareholders, I add an adjustment for short-term debt to the debt portion of the capital structure. This adjustment is used only for those companies whose short-term (current) liabilities exceed their short-term (current) assets. I add an amount equal to the minimum of the difference between short-

[3] See Panels A through I in Table No. MJV-3 for details. The adjustment relies on the difference between the companies' self-reported fair value of long-term debt and the carrying value of the same line items. This information was obtained from the sample companies' annual reports.

term liabilities and short-term assets or the amount of short-term debt. The reason for this adjustment is to recognize that when current liabilities exceed current assets, a portion of the companies long-term assets are being financed, in effect, by short-term debt.

The market value capital structure is calculated to be consistent with the time period over which the cost of capital is estimated for the sample. The capital structure is determined over the historical period over which the relevant risk positioning parameters were determined and as of the date analysts provide forward looking growth forecasts. Therefore, Table No. MJV-3 reports the market value capital structure at year end for the years ending 2002 - 2006. The output of these tables is the market equity-to-value, debt-to-value, and preferred equity-to-value ratios. The overall cost of capital calculation for the risk positioning estimates samples rely on the average of the market value capital structure computed for the years 2002 through 2006 as shown in Table No. MJV-4. The results in columns [1]-[3] are used in the DCF model calculations, while columns [4]-[6] are for the risk positioning models.

Q6. How do you estimate the current market cost of preferred equity?

A6. For companies with preferred equity, the cost of preferred equity for each company was set equal to the yield on an index of preferred stock as reported in the Mergent Bond Record corresponding to the S&P rating of that company's debt. The yields from Mergent were as of March 2007. In general, the average amount of preferred equity in the sample companies' capital structures is very small and frequently zero. No company has more than two percent preferred on average.[4]

Q7. How do you estimate the current market cost of debt?

A7. The market cost of debt for each company in the DCF analysis is the current yield reported by Bloomberg for a public utility company bond corresponding to the sample company's current debt rating as classified by S&P. The risk positioning analysis, on the other hand, uses the current yield of a utility bond that corresponds to the five-year average debt rating of each company so as to match consistently the horizon of

[4] The Ohio EDUs have no preferred securities in their regulatory capital structure.

information used by *Value Line* to estimate company betas. The current S&P debt ratings were obtained from Bloomberg.

Bloomberg reports that as of March 27, 2007, the average yield on A-rated Public Utility bonds was 5.85 percent, and 6.11 percent on average for BBB-rated Public Utility bonds.[5] (See Panel C of Workpaper #1 to Table No. MJV-11 for the yields on utility bonds and preferred stock by credit rating.) As discussed in the Direct Testimony, calculation of the after-tax cost of debt uses the lowest marginal tax rate provided by the companies of 37.1326 percent.

[5] All companies in the sample are either BBB, AA, or A. The yield on AA-rated utility bonds is calculated as the yield on A-rated utility bonds minus ½ times the spread between the yield on BBB and A rated utility bonds.

A. RISK-FREE INTEREST RATE FORECAST C-15

B. BETAS AND THE MARKET RISK PREMIUM C-16

1. Beta Estimation Procedures C-16

2. Market Risk Premium Estimation C-16

C. COST OF CAPITAL ESTIMATES C-16

Q1. What is the purpose of this appendix?

A1. This appendix reviews the principles behind the risk positioning methodologies, describes the estimation of the parameters used in the models, and details the cost of capital estimates obtained from these methodologies. This appendix intentionally repeats portions of my direct testimony, because I want the reader to be able to have a full discussion of the issues addressed here, rather than having to continually turn back to the corresponding section of the testimony.

I. EQUITY RISK PREMIUM METHODOLOGY

Q2. How is this section of the appendix organized?

A2. It first reviews the basic nature of the equity risk premium approach. It then discusses the individual components of the model: the benchmark risk premium, the relative risk of the company or line of business in question, the appropriate interest rate, and the combination of these elements in a particular equity risk premium model.

A. THE BASIC EQUITY RISK PREMIUM MODEL

Q3. How does the equity risk premium model work?

A3. The equity risk premium approach estimates the cost of equity as the sum of a current interest rate and a risk premium. (It therefore is sometimes also known as the "risk premium" or the "risk positioning" approach.)

This approach may sometimes be applied informally. For example, an analyst or a commission may check the spread between interest rates and what is believed to be a reasonable estimate of the cost of capital at one time, and then apply that spread to changed interest rates to get a new estimate of the cost of capital at another time.

More formal applications of equity risk premium method implement the second approach to cost of capital estimation. They use information on all securities to identify the security market line (Figure 1 in the body of the testimony) and derive the cost of capital for the individual security based on that security's relative risk. This equity risk premium

approach is widely used and underlies most of the current scholarly research on the nature, determinants and magnitude of the cost of capital.

Q4. How are "more formal applications" put into practice?

A4. The essential benchmarks that determine the security market line are the risk-free interest rate and the premium that a security of average risk commands over the risk-free rate. This premium is commonly referred to as the "market risk premium" ("MRP"), i.e., the excess of the expected return on the average common stock over the risk-free interest rate. In the equity risk premium approach the risk-free interest rate and MRP are common to all securities. A security-specific measure of relative risk (beta) is estimated separately and combined with the MRP to obtain the company-specific risk premium.

In principle, there may be more than one factor affecting the expected stock return, each with its own security-specific measure of relative risk and its own benchmark risk premium. For example, the "arbitrage pricing theory" and other "multi-factor" models have been proposed in the academic literature. These models estimate the cost of capital as the sum of a risk-free rate and several security-specific risk premia. However, none of these alternative models has emerged in practice as "the" improvement to use instead of the original, single-factor model. I use the traditional single-factor model in this testimony.

Accordingly, the required elements in my formal equity risk premium approach are the market risk premium, an objective measure of relative risk, the risk-free rate that corresponds to the measure of the market risk premium, and a specific method to combine these elements into an estimate of the cost of capital.

B. MARKET RISK PREMIUM

Q5. Why is a risk premium necessary?

A5. Experience (e.g., the U.S. market's October Crash of 1987) demonstrates that shareholders, even well diversified shareholders, are exposed to enormous risks. By investing in stocks instead of risk-free Government bills, investors subject themselves not only to the risk of earning a return well below those they expected in any year but also to

the risk that they might lose much of their initial capital. This is why investors demand a risk premium.

I estimate two versions of the Capital Asset Pricing Model ("CAPM"). The first version measures the market risk premium as the risk premium of average risk common stocks over the long-term risk-free rate. The second version measures the risk premium relative to a short-term risk-free rate, which is the usual measure of the "market risk premium" used in capital market theories.

Q6. Please discuss some of the issues involved in selecting the appropriate MRP?

A6. To determine the cost of capital in a regulatory proceeding, the MRP should be used with a forecast of the same interest rate used to calculate the MRP (i.e., the short-term Treasury bill rate or the long-term Government rate). For example, it would be inconsistent to utilize a short-term risk-free with an estimate of the MRP derived from comparisons to long-term interest rates. In addition, the appropriate measure of the MRP should be based upon the arithmetic mean not the geometric mean return.[1] The arithmetic mean is the simple average while the geometric mean is the compound rate of return between two periods.

Q7. How do you estimate the MRP?

A7. There is presently little consensus on "best practice" for estimating the MRP, which does not mean that each approach is equally valid. For example, the latest edition of the leading graduate textbook in corporate finance, after recommending use of the arithmetic average realized excess return on the market for many years (which for a while was noticeably over 9 percent), now reviews the current state of the research and expresses the view that the a range between 5 to 8 percent is reasonable for the U.S.[2,3]

---

[1] See, for example, Morningstar, Stocks, Bonds, Bills, and Inflation: Valuation Edition 2007 Yearbook, pp. 75-77.

[2] Richard A. Brealey, Stewart C. Myers, and Franklin Allen, *Principles of Corporate Finance*, McGraw-Hill, 8th edition, 2006, pp. 151-154.

[3] In past editions, the authors expressed the view that they are "most comfortable" with values toward the upper end of that range, but this language does not appear in the 8th edition. Although Professor Myers still holds this view, this language and other sections were dropped to accommodate a request to reduce the length of the text.

My written testimony considers both the historical evidence and the results of scholarly studies of the factors that affect the risk premium for average-risk stocks in order to estimate the benchmark risk premium investors currently expect. I consider the historical difference in returns between the Standard and Poor's 500 Index ("S&P 500") and the risk-free rate, recent academic literature on the MRP and the results of recent surveys to estimate the market risk premium.

Q8. Please summarize the recent literature on the MRP and the conclusions you draw from it?

A8. Some recent research based upon U.S. data challenges the conventional wisdom of using the arithmetic average historical excess returns to estimate the MRP. However, after reviewing the issues in the debate, I remain skeptical for several reasons that the market risk premium has declined in the U.S. as much as is claimed in some of the literature.

First, despite eye-catching claims like "equity risk premium as low as three percent,"[4] and "the death of the risk premium,"[5] not all recent research arrives at the same conclusion. In his presidential address to the American Finance Association in 2001, Professor Constantinides seeks to estimate the unconditional equity premium based on average historical stock returns.[6] (Note that this address was based upon evidence just before the major fall in market value.) He adjusts the average returns downward by the change in price-earnings ratio because he assumes no change in valuations in an unconditional state. His estimates for 1926 to 2000 and 1951 to 2000 are 8.0 percent and 6.0 percent, respectively, over the 3-month T-bill rate. In another published study in 2001, Professors Harris and Marston use the DCF method to estimate the market risk premium for the U.S. stocks.[7] Using analysts' forecasts to proxy for investors' expectation, they conclude that over the period 1982-1998 the MRP over the *long-term*

risk-free rate is 7.14 percent. As yet another example, the paper by Drs. Ibbotson and Chen (2003) adopts a supply side approach to estimate the forward looking long-term sustainable equity returns and equity risk premium based upon economic fundamentals. Their equity risk premium over the *long-term* risk-free rate is estimated to be 3.97 percent in geometric terms and 5.90 percent on an arithmetic basis. They conclude their paper by stating that their estimate of the equity risk premium is "far closer to the historical premium than being zero or negative."[8]

Second, Professor Ivo Welch surveyed a large group of financial economists in 1998 and 1999. The average of the estimated MRP was 7.1 percent in Prof. Welch's first survey and 6.7 percent in his second survey which was based on a smaller number of individuals. However, a more recent survey[9] by Prof. Welch reported only a 5.5 percent MRP.[10] In characterizing these results Prof. Welch notes that "[T]he equity premium consensus forecast of finance and economics professors seems to have dropped during the last 2 to 3 years, a period with low realized equity premia."[11]

The above quotation from Prof. Welch emphasizes the caution that must attend survey data even from knowledgeable survey participants: the outcome is likely to change quickly with changing market circumstances. Regulatory commissions should not, in my opinion, attempt to keep pace with such rapidly changing opinions.

Third, some of the evidence for negative or close to zero market risk premium simply does not make sense. Despite the relatively high valuation levels, stock returns remain much more volatile than Treasury bond returns. I am not aware of any empirical or theoretical evidence showing that investors would rationally hold equities and not expect to earn a positive risk premium for bearing their higher risk.

[11] *Ibid*, p. 8.

Fourth, I am unaware of a convincing theory for why the future MRP should have substantially declined. At the height of the stock market bubble in the U.S., many claimed that the only way to justify the high stock prices would be if the MRP had declined dramatically,[12] but this argument was heard less frequently after the market declined substantially from its tech bubble high. All else equal, a high valuation ratio such as price-earnings ratio implies a low required rate of return, hence a low MRP. However, there is considerable debate about whether the high level of stock prices (despite the burst of the internet bubble from its high in the summer of 2000) represents the transition to a new economy or is simply an "irrational exuberance," which cannot be sustained for the long term. If the former case is true, then the MRP may have decreased permanently. Conversely, the long-run MRP may remain the same even if expected market returns in the short-term are smaller.

Another common argument for a lower expected MRP is that the U.S. experienced very remarkable growth in the 20th century that was not anticipated at the start of the century. As a result, the average realized excess return is overestimated meaning the standard method of estimating the MRP would be biased upward. However, one recent study by Profs. Jorion and Goetzmann finds, under some simplifying assumptions, that the so-called "survivorship bias" is only 29 basis points.[13] Furthermore, "[I]f investors have overestimated the equity premium over the second half of the last century, Constantinides (2002) argues that 'we now have a bigger puzzle on our hands' Why have investors systematically biased their estimates over such a long horizon?"[14]

---

[12] See Robert D. Arnott and Peter L. Bernstein, "What Risk Premium is 'Normal'?," *Financial Analysts Journal* 58:64-85, for an example.

[13] Jorion, P., and W. Goetzmann (1999), "Global Stock Markets in the Twentieth Century," *Journal of Finance* 54:953-980. Dimson, Marsh, and Staunton (2003) make a similar point when they comment on the equity risk premia for 16 countries based on returns between 1900 and 2001: "While the United States and the United Kingdom have indeed performed well, compared to other markets there is no indication that they are hugely out of line." p.4.

[14] Mehra, R., and E.C. Prescott (2003), "The Equity Premium in Retrospect," in *Handbook of the Economics of Finance*, Edited by G.M. Constantinides, M. Harris and R. Stulz, Elsevier B.V, p. 926

To sum up the above, I cite two passages from Profs. Mehra and Prescott's review of the theoretical literature on equity premium puzzle:[15]

> Even if the conditional equity premium given current market conditions is small, and there appears to be general consensus that it is, this in itself does not imply that it was obvious either that the historical premium was too high or that the equity premium has diminished.
>
> In the absence of this [knowledge of the future], and based on what we currently know, we can make the following claim: over the long horizon the equity premium is likely to be similar to what it has been in the past and the returns to investment in equity will continue to substantially dominate that in T-bills for investors with a long planning horizon.

Q9. Is there other scholarly support for the conclusion?

A9. Yes. Another line of research was pursued by Steven N. Kaplan and Richard S. Ruback. They estimate the market risk premium in their article, "The Valuation of Cash Flow Forecasts: An Empirical Analysis."[16] Professors Kaplan and Ruback compare published cash flow forecasts for management buyouts and leveraged recapitalization over the 1983 to 1989 period against the actual market values that resulted from these transactions. One of their results is an estimate of the market risk premium over the long-term Treasury bond yield that is based on careful analysis of actual major investment decisions, not realized market returns. Their median estimate is 7.78 percent and their mean estimate is 7.97 percent.[17] This is considerably higher than my estimate of 6.5 percent. Even if the maturity premium of Treasury bonds over Treasury bills were only 1 percent, well below the best estimate of 1.5 percent the resulting estimate of the market risk premium over Treasury bills is higher than my estimate of 8.0 percent.

[16] *Journal of Finance*, 50, September 1995, pp. 1059-1093.

[17] *Ibid*, p. 1082.

Q10. In addition to the scholarly articles and survey evidence you discussed in Section I of your Direct Testimony, what other evidence do you consider to estimate the MRP?

A10. I also consider the long-run realized equity premia reported in Morningstar *SBBI Valuation Edition 2007 Yearbook*. The data provided cover the period 1926 through 2006. The results are discussed below.

Q11. What is the "long-run realized risk premium" in the U.S.?

A11. From 1926 to 2006, the full period reported, Morningstar's data show that the average premium of stocks over Treasury bills is 8.6 percent. I also examine the "post-War" period. The risk premium for 1947-2006 is 8.4 percent.[18] (I exclude 1946 because its economic statistics are heavily influenced by the War years; e.g., the end of price controls yielded an inflation rate of 18 percent. It is not really a "post-War" year, from an economic viewpoint.) These averages often change slightly when another year of data is added to the Ibbotson series. The average premium of stocks over the income returns on long-term Government bonds is 7.1 percent for the 1926 to 2006 period and 7.1 for the 1947 to 2006 period.

Recently there has been a great deal of academic research on the MRP. This research has put practitioners in a dilemma: there is nothing close to a consensus about how the MRP should be estimated, but a general agreement in the academic community seems to be emerging that the old approach of using the average realized return over long periods gives too high an answer.

Q12. What is your conclusion regarding the MRP?

A12. Estimation of the MRP remains controversial. There is no consensus on its value or even how to estimate it. Given a careful review of all of the information, I estimate the risk premium for average risk stocks to be 8.0 percent over Treasury bills and 6.5 percent over long-term Government bonds.

[18] Morningstar, SBBI Valuation Edition 2007 Yearbook, Appendix A.

C. RELATIVE RISK

Q13. How do you measure relative risk?

A13. The risk measure I examine is the "beta" of the stocks in question. Beta is a measure of the "systematic" risk of a stock — the extent to which a stock's value fluctuates more or less than average when the market fluctuates. It is the most commonly used measure of risk in capital market theories.

Q14. Please explain beta in more detail.

A14. The basic idea behind beta is that risks that cannot be diversified away in large portfolios matter more than those that can be eliminated by diversification. Beta is a measure of the risks that *cannot* be eliminated by diversification.

Diversification is a vital concept in the study of risk and return. (Harry Markowitz won a Nobel Prize for work showing just how important it was.) Over the long run, the rate of return on the stock market has a very high standard deviation, on the order of 15 - 20 percent per year. But many individual stocks have much higher standard deviations than this. The stock market's standard deviation is "only" about 15 - 20 percent because when stocks are combined into portfolios, some of the risk of individual stocks is eliminated by diversification. Some stocks go up when others go down, and the average portfolio return — positive or negative — is usually less extreme than that of individual stocks within it.

In the limiting case, if the returns on individual stocks were completely uncorrelated with one another, the formation of a large portfolio of such stocks would eliminate risk entirely. That is, the market's long-run standard deviation would be not 15-20 percent per year, but virtually zero.

The fact that the market's actual annual standard deviation is so large means that, in practice, the returns on stocks are correlated with one another, and to a material degree. The reason is that many factors that make a particular stock go up or down also affect other stocks. Examples include the state of the economy, the balance of trade, and inflation. Thus some risk is "non-diversifiable". Single-factor equity risk premium models derive conditions in which all of these factors can be considered simultaneously,

through their impact on the market portfolio. Other models derive somewhat less restrictive conditions under which several of them might be individually relevant.

Again, the basic idea behind all of these models is that risks that cannot be diversified away in large portfolios matter more than those that can be eliminated by diversification, because there are a large number of large portfolios whose managers actively seek the best risk-reward tradeoffs available. Of course, undiversified investors would like to get a premium for bearing diversifiable risk, but they cannot.

Q15. Why not?

A15. Well-diversified investors compete away any premium rates of return for diversifiable risk. Suppose a stock were priced especially low because it had especially high diversifiable risk. Then it would seem to be a bargain to well diversified investors. For example, suppose an industry is subject to active competition, so there is a large risk of loss of market share. Investors who held a portfolio of all companies in the industry would be immune to this risk, because the loss on one company's stock would be offset by a gain on another's stock. (Of course, the competition might make the whole industry more vulnerable to the business cycle, but the issue here is the diversifiable risk of shifts in market share among firms.)

If the shares were priced especially low because of the risk of a shift in market shares, investors who could hold shares of the whole industry would snap them up. Their buying would drive up the stocks' prices until the premium rates of return for diversifiable risk were eliminated. Since all investors pay the same price, even those who are not diversified can expect no premium for bearing diversifiable risk.

Of course, substantial non–diversifiable risk remains, as the October Crash of 1987 demonstrates. Even an investor who held a portfolio of all traded stocks could not diversify against that type of risk. Sensitivity to such market–wide movements is what beta measures. That type of sensitivity, whether considered in a single- or multi-factor model, determines the risk premium in the cost of equity.

Q16. What does a particular value of beta signify?

A16. By definition, a stock with a beta equal to 1.0 has average non-diversifiable risk: it goes up or down by 10 percent on average when the market goes up or down by 10 percent. Stocks with betas above 1.0 exaggerate the swings in the market: stocks with betas of 2.0 tend to fall 20 percent when the market falls 10 percent, for example. Stocks with betas below 1.0 are less volatile than the market. A stock with a beta of 0.5 will tend to rise 5 percent when the market rises 10 percent.

Q17. How is beta measured?

A17. The usual approach to calculating beta is a statistical comparison of the sensitivity of a stock's (or a portfolio's) return to the market's return. Many investment services report betas, including Merrill Lynch's quarterly Security Risk Evaluation, Bloomberg and the *Value Line Investment Survey*. Betas are not always calculated the same way, and therefore must be used with a degree of caution, but the basic point that a high beta indicates a risky stock has long been widely accepted by both financial theorists and investment professionals.

Q18. Are there circumstances when the "usual approach to calculating beta" should not be used?

A18. There are at least two cases where the standard estimate of beta should be viewed skeptically.

First, companies in serious financial distress seem to "decouple" from their normal sensitivity to the stock market. The stock prices of financially distressed companies tend to change based more on individual news about their particular circumstances than upon overall market movements. Thus, a risky stock could have a low estimated beta if the company was in financial distress. Other circumstances that may cause a company's stock to decouple include an industry restructuring or major changes in a company's supply or output markets.

Second, similar circumstances seem to arise for companies "in play" during a merger or acquisition. Once again, the individual information about the progress of the proposed

takeover is so much more important for that stock than day-to-day market fluctuations that, in practice, beta estimates for such companies seem to be too low.

Q19. How reliable is beta as a risk measure?

A19. Scholarly studies have long confirmed the importance of beta for a stock's required rate of return. It is widely regarded as the best single risk measure available. The merits of beta seemed to have been challenged by widely publicized work by Professors Eugene F. Fama and Kenneth R. French.[19] However, despite the early press reports of their work as signifying that "beta is dead," it turns out that beta is still a potentially important explanatory factor (albeit one of several) in their work. Thus, beta remains alive and well as the best single measure of relative risk.

D. INTEREST RATE FORECAST

Q20. What interest rates do your procedures require?

A20. Modern capital market theories of risk and return use the short-term risk-free rate of return as the starting benchmark. My measures of the MRP incorporate this approach, since they represent the excess of the expected return on the market over the 30-day U.S. Treasury bill rate and over the long-term U.S. Government bond rate. Accordingly, implementation of my procedures requires use of a forecast of the 30-day Treasury bill rate and the long-term Government bond rate.

E. COST OF CAPITAL MODELS

Q21. How do you combine the above components into an estimate of the cost of capital?

A21. By far the most widely used approach to estimation of the cost of capital is the "Capital Asset Pricing Model," and I do calculate CAPM estimates. However, the CAPM is only one equity risk premium approach technique, and I also use another.

[19] See for example, "The Capital Asset Pricing Model: Theory and Evidence", Eugene F. Fama and Kenneth R. French, *Journal of Economic Perspectives*, Volume 18, Summer 2004, pp. 25-46.

Q22. Please start with the CAPM, by describing the model.

A22. As noted above, the modern models of capital market equilibrium express the cost of equity as the sum of a risk-free rate and a risk premium. The CAPM is the longest-standing and most widely used of these theories. The CAPM states that the cost of capital for investment s (e.g., a particular common stock) is given by the following equation:

$$k_s = r_f + \beta_s \times MRP \qquad \textbf{(C-1)}$$

where k_s is the cost of capital for investment s; r_f is the risk-free rate, β_s is the beta risk measure for the investment s; and MRP is the market risk premium.

The CAPM relies on the empirical fact that investors price risky securities to offer a higher expected rate of return than safe securities do. It says that the security market line starts at the risk-free interest rate (that is, that the return on a zero-risk security, the y-axis intercept in Figure 1 in the body of my testimony, equals the risk-free interest rate). Further, it says that the risk premium over the risk-free rate equals the product of beta and the risk premium on a value-weighted portfolio of all investments, which by definition has average risk.

Q23. What other equity risk premium approach model do you use?

A23. Empirical research has long shown that the CAPM tends to overstate the actual sensitivity of the cost of capital to beta: low-beta stocks tend to have higher risk premia than predicted by the CAPM and high-beta stocks tend to have lower risk premia than predicted. A number of variations on the original CAPM theory have been proposed to explain this finding. The difference between the CAPM and the type of relationship identified in the empirical studies is depicted in Figure MJV-C1.

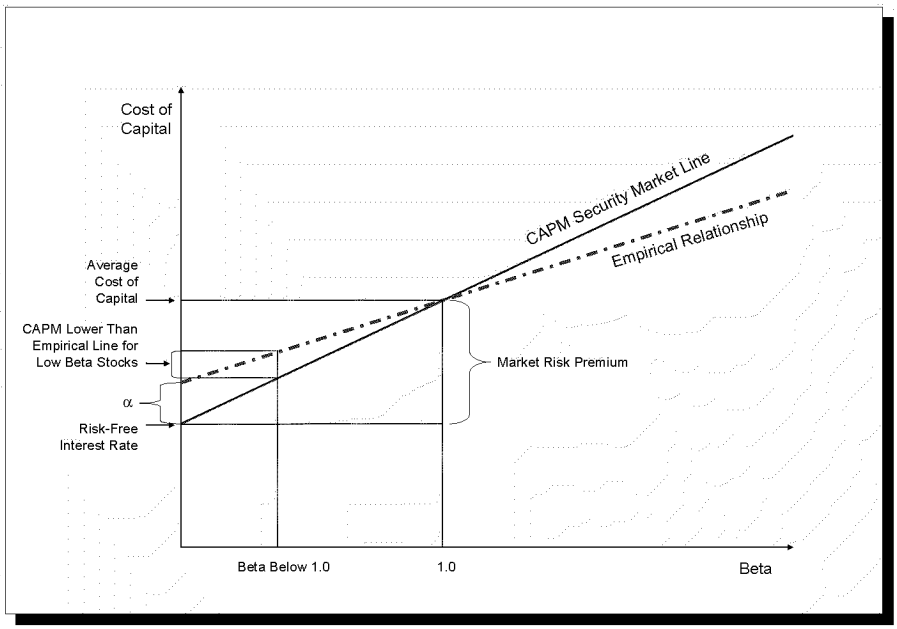

Figure MJV-C1: The Empirical Security Market Line

The second model makes use of these empirical findings. It estimates the cost of capital with the equation,

$$k_s = r_f + \alpha + \beta_s \times (MRP - \alpha) \qquad \textbf{(C-2)}$$

where α is the "alpha" of the risk-return line, a constant, and the other symbols are defined as above. I label this model the Empirical Capital Asset Pricing Model, or "ECAPM." For the short-term risk-free rate models, I set alpha equal to 1, 2, and 3 percent which are values somewhat lower than that estimated empirically. For low-beta stocks such as regulated utilities, the use of a lower value for alpha leads to a lower estimate of the cost of capital. For the long-term risk-free rate models, I set alpha equal to both 0.5 percent and 1.5 percent, but I rely more heavily on the 0.5 percent results. The use of a long-term risk-free rate incorporates some of the desired effect of using the ECAPM. That is, the long-term risk-free rate version of the Security Market Line has a higher intercept and a flatter slope than the short-term risk-free version which has been tested. Thus, it is likely that I do not need to make the same degree adjustment when I use the long-term risk-free rate. A summary of the empirical evidence on the magnitude of alpha is provided in Table No. MJV-C1 below.

II. EMPIRICAL EQUITY RISK PREMIUM RESULTS

Q24. How is this part of the appendix organized?

A24. This section presents the full details of my equity risk premium approach analyses, which are summarized in the body of my testimony. Details behind the forecasts of the short-term and the long-term risk-free interest rates are discussed. Next, the beta estimates, and the estimates of the MRP I use in the models are addressed. Finally, this section reports the CAPM and ECAPM results for the sample's costs of equity, and then describes the results of adjusting for differences between the benchmark sample and the Ohio EDUs' regulated capital structures.

A. RISK-FREE INTEREST RATE FORECAST

Q25. How do you obtain the forecasts of the risk-free interest rates over the period the utility rates set here are to be in effect?

A25. I obtain these forecast rates using data provided by Bloomberg. In particular, I use their reported government debt yields from the "constant maturity series". This information is displayed in Panels A and B of Table No. MJV-9.

Q26. What values do you use for the short-term and long-term risk-free interest rates?

A26. I use a value of 3.8 percent for the short-term risk-free interest rate and a value of 4.9 percent for the long-term risk-free interest rate as the benchmark interest rates in the equity risk premium analyses. These forecasts are constructed by using historical yield curve data to find the long-run average implied term premia on government securities, and combining these with recent yield curve data. Details of their calculation can be found in the Workpapers to Table No. MJV-9.

B. BETAS AND THE MARKET RISK PREMIUM

1. Beta Estimation Procedures

Q27. How do you estimate beta?

A27. I use the beta estimates reported in the *Value Line* for the sample companies. The current *Value Line* beta estimates range from 0.70 to 1.30 for the benchmark sample (See Workpaper #1 to Table No. MJV-10).

2. Market Risk Premium Estimation

Q28. Given all of the evidence, what MRP do you use in your analysis?

A28. It is clear that market return information is volatile and difficult to interpret, but based on the collective evidence, the MRP I use for the short-term risk-free rate is 8 percent and for the long-term risk-free rate is 6.5 percent.

C. COST OF CAPITAL ESTIMATES

Q29. Based on these data, what are the values you calculate for the overall cost of capital and the corresponding cost of equity for the sample?

A29. Panels A and B of Table No. MJV-10 present the cost of equity results using the equity risk positioning methods. Panel A uses the long-term risk-free rate forecast while Panel B uses the short-term risk-free rate forecast. These returns on equity are replicated and the overall cost of capital for the various equity risk positioning methods are reported in Table No. MJV-11, Panels A to G. Panels A through C utilize the long-term risk-free rate while Panels D through G use the short-term risk free rate. Panel A reports the cost of capital estimates using the CAPM results for the long-term risk-free rate, while Panels B and C report these estimates for the ECAPM cost of equity results using ECAPM parameters of 0.5 and 1.5 percent, respectively. Panel D reports the CAPM estimates using the short-term risk free rate, while Panels E, F and G report ECAPM results using ECAPM parameters of 1, 2 and 3 respectively. In each panel, column [8] reports the overall cost of capital for each company. The last row of each panel reports the sample average.

Q30. What does the sample market data imply about the sample's cost of equity at the proposed 49 percent equity ratio for the Ohio EDUs?

A30. The sample average ATWACC from each panel of Table No. MJV-11 is reproduced in column [1] of Table No. MJV-12, which then reports the cost of equity for each of the risk positioning methods that is consistent with the sample information and the capital structure of the Ohio EDUs. The sample average ATWACCs and corresponding costs of equity at a 49 percent equity ratio are also displayed in Table 3 of my testimony.

I discuss the implications of the equity risk positioning results for the sample in the main body of my testimony.

Table MJV-C1

EMPIRICAL EVIDENCE ON THE ALPHA FACTOR IN ECAPM*		
AUTHOR	RANGE OF ALPHA	PERIOD RELIED UPON
Black (1993)[1]	1% for betas 0 to 0.80	1931-1991
Black, Jensen and Scholes (1972)[2]	4.31%	1931-1965
Fama and McBeth (1972)	5.76%	1935-1968
Fama and French (1992)[3]	7.32%	1941-1990
Litzenberger and Ramaswamy (1979)[4]	5.32%	1936-1977
Litzenberger, Ramaswamy and Sosin (1980)	1.63% to 3.91%	1926-1978
Pettengill, Sundaram and Mathur (1995)[5]	4.6%	1936-1990

*The figures reported in this table are for the longest estimation period available and, when applicable, use the authors' recommended estimation technique. Many of the articles cited also estimate alpha for sub-periods and those alphas may vary.

[1]Black estimates alpha in a one step procedure rather than in an un-biased two-step procedure.

[2]Estimate a negative alpha for the subperiod 1931-39 which contain the depression years 1931-33 and 1937-39.

[3]Calculated using Ibbotson's data for the 30-day treasury yield.

[4]Relies on Lizenberger and Ramaswamy's before-tax estimation results. Comparable after-tax alpha estimate is 4.4%.

[5]Pettengill, Sundaram and Mathur rely on total returns for the period 1936 through 1990 and use 90-day treasuries. The 4.6% figure is calculated using auction averages 90-day treasuries back to 1941 as no other series were found this far back.

APPENDIX D

DISCOUNTED CASH FLOW METHODOLOGY:

DETAILED PRINCIPLES AND RESULTS

I. DISCOUNTED CASH FLOW METHODOLOGY PRINCIPLES D-1

A. SIMPLE AND MULTI-STAGE DISCOUNTED CASH FLOW MODELS D-1

B. CONCLUSIONS ABOUT DCF D-7

II. EMPIRICAL DCF RESULTS D-7

A. PRELIMINARY MATTERS D-8

B. GROWTH RATES D-8

C. DIVIDEND AND PRICE INPUTS D-11

D. COMPANY-SPECIFIC DCF COST OF CAPITAL ESTIMATES D-12

Q1. What is the purpose of this appendix?

A1. This appendix reviews the principles behind the discounted cash flow or "DCF" methodology and the details of the cost of capital estimates obtained from this methodology.

I. DISCOUNTED CASH FLOW METHODOLOGY PRINCIPLES

Q2. How is this section of the appendix organized?

A2. The first part discusses the general principles that underlie the DCF approach. The second portion describes the strengths and weaknesses of the DCF model and why it is generally less reliable for estimating the cost of capital for the sample companies at the present time than the risk positioning method discussed in Appendix C.

A. SIMPLE AND MULTI-STAGE DISCOUNTED CASH FLOW MODELS

Q3. Please summarize the DCF model.

A3. The DCF model takes the first approach to cost of capital estimation discussed with Figure 1 in Section II-A of my direct testimony. That is, it attempts to measure the cost of equity in one step. The method assumes that the market price of a stock is equal to the present value of the dividends that its owners expect to receive. The method also assumes that this present value can be calculated by the standard formula for the present value of a cash flow stream:

$$P = \frac{D_1}{(1+k)} + \frac{D_2}{(1+k)^2} + \frac{D_3}{(1+k)^3} + \cdots + \frac{D_T}{(1+k)^T} \qquad \textbf{(D-1)}$$

where "P" is the market price of the stock; "D_i" is the dividend cash flow expected at the end of period i; "k" is the cost of capital; and "T" is the last period in which a dividend cash flow is to be received. The formula just says that the stock price is equal to the sum of the expected future dividends, each discounted for the time and risk between now and the time the dividend is expected to be received.

Most DCF applications go even further, and make very strong (*i.e.*, unrealistic) assumptions that yield a simplification of the standard formula, which then can be

rearranged to estimate the cost of capital. Specifically, if investors expect a dividend stream that will grow forever at a steady rate, the market price of the stock will be given by a very simple formula,

$$P = \frac{D_1}{(k-g)} \qquad \textbf{(D-2)}$$

where "D_1" is the dividend expected at the end of the first period, "g" is the perpetual growth rate, and "P" and "k" are the market price and the cost of capital, as before. Equation D-2 is a simplified version of Equation D-1 that can be solved to yield the well known "DCF formula" for the cost of capital:

$$\begin{aligned} k &= \frac{D_1}{P} + g \\ &= \frac{D_0 \times (1+g)}{P} + g \end{aligned} \qquad \textbf{(D-3)}$$

where "D_0" is the current dividend, which investors expect to increase at rate g by the end of the next period, and the other symbols are defined as before. Equation D-3 says that if Equation D-2 holds, the cost of capital equals the expected dividend yield plus the (perpetual) expected future growth rate of dividends. I refer to this as the simple DCF model. Of course, the "simple" model is simple because it relies on very strong (*i.e.*, very unrealistic) assumptions.

Q4. Are there other versions of the DCF models besides the "simple" one?

A4. Yes. If Equation D-2 and its underlying assumptions do not hold, sometimes other variations of the general present value formula, Equation D-1, can be used to solve for k in ways that differ from Equation D-3. For example, if there is reason to believe that investors do *not* expect a steady growth rate forever, but rather have different growth rate forecasts in the near term (e.g., over the next five or ten years as compared with subsequent periods), these forecasts can be used to specify the early dividends in Equation D-1. Once the near-term dividends are specified, Equation D-2 can be used to specify the share price value at the end of the near-term (e.g., at the end of five or ten years), and the resulting cash flow stream can be solved for the cost of capital using Equation D-1.

More formally, the "multi-stage" DCF approach solves the following equation for k:

$$P = \frac{D_1}{(1+k)} + \frac{D_2}{(1+k)^2} + \frac{D_3}{(1+k)^3} + \cdots + \frac{D_T + P_{TERM}}{(1+k)^T} \quad \textbf{(D-4)}$$

The terminal price, P_{TERM} is estimated as

$$P_{TERM} = \frac{D_{T+1}}{(k - g_{LR})} \quad \textbf{(D-5)}$$

where T is the last of the periods in which a near term dividend forecast is made and g_{LR} is the long-run growth rate. Thus, Equation D-4 defers adoption of the very strong perpetual growth assumptions that underlie Equation D-2 — and hence the simple DCF formula, Equation D-3 — for as long as possible, and instead relies on near term knowledge to improve the estimate of k. I examine both simple and multi-stage DCF results below.

Q5. What are the merits of the DCF model?

A5. The DCF approach is conceptually sound only if its assumptions are met. In actual practice one can run into difficulty because those assumptions are so strong, and hence so unlikely to correspond to reality. Two conditions are well-known to be necessary for the DCF approach to yield a reliable estimate of the cost of capital: the variant of the present value formula, Equation D-1, that is used must actually match the variations in investor expectations for the dividend growth path; and the growth rate(s) used in that formula must match current investor expectations. Less frequently noted conditions may also create problems.

The DCF model assumes that investors expect the cost of capital to be the same in all future years. Investors may not expect the cost of capital to be the same, which can bias the DCF estimate of the cost of capital in either direction.

The DCF model only works for companies for which the standard present value formula works. The standard formula does *not* work for companies that operate in industries or markets options (*e.g.*, puts and calls on common stocks), and so it will not work for companies whose stocks behave as options do. Option-pricing effects will be important

for companies in financial distress, for example, which implies the DCF model will *understate* their cost of capital, all else equal.

In recent years even the most basic DCF assumption, that the market price of a stock in the absence of growth options is given by the standard present value formula (*i.e.*, by Equation D-1 above), has been called into question by a literature on market volatility.[1] In any case, it is still too early to throw out the standard formula, if for no other reasons than that the evidence is still controversial and no one has offered a good replacement. But the evidence suggests that it must be viewed with more caution than financial analysts have traditionally applied. Simple models of stock prices may not be consistent with the available evidence on stock market volatility.

Q6. Normally DCF debates center on the right growth rate. What principles underlie that choice?

A6. Finding the right growth rate(s) is indeed the usual "hard part" of a DCF application. The original approach to estimation of g relied on average historical growth rates in observable variables, such as dividends or earnings, or on the "sustainable growth" approach, which estimates g as the average book rate of return times the fraction of earnings retained within the firm. But it is highly unlikely that historical averages over periods with widely varying rates of inflation, interest rates and costs of capital, such as in the relatively recent past, will equal current growth rate expectations.

A better approach is to use the growth rates currently expected by investment analysts, if an adequate sample of such rates is available. If this approach is feasible and if the person estimating the cost of capital is able to select the appropriate version of the DCF formula, the DCF method should yield a reasonable estimate of the cost of capital for

[1] See for example, Robert J. Shiller (1981), "Do Stock Prices Move Too Much to be Justified by Subsequent Changes in Dividends?," *The American Economic Review*, Vol. 71, No. 3, pp. 421-436. John Y. Campbell and Robert J. Shiller (1988), "The Dividend-Price Ratio and Expectations of Future Dividends and Discount Factors," *The Review of Financial Studies*, Vol. 1, No. 3, pp. 195-228. Lucy F. Ackert and Brian F. Smith (1993), "Stock Price Volatility, Ordinary Dividends, and Other Cash Flows to Shareholders," *Journal of Finance*, Vol. 48, No. 1, pp. 1147-1160. Eugene F. Fama and Kenneth R. French (2001), "Disappearing Dividends: Changing Firm Characteristics or Lower Propensity to Pay?," *Journal of Financial Economics*, Vol. 60, pp. 3-43. Borja Larrain and Motohiro Yogo (2005), "Does Firm Value Move Too Much to be Justified by Subsequent Changes in Cash Flow?," Federal Reserve Bank of Boston, *Working Paper*, No. 05-18.

companies not in financial distress and without material option-pricing effects (always subject to recent concerns about the applicability of the basic present value formula to stock prices as well as issues of optimism bias). However, for the DCF approach to work, the basic stable-growth assumption must become reasonable and the underlying stable-growth rate must become determinable *within the period for which forecasts are available*.

Q7. What is the so called "optimism bias" in the earnings growth rate forecasts of security analysts and what is its effect on the DCF analysis?

A7. Optimism bias is related to the observed tendency for analysts to forecast earnings growth rates that are higher than are actually achieved. This tendency to over estimate growth rates is perhaps related to incentives faced by analysts that provide rewards not strictly based upon the accuracy of the forecasts. To the extent optimism bias is present in the analysts' earnings forecasts, the cost of capital estimates from the DCF model would be too high.

Q8. Does optimism bias mean that the DCF estimates are completely unreliable?

A8. No. The effect of optimism bias is least likely to affect DCF estimates for large, rate regulated companies in relatively stable segments of an industry. Furthermore, the magnitude of the optimism bias (if any) for regulated companies is not clear. This issue is addressed in a paper by Chan, Karceski, and Lakonishok (2003)[2] who sort companies on the basis of the size of the I/B/E/S forecasts to test the level of optimism bias. Utilities constitute 25 percent of the companies in lowest quintile, and by one measure the level of optimism bias is 4 percent. However, the 4 percent figure does not represent the complete characterization of the results in the paper. Table IX of the paper shows that the median I/B/E/S forecast for the first (lowest) quintile averages 6.0 percent. The realized "Income before Extraordinary Items" is 2.0 percent (implying a four percent upward bias in I/B/E/S forecasts), but the "Portfolio Income before Extraordinary Items" is 8.0 percent (implying a two percent downward bias in I/B/E/S forecasts).

[2] L. K.C. Chan, J. Karceski, and J. Lakonishok, 2003, "The Level and Persistence of Growth Rates," *Journal of Finance* 58(2):643-684.

The difference between the "Income before Extraordinary Items" and "Portfolio Income before Extraordinary Items" is whether individual firms or a portfolio are used in estimating the realized returns. The first is a simple average of all firms in the quintile while the second is a market value weighted-average. Although both measures of bias have their own drawbacks according to the authors,[3] the Portfolio Income measure gives more weight to the larger firms in the quintile such as regulated utilities. In addition, the paper demonstrates that "analysts' forecasts as well as investors' valuations reflect a wide-spread belief in the investment community that many firms can achieve streaks of high growth in earnings."[4] Therefore, it is not clear how severe the problem of optimism bias may be for regulated utilities or even whether there is a problem at all.

Finally, the two-stage DCF model also adjusts for any over optimistic (or pessimistic) growth rate forecasts by substituting the long-term GDP growth rate for the 5-year growth rate forecasts of the analysts in the years beginning in year 11. I linearly trend the 5-year forecast growth rate to the GDP forecast growth rate in years 6 to 10.

Q9. What about the reforms by the National Associate of Security Dealers (NASD) that were designed to reduce the conflicts of interest and pressures brought against security analysts? Have those reforms been generally successful?

A9. Yes. The conclusion from the Joint Report by NASD and the New York Stock Exchange ("NYSE") on the reforms states

> … the SRO Rules have been effective in helping restore integrity to research by minimizing the influences of investment banking and promoting transparency of other potential conflicts of interest. Evidence also suggests that investors are benefiting from more balanced and accurate research to aid their investment decisions.[5]

[3] Chan, Karceski, and Lakonishok, *op. cit.*, p. 675.

[4] Chan, Karceski, and Lakonishok, *op. cit.*, p. 663.

[5] Joint Report by NASD and NYSE on the Operation and Effectiveness of the Research Analyst Conflict of Interest Rules, December 2005, p. 44.

The report does note additional reforms are advisable, but the situation is far different today than during the height of the tech bubble when analyst objectivity was clearly suspect.

B. CONCLUSIONS ABOUT DCF

Q10. Please sum up the implications of this part of the appendix.

A10. The unavoidable questions about the DCF model's strong assumptions — whether the basic present value formula works for stocks, whether option pricing effects are important for the company, whether the right variant of the basic formula has been found, and whether the true growth rate expectations have been identified — cause me to view the DCF method as *inherently* less reliable than equity risk premium approach, the other approach I use. However, because the DCF method has been widely used in the past and in other forums when the industry's economic conditions were different from today's, I submit DCF evidence in this case. DCF estimates also serve as a check on the values provided by the risk positioning approach methods.

II. EMPIRICAL DCF RESULTS

Q11. How is this part of the appendix organized?

A11. This section presents the details of my DCF analyses for the sample, which are summarized in my written testimony. The first part describes some preliminary matters, such as the calculation of market value capital structures of the sample companies and the determination of the growth rates. It then turns to the details of the DCF estimates themselves.

In particular, implementation of the simple DCF models described above requires an estimate of the current price, the dividend, and near-term and long-run growth rate forecasts. The simple DCF model relies only on a single growth rate forecast, while the multistage DCF model employs both near-term individual company forecasts and long-run GDP growth rate forecasts. The remaining parts of this section describe each of these inputs in turn.

A. PRELIMINARY MATTERS

Q12. In Appendix C you discuss estimating cost of capital and implied cost of equity using the risk positioning methodology. What, if anything, is different when you use the DCF method?

A12. First, the timing of the market value capital structure calculations is different in the DCF method than in the equity risk premium method. The equity risk premium method relies on the average capital structure over the five-year period *Value Line* uses to estimate beta while the DCF approach uses only current data, so the relevant market value capital structure measure is the most recent that can be calculated. This capital structure is reported in columns [1]-[3] of Table No. MJV-4.

B. GROWTH RATES

Q13. What growth rates do you use?

A13. For reasons discussed above, historical growth rates today are generally unreliable as forecasts of current investor expectations for the electric utility industry. I therefore use rates forecasted by security analysts.

The ideal in a DCF application would be a detailed forecast of future dividends, year by year well into the future, based on a large sample of investment analysts' expectations. I know of no source of such data. Dividends are ultimately paid from earnings, however, and earnings forecasts are available for a few years. Investors do not expect dividends to grow in lockstep with earnings, but for companies for which the DCF approach can be used reliably (*i.e.*, for relatively stable companies whose prices do not include the option-like values described previously), they do expect dividends to track earnings over the long-run. Thus, use of earnings growth rates as a proxy for expectations of dividend growth rates is a common practice.

Accordingly, the first step in my DCF analysis is to examine a sample of investment analysts' forecasted earnings growth rates. In particular, I utilize Bloomberg's BEst and

Value Line's forecasted earnings growth.[6] The projected earnings growth rates for the sample companies are in Table No. MJV-5.[7] Column [1] reports Bloomberg's BEst analysts' forecasts of the long-term earnings growth for the sample companies. Column [2] reports the number of analysts that provided a forecast. Columns [3] and [4] report *Value Line's* forecasted earnings per share ("EPS") value for each company for 2008 and 2010-2012 respectively. Column [5] provides *Value Line's* implied long-term growth rate forecast, and column [6] provides a weighted average growth rate for each company across the two sources. (I treat the *Value Line* forecasts as though they overlap exactly with the forecasts from Bloomberg.) These growth rates underlie my simple and multi-stage DCF analyses.

In particular, the five-year average annual growth rate is the perpetual growth rate I employ in the simple DCF model.[8] In the multi-stage model, I rely on the company-specific growth rate until 2012 and on the long-term GDP forecast for year 2017 onwards. During the years from 2012 to 2016, I assume the growth rate converges linearly towards the long-term GDP forecast.[9]

Q14. Do these growth rates correspond to the ideal you mentioned above?

A14. No, not completely. While forecasted growth rates are the quantity required in principle, the forecasts need to go far enough out into the future so that it is reasonable to believe that investors expect a stable growth path afterwards. As can be seen from Table No. MJV-5, the growth rate estimates do not support the view that investors are expecting growth rates equal to the single perpetual growth rate assumed in the simple DCF model. Indeed, there is substantial variation across companies' combined growth rates. For example, Cleco Corp and PPL each have a combined growth rate estimate of over 12

---

[6] The BEst growth rates were downloaded from Bloomberg on April 9, 2007. *Value Line* numbers are their most recent available, variously dated December 29th, 2006, February 9, 2007, and March 2, 2007. (See Table No. MJV-5.)

[7] No Bloomberg BEst growth rate was available for MGE Energy Inc. at the time of this document's production.

[8] This growth rate is in column [6] of Table No. MJV-5.

[9] I use the long-term U.S. GDP growth estimate from *Blue Chip Economic Indicators* (March 10, 2007).

percent, while Consolidated Edison's combined estimate is 3.5 percent and Pinnacle West's is 2.9 percent (see column [6], Table No. MJV-5).

It should be noted that except for MGE Energy, there are at least two analyst estimates for all of the sample companies, though Cleco Corp and Empire Electric have only two. The comparison between the average growth rate forecasts and the growth in GDP forecast indicates that these growth rates may be overly optimistic in the case of some electric companies.

Q15. How well are the conditions needed for DCF reliability met at present?

A15. The requisite conditions for the sample companies are not fully met at this time. Of particular concern for this proceeding is the uncertainty about what investors truly expect the long-run outlook for the sample companies to be. The longest time period available for growth rate forecasts of which I am aware is five years. The long-run growth rate (*i.e.*, the growth rate after the energy industry settles into a steady state, which is certainly *beyond* the next five years for this industry) drives the actual results one gets with the DCF model. Unfortunately, this implies that unless the company or industry in question is stable, so there is little doubt as to the growth rate investors expect. DCF results in practice can end up being driven by the subjective judgment of the analyst who performs the work.

This is a problem at present because it is hard to imagine that today's energy industry would accurately be described as stable. Inflation and interest rates have largely stabilized over the last 10 years, but oil and natural gas prices have increased dramatically. The prices of natural gas and petroleum have also exhibited a great deal of volatility recently. These factors make demand for natural gas and electricity more uncertain. Additionally, the electric industry (as well as both the pipeline industry and the gas distribution sector) are going through a series of mergers and acquisitions, which affects the companies' earnings growth rate estimates. This is one reason why companies heavily involved in mergers and acquisitions are normally excluded from the sample. A number of states are actively considering reversing the restructuring process for the electric utility industry. There has also been financial distress among companies

specializing in trading natural gas and electricity products which affects both regulated and unregulated companies. Taken together, these factors mean that it may be some time before the energy industry settles into anything investors will see as a stable equilibrium.

Such circumstances imply that a regulator may often be faced with a wide range of DCF numbers, none of which can be well grounded in objective data on true long-run growth expectations, *because no such objective data now exist*. DCF for firms or industries in flux is *inherently* subjective with regard to a parameter (the long-run growth rate) that drives the answer one gets.

It is clear that much longer detailed growth rate forecasts than currently available from Bloomberg and *Value Line* would be needed to implement the DCF model in a completely reliable way for the sample at this time.

C. DIVIDEND AND PRICE INPUTS

Q16. What values do you use for dividends and stock prices?

A16. Dividends are the last recorded dividend payments as reported by Bloomberg, the 4th-quarter 2006 dividend. This dividend is grown at the estimated growth rate and divided by the price described below to estimate the dividend yield for the simple and multi-stage DCF models.

For the sample calculations, stock prices are the average of the closing stock prices for the 15 trading days (approximately three weeks) ending April 9, 2007 for each company, the same date growth rate estimates were pulled from Bloomberg. I do not use a longer period to measure the price, because that would be inconsistent with the principles that underlie the DCF formula. The DCF approach assumes the stock price is the present value of future expected dividends. Stock prices six months or a year ago reflect expectations at that time, which are different from those that underlie the currently available growth forecasts. At the same time, use of an average over a brief period helps guard against a company's price on a particular day price being unduly influenced by mistaken information, differences in trading frequency, and the like.

The closing stock price is used because it is at least as good as any other measure of the day's outcome, and may be better for DCF purposes. In particular, if there were any single price during the day that would affect investors' decisions to buy or sell a stock, I would suspect that it would be each day's closing price, not the high or low during the day. The daily price changes reported in the financial pages, for example, are from close to close, not from high to high or from low to low.

D. COMPANY-SPECIFIC DCF COST OF CAPITAL ESTIMATES

Q17. What DCF estimates do these data yield?

A17. The cost of equity results for the simple and multistage DCF models are shown in Table No. MJV-6. Panel A reports the results for the simple DCF method while Panel B reports the results for the multistage DCF method using the long-term GDP growth rate as the perpetual growth rate.

Q18. What overall cost of capital estimates result from the DCF cost of equity estimates?

A18. The capital structure, DCF cost of equity, and cost of debt estimates are combined to obtain the overall after-tax weighted-average cost of capital for each sample company. These results are presented in Table No. MJV-7. Again, Panel A relies on the simple DCF cost of equity results while Panel B relies on the multistage DCF cost of equity results.

Q19. What information do you report in Table No. MJV-8?

A19. This table reports the return on equity consistent with the sample's estimated overall after-tax weighted-average cost of capital and the proposed equity thickness of 49 percent for the Ohio EDUs. For both the simple DCF and multistage DCF methods, the sample's average ATWACC is reported in column [1]. Column [6] reports the return on equity as if the sample companies' average market value capital structure had been that currently proposed for the Ohio EDUs.

Q20. What are the implications of these results?

A20. The implication of these numbers is discussed in my written testimony, along with the findings of the equity risk premium approach.

APPENDIX E

EFFECT OF DEBT ON THE COST OF EQUITY

I. AN OVERVIEW OF THE ECONOMIC LITERATURE E-1

A. TAX EFFECTS E-1
1. Base Case: No Taxes, No Risk to High Debt Ratios E-2
2. Corporate Tax Deduction for Interest Expense E-3
3. Personal Tax Burden on Interest Expense E-4

B. NON-TAX EFFECTS E-7

II. EXPANDED EXAMPLE E-11

A. DETAILS OF DIFFERENT LEVELS OF DEBT E-11

B. THE IMPACT OF INCOME AND INTEREST E-15

C. THE EFFECT OF TAXES E-18

D. COMBINED EFFECTS E-23

Q1. What is the purpose of this Appendix?

A1. In this appendix, I provide details on the effects of debt on the cost of equity. First, I summarize a fairly large body of financial research on capital structure. Second, I provide an extended example to illustrate the effect of debt on the cost of equity.

I. AN OVERVIEW OF THE ECONOMIC LITERATURE

Q2. What is the focus of the economic literature on the effects of debt?

A2. The economic literature focuses on the effects of debt on the value of a firm. The standard way to recognize one of these effects, the impact of the fact that interest expense is tax-deductible, is to discount the all-equity after-tax operating cash flows generated by a firm or an investment project at a weighted average cost of capital, typically known in textbooks as the "WACC." The textbook WACC equals the *market*-value weighted average of the cost of equity and the *after-tax*, *current* cost of debt. However, rate regulation in North America has a legacy of working with another weighted-average cost of capital, the *book*-value weighted average of the cost of equity and the *before-tax*, *embedded* cost of debt. To distinguish the concepts, I refer to the after-tax weighted-average cost of capital as ATWACC.

Q3. How is this section of the appendix organized?

A3. It starts with the tax effects of debt. It then turns to other effects of debt.

A. TAX EFFECTS

Q4. What are the key findings in the literature regarding tax effects?

A4. Three seminal papers are vital for this literature. The first assumes no taxes and risk-free debt. The second adds corporate income taxes. The third adds personal income taxes.

1. Base Case: No Taxes, No Risk to High Debt Ratios

Q5. Please start by explaining the simplest case of the effect of debt on the value of a firm.

A5. The "base case," no taxes and no costs to excessive debt, was worked out in a classic 1958 paper by Franco Modigliani and Merton Miller, two economists who eventually won Nobel Prizes in part for their body of work on the effects of debt.[1] Their 1958 paper made what is in retrospect a very simple point: if there are no taxes and no risk to the use of excessive debt, use of debt will have no effect on a company's operating cash flows (i.e., the cash flows to investors as a group, debt plus equity combined). If the operating cash flows are the same regardless of whether the company finances mostly with debt or mostly with equity, then the value of the firm cannot be affected at all by the debt ratio. In cost of capital terms, this means the overall cost of capital is constant regardless of the debt ratio, too.

In the base case, issuing debt merely divides the cash flows into two pools, one for bondholders and one for shareholders. If the divided pools have different priorities in claims on the cash flows, the risks and costs of capital will differ for each pool. But the risk and overall cost of capital of the entire firm, the sum of the two pools, is constant regardless of the debt ratio. Thus,

$$r_1^* = r_{A1} \qquad \text{(E-1a)}$$

where r^*_1 is the overall after-tax cost of capital at any particular capital structure and r_{A1} is the all-equity cost of capital for the firm. (The "1" subscripts distinguish the case where there are no taxes from subsequent equations that consider first corporate and then both corporate and personal taxes.) With no taxes and no risk to debt, the overall cost of capital does not change with capital structure.

This implies that the relationship of the overall cost of capital to the component costs of debt and equity is

[1] Franco Modigliani and Merton H. Miller (1958), "The Cost of Capital, Corporation Finance and the Theory of Investment," *American Economic Review*, 48, pp. 261-297.

$$r_{E1} \times \left(\frac{E}{V}\right) + r_{D1} \times \left(\frac{D}{V}\right) = r_1^* \qquad \text{(E-1b)}$$

with the overall cost of capital (r^*) on the *right* side, as the *independent* variable, and the costs of equity (r_E) and debt (r_D) on the left side, as *dependent* variables determined by the overall cost of capital and by the capital structure (i.e., the shares of equity (E) and debt (D) in overall firm value (V=E+D)) that the firm happens to choose. Note that if equation (E-1a) were correct, the equation that solved it for the cost of equity would be,

$$r_{E1} = r_1^* + (r_1^* - r_D) \times \left(\frac{D}{E}\right) \qquad \text{(E-1c)}$$

Note also that (D/E) gets exponentially higher in this equation as the debt-to-value ratio increases[2] i.e., the cost of equity increases exponentially with leverage.

2. Corporate Tax Deduction for Interest Expense

Q6. What happens when you add corporate taxes to the discussion?

A6. If corporate taxes exist with risk-free debt (and if only taxes at the corporate level matter, not taxes at the level of the investor's personal tax return), the initial conclusion changes. Debt at the corporate level reduces the company's tax liability by an amount equal to the marginal tax rate times interest expense. All else equal, this will add value to the company because more of the operating cash flows will end up in the hands of investors as a group. That is, if only corporate taxes mattered, interest would add cash to the firm equal to the corporate tax rate times the interest expense. This increase in cash would increase the value of the firm, all else equal. In cost of capital terms, it would reduce the overall cost of capital.

How much the value of the firm would rise and *how far* the overall cost of capital would fall would depend in part on how often the company adjusts its capital structure, but this is a second-order effect in practice. (The biggest effect would be if companies could issue riskless perpetual debt, an assumption Profs. Modigliani and Miller explored in

[2] For example, at 20-80, 50-50, and 80-20 debt-equity ratios, (D/E) equals, respectively, (20/80) = 0.25, (50/50) = 1.0, and (80/20) = 4.0. The extra 30 percent of debt going from 20-80 to 50-50 has much less impact on (D/E) [i.e., by moving it from 0.25 to 1.0] than the extra 30 percent of debt going from 50-50 to 80-20 [i.e., by moving it from 1.0 to 4.0]. Since the cost of equity equals a constant risk premium times the debt-equity ratio, the cost of equity grows ever more rapidly as you add more and more debt.

1963, in the second seminal paper;[3] this assumption could *not* be true for a real company.) Prof. Robert A. Taggart provides a unified treatment of the main papers in this literature and shows how various cases relate to one another.[4] Perhaps the most useful set of benchmark equations for the case where only corporate taxes matter are:

$$r_2^* = r_{A2} - r_D \times t_C \times \left(\frac{D}{V}\right) \quad \text{(E-2a)}$$

$$r_2^* = r_{E2} \times \left(\frac{E}{V}\right) + r_D \times \left(\frac{D}{V}\right) \times (1 - t_C) \quad \text{(E-2b)}$$

which imply for the cost of equity,

$$r_{E2} = r_{A2} + (r_{A2} - r_D) \times \left(\frac{D}{E}\right) \quad \text{(E-2c)}$$

where the variables have the same meaning as before but the "2" subscripts indicate the case that considers corporate but not personal taxes.

Note that Equation (E-2a) implies that when only corporate taxes matter, the overall after-tax cost of capital declines steadily as more debt is added, until it reaches a minimum at 100 percent debt (i.e., when D/V = 1.0). Note also that Equation (E-2c) still implies an exponentially increasing cost of equity as more and more debt is added. In fact, except for the subscript, Equation (E-2c) looks just like Equation (E-1c).

However, whether any value is added and whether the cost of capital changes at all also depends on the effect of taxes at the personal level.

3. Personal Tax Burden on Interest Expense

Q7. How do personal taxes affect the results?

A7. Ultimately, the purpose of investment is to provide income for consumption, so personal taxes affect investment returns. For example, in the U.S., municipal bonds have lower interest rates than corporate bonds because their income is taxed less heavily at the

[3] Franco Modigliani and Merton H. Miller (1963), "Corporate Income Taxes and the Cost of Capital: A Correction," *American Economic Review*, 53, pp. 433-443.

[4] Robert A. Taggart, Jr. (1991), "Consistent Valuation and Cost of Capital Expressions with Corporate and Personal Taxes," *Financial Management* 20, pp. 8-20.

personal level. In general, capital appreciation on common stocks is taxed less heavily than interest on corporate bonds because (1) taxes on unrealized capital gains are deferred until the gains are realized, and (2) the capital gains tax rate is lower. Dividends are taxed less heavily than interest, also, under current tax law.[5] The effects of personal taxes on the cost of common equity are hard to measure, however, because common equity is so risky.

Professor Miller, in his Presidential Address to the American Finance Association,[6] explored the issue of how personal taxes affect the overall cost of capital. The paper pointed out that personal tax effects could offset the effect of corporate taxes entirely.

Q8. Is it likely that the effect of personal taxes will completely neutralize the effect of corporate taxes?

A8. I do not believe so, although the likelihood of such a result would be increased if the current federal tax reductions on dividends and capital gains became permanent rather than expiring in 2010. However, personal taxes are important even if they do not make the corporate tax advantage on interest vanish entirely. Capital gains and dividend tax advantages definitely convey some personal tax advantage to equity, and even a partial personal advantage to equity reduces the corporate advantage to debt.

The Taggart paper explores the case of a partial offset, also. With personal taxes, the risk-free rate on the security market line is the after-personal-tax rate, which must be equal for risk-free debt and risk-free equity.[7] Therefore, the pre-personal-tax risk-free rate for equity will generally not be equal to the pre-personal-tax risk-free rate for debt. In particular, $r_{fE} = r_{fD} \times [(1-t_D)/(1-t_E)]$, where r_{fE} and r_{fD} are the risk-free costs of equity and debt and t_E and t_D are the personal tax rates for equity and debt, respectively. In

[5] The current maximum personal tax rate on dividend income was extended to the end of 2010 by the President on May 17, 2006. It is uncertain whether the reduced rates on dividend income will be further extended.

[6] Merton H. Miller (1977), "Debt and Taxes," *The Journal of Finance*, 32: 261-276, the third of the seminal papers mentioned earlier.

[7] As Prof. Taggart notes (his footnote 9), it is not necessary that a specific, risk-free equity security exist as long as one can be created synthetically, through a combination of long and short sales of traded assets. Such constructs are a common analytical tool in financial economics.

terms of the cost of debt, the Taggart paper's results imply that a formal statement of these effects can be written as:[8]

$$r_3^* = r_{A3} - r_D \times t_N \times \left(\frac{D}{V}\right) \tag{E-3a}$$

$$= r_{E3} \times \left(\frac{E}{V}\right) + r_D \times \left(\frac{D}{V}\right) \times (1 - t_C) \tag{E-3b}$$

which imply

$$r_{E3} = r_{A3} + \left[r_{A3} - r_D \times \left(\frac{1-t_D}{1-t_E}\right)\right] \times \left(\frac{D}{E}\right) \tag{E-3c}$$

Suppose, for example, that t_C = 0.35 percent, t_E = 7.7 percent and t_D = 40 percent. Then $[(1-t_D)/(1-t_E)]$ = 0.65 = $(1-t_C)$. That condition corresponds to Miller's 1977 paper, in which the net personal tax advantage of equity fully offsets the net corporate tax advantage of debt. Note also that in that case, t_N = 0.[9] Therefore, if the personal tax advantage on equity fully offsets the corporate tax advantage on debt, Equation (E-3a) confirms that the overall after-tax cost of capital is a constant.

However, it is unlikely that the personal tax advantage of equity fully offsets the corporate tax advantage of debt. If taxes were all that mattered (i.e., if there were no other costs to debt), the overall after-corporate-tax cost of capital would still fall as debt was added, just not as fast.

Finally, note that the overall after-tax cost of capital, Equation (E-3b), still uses the corporate tax rate even when personal taxes matter. Equations (E-2b) and (E-3b) both correspond to the usual formula for the ATWACC. Personal taxes affect the way the cost of equity changes with capital structure -- Equation (E-3c) -- but not the formula for the overall after-tax cost of capital given that cost of equity.

---

[8] The net all-tax effect of debt on the overall cost of capital, t_N, equals $\{[t_C+t_E-t_D-(t_C \times t_E)] / (1-t_E)\}$, where t_D is the personal tax rate on debt, as before. This measure of net tax effect is designed for use with the cost of debt in Equation (E-3a), which seems more useful in the present context. The Taggart paper works with a similar measure, but one which is designed for use with the cost of risk-free equity in the equivalent Taggart equation.

[9] In the above example, $t_N = \{[0.35+0.077-0.4-(0.35 \times 0.077)] / (1.0-0.077)\} = 0.0/0.923 = 0$.

B. NON-TAX EFFECTS

Q9. Please describe the non-tax effects of Debt.

A9. If debt is truly valuable, firms should use as much as possible, and competition should drive firms in a particular industry to the same, optimal capital structure for the industry. If debt is harmful on balance, firms should avoid it. Neither picture corresponds to what we actually see. A large economic literature has evolved to try to explain why.

Part of the answer clearly is the costs of excessive debt. Here the results cannot be reduced to equations, but they are no less real for that fact. As companies add too much debt, the costs come to outweigh the benefits. Too much debt reduces or eliminates financial flexibility, which cuts the firm's ability to take advantage of unexpected opportunities or weather unexpected difficulty. Use of debt rather than internal financing may be taken as a negative signal by the market.

Even if the company is generally healthy, more debt increases the risk that the company cannot use all of the interest tax shields in a bad year. As debt continues to grow, this problem grows and others may crop up. Management begins to worry about meeting debt payments instead of making good operating decisions. Suppliers are less willing to extend trade credit, and a liquidity shortage can translate into lower operating profits. Ultimately, the firm might have to go through the costs of bankruptcy and reorganization. Collectively, such factors are known as the costs of "financial distress."[10]

The net tax advantage to debt, if positive, is affected by costs such as a growing risk that the firm might have to bear the costs of financial distress. First, the expected present value of these costs offsets the value added by the interest tax shield. Second, since the likelihood of financial distress is greater in bad times when other investments also do poorly, the possibility of financial distress will increase the risks investors bear. These effects increase the variability of the value of the firm. Thus, firms that use too much debt can end up with a higher overall cost of capital than those that use none.

[10] See, for example, Section 18.3 of Brealey, Myers and Allen, 2006, *Principles of Corporate Finance*, 8th Edition, McGraw-Hill/Irwin, 2006.

Other parts of the answer include the signals companies send to investors by the decision to issue new securities, and by the type of securities they issue. Other threads of the literature explore cases where management acts against shareholder interests, or where management attempts to "time" the market by issuing specific securities under different conditions. For present purposes, the important point is that no theory, whether based on taxes or on some completely different issue, has emerged as "the" explanation for capital structure decisions by firms. Nonetheless, despite the lack of a single "best" theory, there is a great deal of relevant empirical research.

Q10. What does that research show?

A10. The research does not support the view that debt makes a material difference in the value of the firm, at least not once a modest amount of debt is in place. If debt were truly valuable, competitive firms should use as much debt as possible short of producing financial distress, and competitive firms that use less debt ought to be less profitable. The research shows exactly the opposite.

For example, Kester[11] found that firms in the same industry in both the U.S. and Japan do not band around a single, "optimal" capital structure, and the most profitable firms are the ones that use the *least* debt. This finding comes despite the fact that both countries at the time (unlike the U.S. currently) had fully "classical" tax systems, in which dividends are taxed fully at both the corporate and personal level. Wald[12] confirms that high profitability implies low debt ratios in France, Germany, Japan, the U.K., and the U.S. Booth *et al.* find the same result for a sample of developing nations.[13] Fama and French[14] analyze over 2000 firms for 28 years (1965-1992, inclusive) and conclude, "Our tests

[12] John K. Wald (1999), "How Firm Characteristics Affect Capital Structure: An International Comparison," *Journal of Financial Research*, 22:161-167.

[13] Laurence Booth *et al.* (2001), "Capital Structures in Developing Countries," *The Journal of Finance* Vol. LVI, pp. 87-130, finds at p. 105 that "[o]verall, the strongest result is that profitable firms use less total debt. The strength of this result is striking ..."

[14] Eugene F. Fama and Kenneth R. French (1998), "Taxes, Financing Decisions and Firm Value," *The Journal of Finance*, 53:819-843.

thus produce no indication that debt has net tax benefits."[15] A paper by Graham[16] carefully analyzes the factors that might have led a firm not to take advantage of debt. It confirms that a large proportion of firms that ought to benefit substantially from use of additional debt, including large, profitable, liquid firms, appear not to use it "enough."

This research leaves us with only three options: either (1) apparently good, profit-generating managers are making major mistakes or deliberately acting against shareholder interests, (2) the benefits of the tax deduction on debt are less than they appear, or (3) the non-tax costs to use of debt offset the potential tax benefits. Only the first of these possibilities is consistent with the view that the tax deductibility of debt conveys a material cost advantage. Moreover, if the first explanation were interpreted to mean that otherwise good managers are acting against shareholder interests, either deliberately or by mistake, it would require the additional assumption that their competitors (and potential acquirers) let them get away with it.

Q11. Are there any explanations in the financial literature for this puzzle other than stupid or self-serving managers at the most profitable firms?

A11. Yes. For example, Stewart C. Myers, a leading expert on capital structure, made it the topic of his Presidential Address to the American Finance Association.[17] The poor performance of tax-based explanations for capital structure led him to propose an entirely different mechanism, the "pecking order" hypothesis. This hypothesis holds that the net tax benefits of debt (i.e., corporate tax advantage over personal tax disadvantage) are at most of a second order of importance relative to other factors that drive actual debt decisions.[18] Similarly, Baker and Wurgler (2002)[19] observe a strong and persistent

[18] See also Stewart C. Myers (1989), "Still Searching for Optimal Capital Structure," *Are the Distinctions Between Debt and Equity Disappearing?,* R.W. Kopke and E. S. Rosengren, eds., Federal Reserve Bank of Boston.

[19] Malcolm Baker and Jeffrey Wurgler (2002), "Market Timing and Capital Structure," *The Journal of Finance* 57:1-32.

impact that fluctuations in market value have on capital structure. They argue that this impact is not consistent with other theories. The authors suggest a new capital structure theory based on market timing -- capital structure is the cumulative outcome of attempts to time the equity market.[20] In this theory, there is no optimal capital structure, so market timing financing decisions just accumulate over time into the capital structure outcome. (Of course, this theory only makes sense if investors do not recognize what managers are doing.)

Q12. Do inter-firm differences within an industry explain the wide variations in capital structure across the firms in an industry?

A12. No. This view is contradicted by the empirical research. As mentioned before, it has long been found that the most profitable firms in an industry, i.e., those in the best position to take advantage of debt, use the least.[21] Graham (2000) carefully examines differences in firm characteristics as possible explanations for why firms use "too little" debt and concludes that such differences are *not* the explanation: firms that ought to benefit substantially from more debt by all measurable criteria, if the net tax advantage of debt is truly valuable, voluntarily do not use it.[22]

Nor does the research support the view that firms are constantly trying to adjust their capital structures to optimal levels. Additional research on the pecking order hypothesis demonstrates that firms do not tend towards a target capital structure, or at least do not do so with any regularity, and that past studies that seemed to show the contrary actually lacked the power to distinguish whether the hypothesis was true or not.[23] In the words of

---

[20] *Ibid.*, p. 29.

[21] For example, Kester, *op. cit.* and Wald, *op. cit.*

[22] While not contradicting Graham's finding that differences in firm characteristics do not explain capital structure differences, Nengjiu Ju, Robert Parrino, Allen M. Poteshman, and Michael S. Weisbach, "Horses and Rabbits? Trade-Off Theory and Optimal Capital Structure," *Journal of Financial and Quantitative Analysis*, June 2005, pp. 1-24, looks at the issue in a different manner. Their paper uses a dynamic rather than static model to analyze the tradeoff between the tax benefits of debt and the risk of financial distress. It finds that bankruptcy costs by themselves are enough to explain observed capital structures, once dynamic effects are considered. This means debt is not as valuable as suggested by the traditional static analysis (of the sort used by Graham).

[23] Lakshmi Shyam-Sunder and Stewart C. Myers (1999), "Testing static tradeoff against pecking order models of capital structure," *Journal of Financial Economics* 51:219-244.

the Shyam-Sunder - Myers paper p. 242, "If our sample companies did have well-defined optimal debt ratios, it seems that their managers were not much interested in getting there."

II. EXPANDED EXAMPLE

Q13. What topics do you cover in this section?

A13. The discussion in my testimony did not detail the impact of different starting points for the level of debt nor did it address income earned on the investment, interest expense, or taxes. This section covers these topics. First, it discusses how the level of debt affects the cost of equity. Second, it addresses the influence of income and interest on the investment. Third, it explains the impact of taxes on capital structure decisions. The final topic covered in this section is the combined consequence of tax and non-tax effects of debt.

A. DETAILS OF DIFFERENT LEVELS OF DEBT

Q14. Why does more debt mean more risk for equity holders?

A14. Debt magnifies the variability of the equity return. As a simple example, think of an investor who takes money out of her savings and invests $100,000 in real estate. The future value of the real estate is uncertain. If the real estate market booms, she wins. If the real estate market goes down, she loses. Figure E-1 below illustrates this.

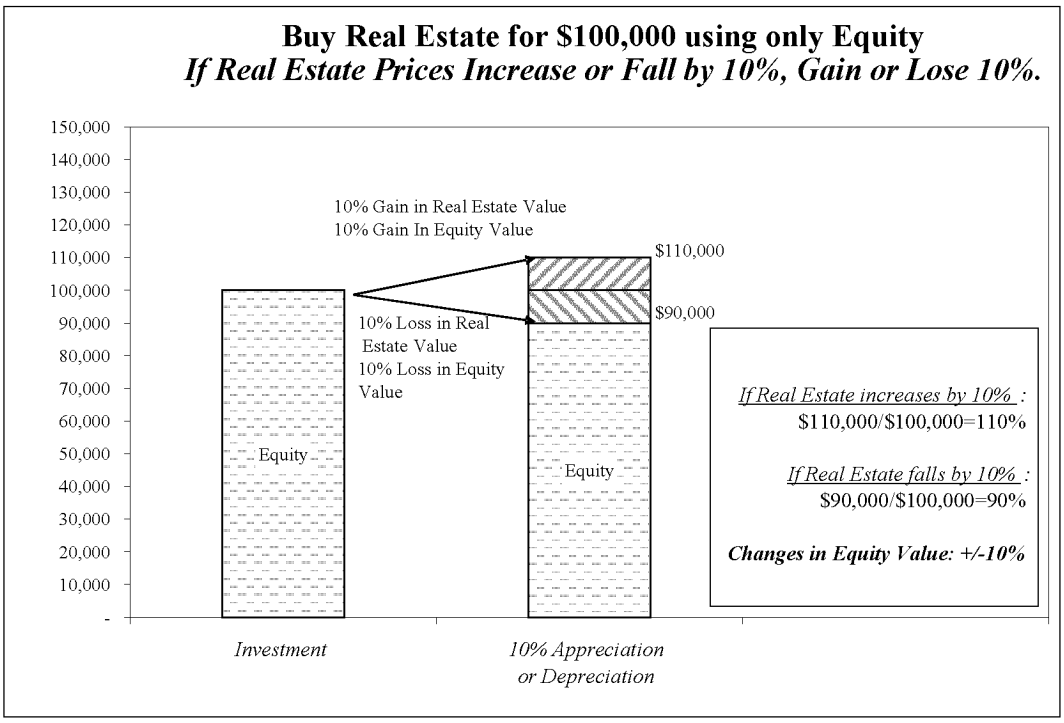

Figure E-1

In the scenario above, the investor financed her real estate purchase through 100 percent equity. Suppose instead that the investor had financed 50 percent of her real estate investment with a mortgage of $50,000. The mortgage lender does not expect to share in any benefits from increases in real estate values. Neither does the mortgage lender expect to share in any losses from falling real estate values, i.e., the investor carries the entire risk of fluctuating real estate prices. Figure E-2 illustrates this effect.

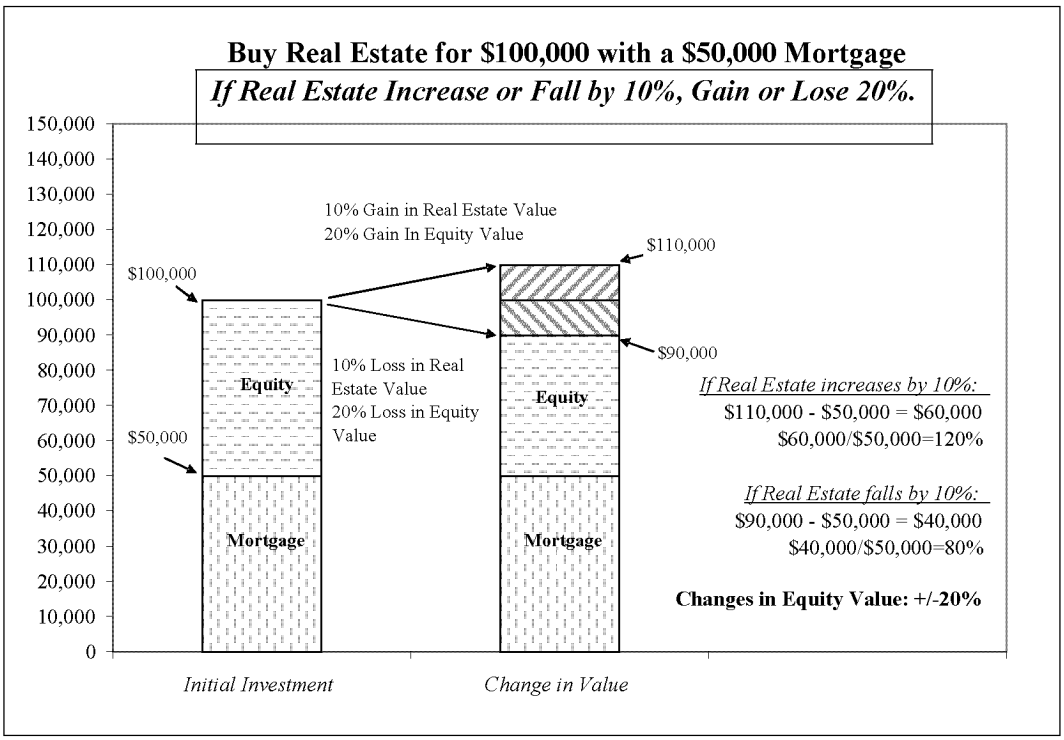

Figure E-2

In Figure E-2 where the investor financed her purchase through 50 percent equity and 50 percent debt, the variability in the investor's equity return is two times greater than that of Figure E-1. The entire fluctuation of 10 percent from rising or falling real estate prices falls on the investor's $50,000 equity investment. The lesson from the example is obvious, debt adds risk to equity.

Q15. What happens if the investor finances the real estate purchase with different proportions of debt?

A15. The equity return becomes more variable when the mortgage percentage is a greater proportion of the initial price. Table E-1 below calculates the return on equity when real estate prices increase by 10 percent when mortgages are 0 percent, 30 percent, 50 percent, and 70 percent of the initial price.

Table E-1: The Impact of Leverage on the Return on Equity

	100% Equity	70% Equity	50% Equity	30% Equity
Debt	$0	$30,000	$50,000	$70,000
Original Equity Investment	$100,000	$70,000	$50,000	$30,000
Increase in Market Value of Equity	$10,000	$10,000	$10,000	$10,000
Return on Equity Investment	10%	14.3%	20%	33.3%

Note that going from 70 percent equity down to 50 percent equity increases the return on the equity investment by 5.7 percent while going from 50 percent equity to 30 percent equity increases the return on equity by 13.3 percent. This illustrates a general point; the rate of return on equity increases more quickly at higher levels of debt than at lower levels. Investors demand a higher equity rate of return to bear more risk and debt magnifies equity's risk at an ever increasing rate. Therefore, the required equity rate of return goes up at an ever increasing rate as debt is added. This is not only basic finance theory, it is the everyday experience of anyone who buys a home. The bigger the mortgage, the more percentage risk the equity faces from changes in housing prices.

Q16. Please provide an example that illustrates why market values are relevant.

A16. Suppose in the above example that the investor has invested in real estate 10 years ago. Further assume that depreciation has reduced the book value of the real estate from $100,000 to $75,000 and assume the investor has paid off 40 percent of his $50,000 mortgage. Thus, the investor has a remaining mortgage of $30,000 (= 60% × $50,000). The book value of the investor's equity investment is therefore $45,000 (= $75,000 - $30,000).

What happens now if real estate prices rise or fall 20 percent? To answer that question, we need to know how real estate prices have developed over the past 10 years. If the market value of the real estate now is $200,000 then a 20 percent decrease in the price of real estate ($40,000) is almost equal to the investor's book value equity. However, his

market value equity (or net worth) is equal to the value of the real estate minus what he owes on the mortgage. If we assume that the market value of the mortgage equals the unpaid balance ($30,000), then the investor's net worth is calculated as follows:

Net Worth	=	Market Value of Real Estate	-	Remaining Mortgage
	=	$200,000	-	$30,000
	=	$170,000		

Therefore, the rate of return on equity due to a 20 percent decline in real estate prices is calculated in Table E-2.

Table E-2: Calculating the Rate of Return on Equity

Decline in Real Estate Value	$40,000
Market-Value Equity	$170,000
Rate of Return on Equity	- $40,000/$170,000 = -23.5%

B. THE IMPACT OF INCOME AND INTEREST

Q17. How does earning income from the investment and paying interest on debt affect the results?

A17. In the following explanation, I ignore income taxes which I deal with in Section C below. Assume the investor is receiving income, e.g., rent, from the real estate. Specifically, assume the investor receives $500 per month in income after all non-interest expenses ($6,000 per year). Also, assume that the expected appreciation is 5 percent per year, so the expected market value is $105,000 after one year. Then the expected rate of return from the real estate with all equity financing is:

$$\text{Expected Return on Equity @ 0\% debt} = \frac{\text{Expected Net Income + Expected Appreciation}}{\text{Initial Investment}}$$

$$= \frac{\$6{,}000 + (\$105{,}000 - \$100{,}000)}{\$100{,}000}$$

$$= 11\%$$

Now suppose that the mortgage interest rate were 5 percent. Then at a mortgage equal to 50 percent, or $50,000, interest expense would be ($50,000 x 0.05), or $2,500. The expected equity rate of return would be:

$$\text{Expected Return on Equity @ 50\% debt} = \frac{\text{Expected (Net Income + Appreciation) – Int. Expense}}{\text{Initial } \textit{Equity} \text{ Investment}}$$

$$= \frac{\$6{,}000 + \$5{,}000 - \$2{,}500}{\$50{,}000}$$

$$= 17\%$$

Notice that the expected return on equity is higher as is the risk carried by equity.

Q18. Can you provide a more general illustration?

A18. Yes. Figure E-3 uses these assumptions at different mortgage levels to plot both (i) the expected rate of return on the equity in the dwelling, and (ii) the realized rate of return on

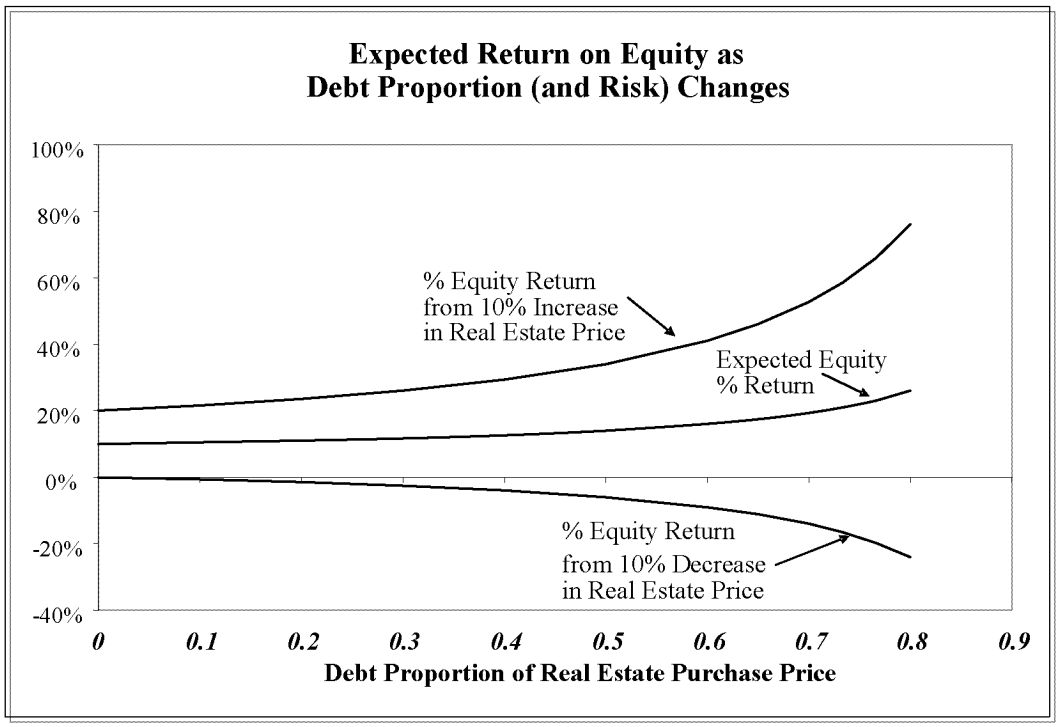

Figure E-3

that equity in a year if the dwelling value increases by 10 percent more than the expected 5 percent rate (i.e., if the value increases by 15 percent) or by 10 percent less than expected (i.e., if it decreases by 5 percent).[24]

The expected rate of return on equity increases at an increasing rate as the investor finances more and more of the real estate through loans (e.g., with a mortgage). Since equity bears all the risk of increases or decreases in real estate values (absent financial distress or bankruptcy), the amount of risk the buyer bears grows at an ever increasing rate as the mortgage percentage also increases.

Q19. What are the implications of this example?

A19. Any time an individual or a company uses debt to finance part an investment, the same risk magnifies. For example, if an investor buys stocks "on margin" -- by borrowing part of the money used to buy the stock -- the expected rate of return will be higher as will the risks the investor carries. As an everyday example, imagine investing your retirement

savings in a stock portfolio bought with as much margin as possible. If you were lucky, you could end up living very well in retirement. But you would be taking a lot of risk on the opposite outcome, since your portfolio could decline by more than 100 percent of your initial investment.

The same risk-magnifying effects happen when companies borrow to finance part of their investments.

C. THE EFFECT OF TAXES

Q20. What is the impact of taxes?

A20. Analyzing the net effect of taxes in capital structure decisions by corporations is an important part of the financial research. (Other parts of that research address such issues as the risk of financial distress or bankruptcy, and the signals corporations send investors by the choice of how to finance new investments.) The bottom line is that taxes complicate the picture without changing the basic conclusion.

Q21. Please describe the potential impact of taxes.

A21. Interest expense is tax-deductible for corporations. That increases the pool of cash the corporation gets to keep out of its operating earnings (i.e., its earnings before interest expense). With no debt, 100 percent of operating income is subject to taxes. With debt, only the equity part of the operating income is subject to taxes.

All else equal, the extra money kept from operating income increases the value of the corporation. The standard way to recognize that increase in value is to use an after-tax weighted-average cost of capital as a discount rate when valuing a company's operating cash flows.

Q22. Do personal taxes affect the value of debt, too?

A22. Yes, but in the other direction. One offset to debt's tax benefits at the corporate level is its higher tax burden at the personal level. Investors care about the money they get to

[24] For simplicity, the figure assumes the debt's interest rate is independent of the debt proportion. This might not always be true, and in general would not be true for a corporation that issued debt. However, the

keep after all taxes are paid, and while the corporation saves taxes by opting for debt over equity, individuals pay more taxes on interest than on capital gains from equity (and for now, on dividends as well).

Q23. Are there factors other than taxes matter?

A23. Absolutely, "all else" does not remain equal as more debt is added. The more debt, the more the non-tax effects of debt offset the tax benefits. Other costs include such effects as a loss of flexibility, the possibility of sending negative signals to investors, and a host of costs and risks associated with the danger of financial distress.

Q24. Does the tradeoff between the tax and non-tax effects of debt mean that firms have well-defined, optimal capital structures?

A24. No, this sort of "tradeoff" model does not explain actual corporate behavior. A substantial body of economic research confirms that real-world corporations act as if, after a moderate amount of debt is in place, the tax benefits of debt are not worth debt's other costs. In country after country and in industry after industry, the most profitable corporations in an industry tend to use the least debt. The research on this point is quite thorough, and the finding that the most profitable companies tend to use the least debt in a given industry is robust. Yet these are the companies with the most operating income to shield from taxes, who would benefit most if interest tax shields were truly valuable net of debt's other costs. They also presumptively are the best-managed on average (else why are they the most profitable?). This means it is unrealistic to suppose that more debt is always better, or that greater tax savings due to higher interest expense always add value to the firm on balance.

Q25. If the tradeoff model doesn't explain capital structure decisions by firms, is there a model that does?

A25. No single model has (yet) emerged as 'the" explanation of capital structure. However, several alternative models attempt to model the tradeoff (e.g., the "pecking order" hypothesis and "agency cost" explanations).

---

general shape of the graphs remains the same.

Q26. What does the absence of an agreed theory of capital structure in the financial literature imply about the overall effect of debt on the value of the firm?

A26. The findings of the financial literature mean that within an industry, there is no well-defined optimal capital structure. The use of some debt does convey some value advantage in most industries, but that advantage is offset by other costs as firms add more debt.[25] The range of capital structures over which the value of the firm in any industry is maximized is wide and should be treated as flat. The location and level of that range, however, does vary from industry to industry, just as the overall cost of capital varies from industry to industry.

Figure E-4 illustrates the picture that emerges from the research. This figure shows the present value of an investment in each of four different industries. For simplicity, the investment is expected to yield $1.00 per year forever. For firms in relatively high-risk industries (Industry 1 in the graph, the lowest line), the $1.00 perpetuity is not worth much and any use of debt decreases firm value. For firms in relatively low-risk industries (Industry 4 in the graph), the perpetuity is worth more and substantial amounts of debt make sense. Industries 2 and 3 are intermediate cases.

The maximum net rate at which taxes can increase value in this figure equals 20 percent of interest expense, representing a balance between the corporate tax advantage to debt and the personal tax disadvantage. The figure plots the maximum possible impact of taxes on value as a separate line, starting at the all-equity value of the lowest-risk industry (Industry 4).

[25] Note that if debt did increase the value of the firm materially, competition would tend to take that value away, since issuing debt is an easy-to-copy competitive strategy. Prices would fall as firms copied the strategy, lowering operating earnings and passing the net tax advantages to debt through to customers (just as happens under rate regulation). Therefore, if also there were a narrow range of optimal capital structures within an industry, competition would drive all firms in the industry to capital structures within that range. This does not happen in practice, which contradicts one or both of the assumptions, i.e., (1) that debt adds material value on balance, and/or (2) that there is a narrow range of optimal capital structures.

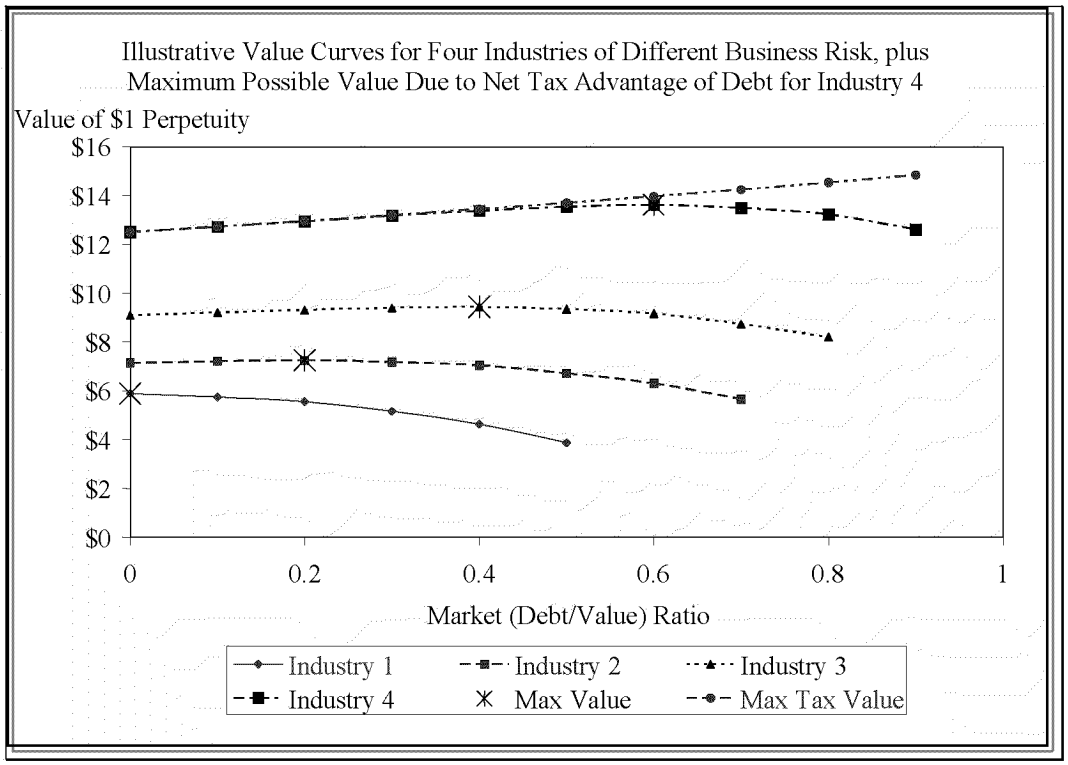

Figure E-4

Figure E-4 identifies a particular point as the maximum value on each of the four curves. However, the research shows that reliable identification of this maximum point, except in the extreme case where no debt should be used, is impossible. In accord with the research, the graph is prepared so that in none of the industries does a change in capital structure make much difference near the top of the curve. Even Industry 4, which increases in value at the maximum rate as quite a lot of debt is added, eventually must reach a broad range where changes in the debt ratio make little difference to firm value, given the research. For Industry 4, debt makes less than a 2 percent difference in the total value of the firm for debt-to-value ratios between 40 and 70 percent. (While these particular values are illustrative, numbers of this order of magnitude are the only ones consistent with the research.)

Q27. What does this imply for the overall cost of capital?

A27. Figure E-5 plots the after-tax weighted-average costs of capital ("ATWACCs") that correspond to the value curves in Figure E-4. This picture just turns Figure E-4 upside

down.[26] All the same conclusions remain, except that they are stated in terms of the overall cost of capital instead of the overall firm value. In particular, except for high-risk industries, the overall cost of capital is essentially flat across a broad middle range of capital structures for each industry, which is the only outcome consistent with the research. For Industry 4, for example, the ATWACC changes by less than 15 basis points for debt-to-value ratios between 40 and 70 percent.

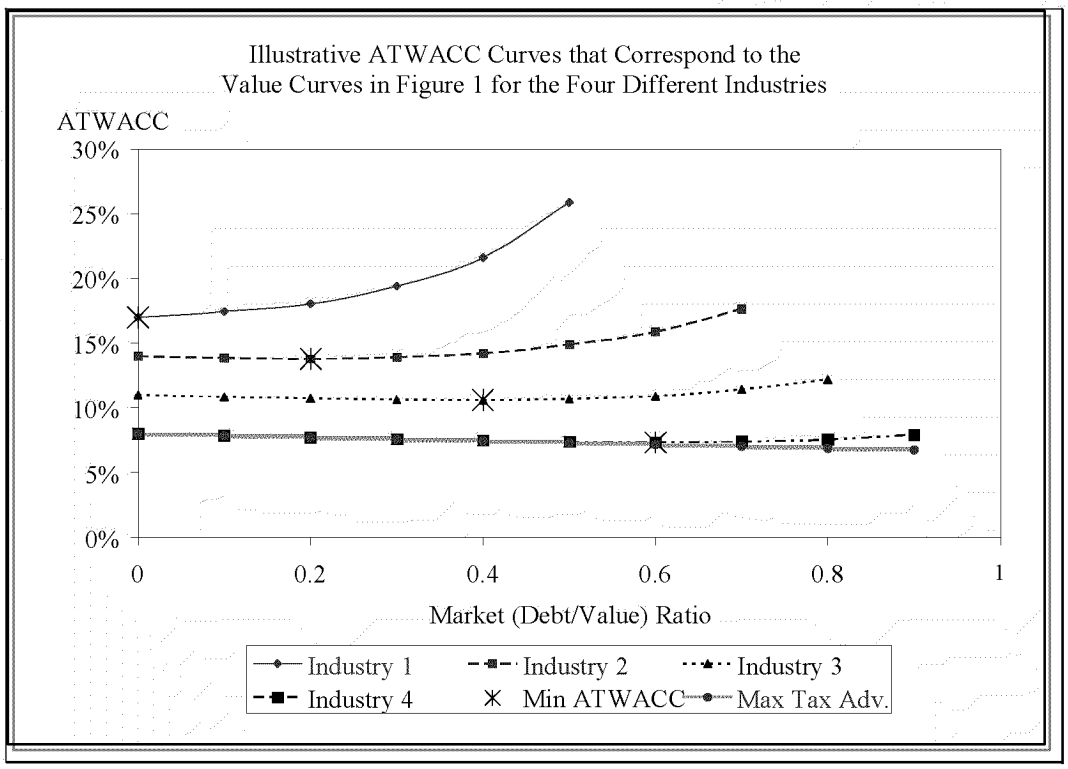

Figure E-5

Q28. How does this discussion relate to estimation of the right cost of equity for ratemaking purposes?

A28. When an analyst estimates the cost of equity for a sample of companies, s/he does so at the sample's actual market-value capital structure. That is, the sample evidence corresponds to ATWACCs that are already out somewhere in the broad middle range in

[26] Note that the actual estimated ATWACC at higher debt ratios will tend to underestimate the ATWACC that corresponds to the value curves in Figure E-4, which are depicted in Figure E-5, and so will tend to overestimate the value of debt to the firm. The reason is that some of the non-tax effects of excessive debt, such as a loss of financial flexibility, may be hard to detect and not show up in cost of capital measurement.

which changes in the debt ratio have little or no impact on the overall value of the firm or the ATWACC.

An analyst therefore should assume the ATWACCs for the sample companies are literally flat. This assumption always provides the exact tradeoff between the cost of equity and capital structure at the literal minimum of the company's ATWACC curve. The research shows that this minimum is actually a broad, flat region, as depicted above. If the company happens to be somewhat to one side or the other of the literal minimum within this region, the recommended procedure may lead to a small understatement or overstatement of the amount that the cost of equity will change as capital structure changes. The degree of this under- or overstatement, however, is very small compared to the inherent uncertainty in estimating the cost of equity in the first place. Otherwise, the financial research would have found very different results about the existence of a narrowly defined optimal capital structure.

D. COMBINED EFFECTS

Q29. Please summarize the implications for the combined impact of the tax and non-tax effects of debt.

A29. The most profitable firms do not behave as if the precise amount of debt they use makes any material difference to value, and competition does not force them into an alternative decision, as it would if debt were genuinely valuable. The explanation that fits the facts and the research is that within an industry, there is no well-defined optimal capital structure. Use of some debt does convey an advantage in most industries, but that advantage is offset by other costs as firms add more debt. The range of capital structures over which the value of the firm in any industry is maximized is wide and should be treated as flat. The location and level of that range, however, does vary from industry to industry, just as the overall cost of capital varies from industry to industry. To conclude that more debt does add more value, once the firm is somewhere in the normal range for the industry, is to conclude that corporate management in general is either blind to an easy source of value or otherwise incompetent (and that their competitors let them get away with it).

The finding that there is no narrowly defined optimal capital structure implies that analysts should estimate the ATWACCs for a sample of companies in a given industry and treat the average ATWACC value as independent of capital structure (at least within a broad middle range of capital structures). The right cost of equity for a rate-regulated company in the same industry is the number that yields the same ATWACC at the capital structure used to set the revenue requirement, since that is the cost of equity that (estimation problems aside) the sample companies would have had if their market-value capital structures had been equal to the regulatory capital structure.

I. INTRODUCTION AND SUMMARY

Q1. Please state your name and address for the record.

A1. My name is Michael J. Vilbert. My business address is The Brattle Group, 44 Brattle Street, Cambridge, MA 02138, USA.

Q2. Did you previously file testimony in this proceeding?

A2. Yes, I filed Direct Testimony ("Vilbert Direct") on behalf of Ohio Edison Company ("OE"), The Cleveland Electric Illuminating Company ("CEI") and The Toledo Electric Company ("TE"), (collectively, the "Companies" or the Ohio Electric Distribution Utilities ("Ohio EDUs")) in June 2007 regarding the return on equity that the Ohio EDUs should be allowed an opportunity to earn on the equity financed portion of their rate bases. For my professional qualifications, please see the detailed resume attached to my Direct Testimony.

Q3. What is the purpose of your supplemental testimony?

A3. I have been asked by the Companies to provide supplemental testimony that responds to the Staff of the Public Utilities Commission of Ohio's Report ("Staff Report") regarding the rate of return findings.[1] Specifically, I address the Companies' Objections III.1, III.5, III.6, III.7, III.8, III.9, III.10, and III.11. Unless otherwise indicated, my testimony applies to each of the Staff Reports on behalf of all of the Companies.

Q4. Please summarize your supplemental testimony.

A4. This supplemental testimony first addresses the importance of taking financial risk into consideration. The Staff Report underestimates the cost of equity for the Ohio EDUs because it ignores the fact that the Ohio EDUs are more leveraged, i.e., have more financial risk, than the comparable companies used in the Staff Report. Second, the Staff Report suggests relying on the consolidated capital structure of FirstEnergy rather than the capital structures of the Ohio EDUs. This again underestimates the cost of equity for

[1] A Report by the Staff of the Public Utilities Commission of Ohio, FirstEnergy Cleveland Electric Illuminating Company, dated December 4, 2007; A Report by the Staff of the Public Utilities Commission of Ohio, FirstEnergy Ohio Edison Company, dated December 4, 2007, and A Report by the Staff of the Public Utilities Commission of Ohio, FirstEnergy Toledo Edison company, dated December 4, 2007 (jointly "Staff Report").

the Ohio EDUs unless an adjustment is made for differences in capital structure. Third, some of the Staff Report's comparable companies also have significantly different business risks (they are engaged in oil and gas exploration rather than utility activities) and substantially different capital structures. Further, the Staff Report eliminates companies with beta estimates above 1.0 from consideration, which leads to a bias in the sample selection. Specifically, comparable companies should be selected based on their inherent business risk characteristics not based on parameters that are a consequence of the underlying business risk in combination with financial leverage. Two companies with the identical business risk from their operations can have very different betas for their equity claims. Fourth, the Staff Report's implementation of its cost of equity estimation models is problematic. Finally, and importantly, the Staff Report "has explicitly *not* considered any additional risk factors relating to provision of electric generation service ..."[2] Because the pending legislation in Ohio may substantially change the competitive landscape in the state[3] for the already de-regulated Ohio EDUs, failing to analyze additional risk factors leads to an underestimation in the cost of equity for the Ohio EDUs. Specifically, the uncertainty about the final form of the legislation and its impact on the Companies' ability to fully recover all costs from the Standard Service Offer ("SSO") imposes additional risks on the Companies and its investors.

II. FINANCIAL RISK AND CAPITAL STRUCTURE

Q5. What does this section of your supplemental testimony address?

A5. This section, which addresses Companies' Objection III.7, first discusses financial risk and how it is properly measured by reference to a company's market value capital structure, not its book value capital structure. It then explains how the ATWACC approach addresses the issue of differences in financial risk among the sample companies and relative to the Ohio EDUs. In Section B, it discusses the capital structure of the Ohio EDUs and explains the treatment of the Ohio EDUs under the stand-alone principle.

[2] Staff Report; Cleveland Electric Illuminating Company, p. 16. The identical statement appears in the other two Staff Reports.

[3] See, for example, Ohio SSB 221: Deregulation, Regulation and Creditworthiness, December 14, 2007.

A. FINANCIAL RISK IS IMPORTANT

Q6. Please define financial risk.

A6. Recall that business risk is the risk of a company's assets if the company used no debt to finance the assets. Financial risk is the additional risk imposed on equity holders from the use of debt when a company finances its assets. Changing a company's capital structure by replacing equity with debt increases the risk that remaining equity holders bear. This is because debt holders are paid a fixed payment stream first before any payments are available to equity holders, but the total risk of the underlying assets is unchanged by the refinancing. As the percentage of equity in the capital structure shrinks, more of the residual risk is left to be shouldered by a smaller equity base.[4] (The interaction of capital structure and financial risk are discussed in my direct testimony in Section II.B and C.)

Q7. Did the Staff Report consider financial risk?

A7. No. The Staff Report submitted on December 4, 2007 did not discuss the difference in financial risk between the comparable companies and the Ohio EDUs nor did the Staff Report take financial risk into consideration in arriving at its cost of equity estimates. Because the Staff Report's sample companies have substantially higher equity percentages in their capital structures on average than do the Ohio EDUs, ignoring the differences in leverage between the comparable companies and the Ohio EDUs substantially underestimates the cost of equity for the Ohio EDUs.

Q8. Why is consideration of financial risk important?

A8. If differences in financial risk are not considered, the rate of return allowed for the regulated company may not fully compensate equity holders for the risks that they in fact face. For example, two otherwise identical companies with different capital structures will have different costs of equity.

Q9. How did the Vilbert Direct take financial risk into account?

A9. In my direct testimony in Section II.C, I used the ATWACC approach to compensate for differences in financial risk. The fundamental premise of the ATWACC approach is that

[4] Vilbert Direct, p.4.

the risk of the assets of a company is divided between the debt holders and equity holders, *i.e.*, the company's investors.[5] This reflects perhaps the most basic and fundamental concept in corporate finance theory and practice. When estimating the cost of equity using standard models, the estimated cost of equity reflects *both* the business risk and the financial risk of the sample company, based upon the sample company's *market value* capital structures. In particular, note that if the market value capital structures were different, the estimated cost of equity would be different as well because of the differences in financial risk.

The ATWACC approach takes the effect of capital structure into account and allows computation of the market cost of equity for any capital structure within a broad range.[6] The details of this approach are discussed in Section II.C of my direct testimony, but briefly the ATWACC approach estimates the overall weighted-average cost of capital of the sample companies. The overall cost of capital estimate captures the market cost of the underlying business risk in a single number. Unlike the cost of equity which varies with capital structure, even for otherwise identical companies, the overall cost of capital does not. If a firm with 60 percent equity and an 8 percent overall cost of capital were to refinance itself into a firm with 50 percent equity instead, leaving assets unchanged, then its cost of equity would rise, but the overall cost of capital would stay at 8 percent. This approach therefore enables an "apples to apples" comparison among the sample companies with similar business risk but very different capital structures. This is why the ATWACC approach is the best way of approaching the cost of equity estimation problem – it is the only cost common to all companies of similar business risk and can therefore provide the only reliable anchor point.

B. The Relevant Capital Structure is That of the Utility

Q10. What capital structure does Staff Report suggest?

A10. Staff Report suggests

[5] Preferred equity is ignored for simplicity, but the principles do not change with the addition of preferred stock to the capital structure.

[6] That is, a capital structure that does not include extreme leveraging or very little debt.

> [s]ubstituting the parent Company's capital structure for the wholly owned subsidiary is legitimate as parent and subsidiary capital structures would be equivalent under a regimen of efficient capital budgeting, and capital costs would not be separated for each corporate entity.[7]

In other words, the Staff Report relies on the capital structure of FirstEnergy Corp. as opposed to the capital structures of the Ohio EDUs.

Q11. How do you respond to this recommendation?

A11. Entities with very similar business risks will have overall costs of capital that are the same, but efficient capital budgeting does not imply that the capital structures of the parent and subsidiary companies would be the same. In support of the Companies' Objection III.1, and as noted in the Vilbert Direct in Section II.C, the ATWACC (After Tax Weighted Average Cost of Capital) – a company's overall cost of capital -- is constant over a broad range of capital structures. However, the cost of equity is not. Therefore, it is incorrect to rely on the parent's capital structure without an adjustment for the additional risk inherent in that capital structure compared to the capital structure of the Ohio EDUs.

The consolidated capital structure of FirstEnergy reflects the choices of the parent company regarding how to finance FirstEnergy's consolidated assets which consist not only of the Ohio EDUs' regulated assets but also of non-regulated generation and other assets. Therefore, the business risks of these assets may well be different from the risks of the Ohio EDUs' assets. Consequently, a capital structure reflective of the Ohio EDUs is preferable because it more accurately reflects the decisions on how to finance the Companies' distribution assets rather than the aggregate of all of the assets of the parent and all of its subsidiaries. In addition, the required return on equity depends on the risk of the investment and not on the parent's financing costs. The cost of equity for the Companies should reflect the risk of the underlying assets and be comparable to the return that is achievable on investments of comparable risk.

[7] Staff Report, p. 15.

Q12. What about the Staff Report's reference to a "regimen of efficient capital budgeting" in the above quote? Does the Staff Report justify the use of the parent company's capital structure?

A12. No. This rationale of efficient capital budgeting only makes sense in the context of an overall cost of capital approach, i.e., the ATWACC approach. Efficient capital budgeting means that the overall rate of return for investments of comparable business risk is the same. If differences in capital structure were not considered, the overall rate of return in the comparable investments would not be the same and capital budgeting would be inefficient. In other words, the Staff Report's justification relies implicitly on a constant overall cost of capital for entities with similar business risk. Moreover, taking into account its non-regulated businesses and other operations, FirstEnergy as a whole may well face business risks that differ from just those of the Ohio EDUs. I would expect management to make discretionary, marginal investments in the Ohio EDUs and other subsidiaries based on the specific subsidiary's risk/return tradeoff taking into account the business as well as the financial risk of the entity. This makes the allowed return on equity for the Ohio EDUs a critical component of the parent company's capital budgeting analysis.

Q13. Why would it be inefficient to disregard differences in capital structure for capital budgeting purposes?

A13. Capital budgeting is the process of allocating investment funds to projects. One test of the process is to insure that the rate of return expected on the investment is equal to or greater than the risk-adjusted required return on the investments. If differences in capital structures are not considered, projects of similar risk may be incorrectly accepted or rejected. In other words, projects cannot be made more desirable by altering the capital structure used to finance the projects. If that were true, we would simply finance all projects with "cheap" debt, but of course we know that at some point we can raise no more debt. This is the standard financial theory that underlies the reference to efficient capital budgeting.[8]

[8] Thomas E. Copeland and J. Fred Weston, *Financial Theory and Corporate Policy*, Reading, Massachusetts: Addison-Wesley Publishing Company, 2nd Edition, pp. 17-45.

Q14. Have you reviewed the Staff Report's recommendation for the capital structure for Duke Energy of Ohio?

A14. Yes. The report was filed on December 20, 2007, and it seems to accept the concept inherent in the Companies' recommendation here to use a capital structure reflective of the Ohio EDUs. The Staff appears to have changed its view regarding the appropriate capital structure for a regulated, wholly-owned subsidiary of a much larger parent company. Specifically, the Staff Report for Duke Energy of Ohio says

> The Applicant, Duke Energy Ohio, is a wholly-owned subsidiary of Duke Energy Corporation which is a publicly traded, public utility holding company. The Staff used the capital structure of Duke Energy Ohio, from Applicant's D-1A, in the rate of return determination.[9]

That approach, if adopted in this proceeding, would be consistent with use of the representative capital structure of the Ohio EDUs as was filed by the Companies.

III. COMPARABLE COMPANIES MUST BE COMPARABLE

Q15. Are there any issues with the comparable companies relied upon in the Staff Report?

A15. Yes. This portion of my testimony is in support of Companies' Objection III.5. The selected "comparable" companies include companies that operate in a different industry or substantially different regulatory environment. More troublesome, however, is the choice to drop any company with a reported *Value Line* beta greater than 1.0 without any consideration of that company's characteristics while at the same time leaving in companies with relatively low betas.

Q16. How was the comparable group of companies selected in the Staff Report?

A16. According to the Staff Report and supplemented by its workpapers,[10] Staff looked at publicly traded utilities followed by *Value Line*. The comparable sample companies were selected based on several criteria including the following: (1) *Value Line* beta not above 1.0, (2) market capitalization greater than $1.5 billion, (3) retail revenue ratio greater than

[9] Staff Report, Duke Energy of Ohio, December 20, 2007, p. 13.

[10] Staff Report, Cleveland Electric Illuminating Company, p. 15 and Workpaper p. 2 of 274.

75 percent,[11] (4) pays dividends, (5) investment grade bond rating by Fitch Ratings, and (6) screening criteria pertaining to customers, customer mix, volumes sold, generated, or purchased, etc.[12]

Q17. Please explain your concerns with the Staff Report's "comparable" companies?

A17. First and foremost, companies should be selected for inclusion in the sample because they are of comparable business risk. Recall that business risk is the risk of the assets if financed entirely by equity. The Staff Report's sample includes companies from several of *Value Line's* industry groups: Natural Gas Utility (4), Electricity (16), and Natural Gas Diversified (3). Some of these companies face risks and/or regulatory circumstances that differ substantially from those of the Companies. As such, there is no reason to believe they would have a similar cost of capital. Among the sample companies are three companies: Energen Corp., National Fuel Gas Co., and Questar Corp., classified by *Value Line* as being in the Natural Gas Diversified industry. These entities own significant natural gas pipelines, exploration and production facilities which face a different regulatory environment than do electric utilities or gas distribution companies and thus differ in their business risk. This is particularly true for Energen and Questar, who report generating 85% and 80%, respectively, of their net incomes from oil and gas exploration, marketing, and other non-regulated activities.[13] Moreover, even assuming for the sake of argument that these companies did have similar costs of capital, there are serious comparability problems stemming from differences in financial risks. These entities have a significantly higher equity thickness measured at both book and market values than do electric utilities or gas LDCs. While these companies have book value capital structures with 65-70% equity and market value capital structures with approximately 80% equity,

[11] This criterion seems to be the ratio of revenues resulting from the provision of retail energy services to total revenues for the sample company, although the workpapers are not clear on this point.

[12] Staff Report, p. 15. The full selection criteria are not listed there but have been retrieved from Staff Workpapers. However, the selection criteria are difficult to extract fully from the workpapers due to the quality of the copies and due to the vague nature of the footnotes.

[13] According to the companies' 2006 annual reports, Energen Corporation derives 85% of its net income from non-regulated oil and gas exploration and production while Questar derives 80% of its net income from oil and gas exploration and production, energy trading, and other non-regulated activities. National Fuel Gas derives the majority (about 61%) of its net income from regulated activities in the pipeline, storage, and utility industries with about 35% originating from oil and gas exploration and production.

the average electric utility has a much lower equity thickness measured at book value or at market value. Therefore, without an explicit adjustment for the difference in capital structures, they are not comparable to the Ohio EDUs. Table 1 below calculates the overall cost of capital that results from the Natural Gas Diversified companies while Table 2 converts the overall after-tax cost of capital into a cost of equity for the Ohio EDUs at their requested regulatory capital structure.

Table 1: Overall After-Tax Cost of Capital of Natural Gas Diversified Companies

Company*	DCF Cost of Equity [1]	Market Value Equity Ratio [2]	Cost of Debt [3]	Market Value Debt Ratio [4]	The Ohio EDU's Income Tax Rate [5]	Overall After-Tax Cost of Capital [6]
Energen Corp	7.9%	0.86	6.1%	0.14	37.1%	7.3%
Questar Corp	8.0%	0.89	5.9%	0.11	37.1%	7.5%
National Fuel Gas Co	9.3%	0.79	6.1%	0.21	37.1%	8.1%
Full Sample Average	8.4%	0.84	6.0%	0.16	37.1%	7.6%
Subsample Average	7.9%	0.87	6.0%	0.13	37.1%	7.4%

Q18. What are the implications of Table 1 and Table 2?

A18. Even if the Natural Gas Diversified companies had the same business risk as the Ohio EDUs (as is the implication to be drawn from the Staff Report's inclusion of them within

its "comparable" group of companies), the results shown in Table 2 and Table 3 would indicate that the Ohio EDUs should be allowed a return on equity in the range of 11¼% to 11¾%, which is well above the DCF estimates which range from 7.9% to 9.3% as reported in the Staff Report.[14] This illustrates why the Staff Report substantially underestimates the cost of equity when ignoring differences in financial risk.

Q19. You mentioned other concerns regarding the screening of these companies as well. Could you please elaborate?

A19. Yes. After companies of comparable business risk have been selected, the Staff screens out companies with characteristics that the Staff believes may bias the cost of equity estimates. However, it is a fundamental scientific principle that the screening process should not drive the results themselves. In particular, sample companies should not be screened out because they may have too high an estimated cost of equity. For example, screening out any company with a *Value Line* beta above 1.0 effectively means that the company was excluded because its estimated cost of equity would be too high and not because of fundamental analysis of any other characteristics of the company.

Q20. Why is it inappropriate to exclude companies with beta greater than 1.0?

A20. It is inappropriate to exclude companies with high betas if the companies have comparable risks to those of the Companies, and it is inappropriate to automatically delete high-beta companies when low-beta companies are not also deleted. In this case, American Electric Power, Dominion Resources Inc.[15] and Edison International had *Value Line* betas above 1.0 but met all of the other criteria specified in the Staff Report.

For example, these three companies are publicly traded entities on the New York Stock Exchange, reported by *Value Line* as electric utilities, have investment grade bond ratings, pay dividends, have market capitalizations greater than $1.5 billion, operate in the continental U.S., and have data available for analysis. Including these three companies in the sample would increase the Staff Report's CAPM estimated cost of equity by about 25

[14] See Schedule D-1.2, page 2 of 2.

[15] Dominion Resources failed the criterion that gas operating income to gas revenue be >= 5%, but in the context of a rate case for an electric distribution company, the relevance of this criterion is questionable.

basis points because the average beta increases from about 0.85 to about 0.89. A summary of the revised Staff Report's estimates is provided in Table 1 below.

Table 3

Staff CAPM Methodology	
Risk-free Rate	4.85%
MRP	6.50%
Average Value Line Beta	0.85
Return on Equity	10.39%

Sources and Notes:
Reports by the Staff of the Public Utilities Commission of Ohio.

Staff CAPM Methodology - Revised	
Risk-free Rate	4.85%
MRP	6.50%
Average Value Line Beta (Revised)	0.89
Return on Equity	10.62%

Sources and Notes:
Reports by the Staff of the Public Utilities Commission of Ohio.
Workpapers on Sample Selection of the Commission's Staff.

As noted above, the main problem with the exclusion of companies with betas above 1.0 is that the criterion drives the results whereas the purpose of sample selection criteria is to ensure that the sample companies and the target utility or utilities are of comparable business risk. The selection of sample companies should be based on the risk characteristics of the underlying assets – not on a measure, *e.g.,* beta, of the company's cost of capital.

Q21. Do you have any other concerns with the comparability of the Staff's proxy group?

A21. Yes. As noted above, the Staff Report does not consider differences in financial risk so even if the sample companies were of comparable business risk, their estimated cost of equity would not in general be appropriate for the regulated company. Also importantly, the Staff Report does not consider other risk factors that may affect the cost of equity. For example, many of the sample companies do not have a POLR obligation. This is a significant factor that must be considered when extrapolating results from the proxy group to the Ohio EDU's.

IV. IMPLEMENTATION OF THE DCF AND CAPM METHODOLOGIES

Q22. Please discuss Staff Report's implementation of the CAPM.

A22. This area of my testimony addresses Companies' Objection III.8. The Staff Report and the Vilbert Direct both relied on *Value Line* reported betas to apply to their selected comparable companies and both used a similar market risk premium of 6.5%.

However, the Staff Report did not consider a version of the CAPM that relies upon short-term interest rates. Short-term rates currently are very nearly the same as long-term interest rates, which is another way of saying that the yield curve is nearly flat. The short-term version of the CAPM provides additional information on the cost of capital for the sample companies. In this case, the short-term version is indicating that the cost of capital is higher than when it is estimated using the long-term version of the model. This provides one more reason that the allowed rate of return on equity should be set at the upper end of the range of estimates. In addition, as to determining the risk-free rate, Staff took the average of the yield on 10-year and 30-year Government bonds over a period of 52 weeks. Because the intent is to estimate the cost of equity going forward, the use of the average risk-free rate over 52-weeks seriously weakens one of the strengths of the model, i.e., that changes in interest rates are reflected in the cost of equity estimates. The data from as long as a year ago would be representative of today's environment only by coincidence. An average over a shorter period is much more likely to be representative of the cost of capital in the market. For example, I use an average bond yield over a period of 15 trading days (about 3 weeks) consistent with the time period the cost of equity models were estimated.[16] While the current difference between the 13-week average yield and the 52-week average yield is less than 10 basis points at this time, the procedure is nonetheless unreliable irrespective of the current outcome.

Nor did the Staff Report adjust for the fact that the CAPM is well known to underestimate (overestimate) the cost of equity for companies with betas less than (greater than) 1.0.[17] Additionally, by using an average beta for all of the companies in

[16] See Vilbert Direct, Table No. MJV-9.

[17] A matter compensated for with the use of the Empirical Capital Asset Pricing Model (ECAPM) as discussed in detail in the Vilbert Direct.

the sample, the Staff Report loses the ability to distinguish differences in financial risk among the sample companies. A company's estimated beta reflects both the business and financial risk of the company so valuable information is lost when using an average beta. In contrast, the use of the ATWACC approach captures both the business and financial risk of the sample companies so that the companies can be compared on a comparable basis.

Moreover, as discussed above, a significant problem inherent in the Staff Report's implementation of the CAPM is the exclusion of companies simply because they have a higher cost of capital than other sample companies. In this case, the omission of companies with a beta estimate above 1.0 is wrong.

Q23. Please describe the Staff Report's implementation of the DCF model.

A23. This portion of my testimony addresses Companies' Objection III.9. The DCF methodology used in the Staff Report is described as a so-called non-constant growth rate DCF or multi-stage DCF model. During the first five years, dividend and earnings are assumed to grow at a company's specific rate derived from forecasts of securities analysts. From year 25 onwards, the growth rate is assumed to equal an economy-wide GNP growth rate while the growth rates during years six to 24 linearly transition from the company specific rate to the economy-wide rate. Further, the Staff Report relies on company specific growth rates from several sources: Reuters, MSN, Yahoo, and various *Value Line* estimates. The relied-upon growth rate for each company is the average of the growth estimates from these four data sources. The economy-wide rate is calculated as the average of the U.S. GNP growth over the period 1929 to 2005.

Q24. Are there problems with the implementation of the DCF model in the Staff Report?

A24. Yes. There are several problems with the Staff Report's described implementation of the multi-stage DCF model. First, Staff Report's model is an annual version of the multi-stage DCF model, which fails to recognize that dividends are paid quarterly. The result is a downward bias in the cost of equity estimates because the dividend used in the annual model is calculated as the sum of the most recent four quarterly dividends instead of "annualizing" the most recent quarterly dividend by multiplying the most recent dividend by 4. The DCF model is derived using the assumption that dividends grow at a constant

rate. To the extent that dividends have increased over the most recent four quarters, the current dividend will be higher than the 4-quarter average. Moreover, the current stock price will reflect the fact that the current quarterly dividend is higher. Failing to recognize that the dividend has increased results in a mismatch between the stock price and the dividend in the model. As a test on the effect of this issue, I have replaced the sum of the dividend over the last four quarters with the annualized current dividend in the Staff Report's sample and replicated the Staff Report's DCF model. The average estimated return on equity for the sample increases by about 10 bps.

Second, the analysts' forecasts growth rates provided by Reuters, MSN, and Yahoo overlap. In other words, some individual analyst's forecasts may be counted more than once in the average upon which the Staff Report relies. The reliance on several sources does not necessarily provide additional information and is likely to lead to an unknown bias in the estimated growth rates. For example, if an individual analyst's forecast which is either very high or very low is included in each source, the impact of that estimate is multiplied by the number of sources used, whereas an analyst reported in only one source gets less weight. The solution is to rely upon one source of analyst forecasts as is done in the Vilbert Direct. [18]

Finally, the stock price used in the model is a 52-week average price. The use of such a long historical period obviates one of the primary advantages of the DCF model, i.e., that it is forward looking. Prices over a full calendar year cover the payment of at least four quarterly dividends and represents stale information. The estimated returns on equity will be too high if prices have generally been increasing or be too low if prices have generally decreased. In either case, the estimated cost of equity is not as accurate as it would be by relying on a shorter period to determine the initial price for use in the model.

[18] This problem does not arise in the Vilbert Direct's application of the model because only the average of the *Value Line* and Bloomberg analyst forecasts enters the calculation.

Q25. You have criticized the use of a 52-week average stock price in the DCF model. Does the use of an average price over a period of time avoid potential instability of the DCF estimates based upon spot stock prices?

A25. Yes, but the issue is not whether to use an average price over a period of time, but how long a period is reasonable. In my direct testimony, I use the average price over a period of 15 trading days (about a three week period) to avoid the potential problems with spot prices. In my judgment, that is preferable to a 52-week average which is unnecessarily long and is likely to lead to less accurate estimates of the cost of equity for the sample companies.

V. RISK, RETURN AND THE RELEVANT RETURN ON EQUITY

Q26. What topics do you cover in this section?

A26. First, I discuss additional risk factors facing the Ohio EDUs that the Staff Report did not consider. Second, I discuss recent legislative initiatives that will affect the Companies and investors' perceptions of risk - - hence the required cost of capital. Third, I discuss how the additional risk factors and recent developments in legislative initiatives must be taken into account in determining the cost of capital for the companies. Specifically, if the Ohio EDUs face asymmetric risk, then the Companies would not expect to earn their cost of capital on average.[19] This portion of my testimony addresses Companies' Objections III.6, III.10, and III.11.

Q27. Please elaborate on your first point regarding additional risk factors.

A27. Page 16 of the Staff Report reads:

> The Staff has explicitly not considered any additional risk factors relating to provision of electric generation service, inasmuch as FirstEnergy's proposed auction plan is designed to relieve the Company of such risk.

From this quote it is clear that the Staff Report did not consider additional risk factors. In doing so, the Staff Report failed to take into consideration whether the Companies' risk factors were comparable to those faced by the companies in the sample.

[19] See the Vilbert Direct pp. 9-10 for additional explanations.

It is important to note that the Ohio EDUs face some unique risk factors. For example, the Ohio EDUs have an obligation to serve as Providers of Last Resort ("POLR") in Ohio. If, for any reason, the Ohio EDUs do not expect to recover fully the costs of this obligation, then the Companies face an additional and asymmetric risk - - asymmetric because they would not expect to over-recover but may under recover the costs of providing the service. In addition, the outcome of the auction proposed by FirstEnergy is uncertain.[20] I am advised by counsel for the Companies that this is a proposal that has been filed with the Commission but has not been approved. Moreover, it is unknown when or whether the proposal may be approved by the Commission as filed or whether it will be modified in some way. I am further advised that no schedule for further proceedings on the proposal has yet been established. The proposal includes a three-year rate-increase phase-in if the auction results in prices that would increase residential rates by more than 15%.[21] The delay in recovery of costs imposes a cost on the Ohio EDUs and makes full recovery more uncertain.

Q28. Above you stated that legislative initiatives in Ohio likely will affect the Ohio EDUs and their investors. Please explain the relevant portions of the legislation.

A28. Currently, the Ohio legislature is considering legislation that may affect competition in Ohio. The current version of the bill (SSB 221, passed by the Senate) delays the adoption of a market-based process to procure power supply in Ohio. However, the bill has yet to emerge from the House of Representatives and may undergo revisions not only in that legislative chamber but in subsequent conference with the Senate. The bill likely would impact the Ohio EDUs substantially, as it may delay or (partially) abandon competition in Ohio.[22] According to FitchRatings, the current bill

> proposes two choices under the standard service offer (SSO): 1) a quasi cost-of-service electric security plan (ESP); and 2) a market rate option, under which the utility's SSO prices are periodically determined through an open, competitive bidding process, subject to numerous restrictions. Fitch believes

[20] FirstEnergy would procure supply for the Ohio EDUs.

[21] Energy Outlook, Ohio Market Update, July 31, 2007.

[22] The Ohio EDUs no longer own generation.

> that the restrictions imposed on the market rate option render this option unworkable as proposed ...[23]

In addition, the bill contains provisions regarding renewable standards, energy efficiency, ownership of generation, and other measures impacting utilities.[24]

Q29. How might this legislation affect the Ohio EDUs?

A29. First, because the legislation is currently under consideration and the final outcome is uncertain, the uncertainty adds risk to the Companies' operating environment. Second, the Ohio EDUs, pursuant to deregulation, divested their generation assets, so that a return to a "quasi" cost-of-service model may put them at a disadvantage compared to integrated electric utilities. Many of the companies included in the Staff Report's group of comparable companies are integrated electric utilities or located in jurisdictions that currently have no legislative efforts that might change or restructure their business environment with respect to competition and regulation. Therefore, this is a risk faced by the Ohio EDUs over and above that of the companies in the comparable sample. Third, if and when whatever proposed legislation is enacted into statute, there will still be a great deal of uncertainty surrounding the regulatory implementation of the statute's provisions. In general, investors dislike uncertainty and require a higher return as compensation for the risk inherent in such uncertainty. The Staff Report did not take these factors into account and therefore underestimated the Companies' cost of equity.

Q30. Based on the discussion above, what are your comments on Staff Report recommended range of 10.06% to 11.09% for return on equity?

A30. Based on the discussion above, the uncertainty about Ohio energy legislation, the possible changes in the competitive environment in Ohio, the Ohio EDUs' obligations to provide Standard Service Offer (or POLR), it is vital that the Ohio EDUs be capable of attracting capital on reasonable terms. The costs of underestimating the true cost of equity are often greater than overestimating it. An inadequate allowed rate of return on equity can deter capital investment particularly in a situation where access to capital

The assessment of risk, by investors and financial analysts -- and hence the determination of the required return and cost of capital -- is based upon the information, such as this report, which is published and available to the financial community.

[24] See, FitchRatings, *Op. Cit.*

markets may be more limited or more expensive than in the relatively recent past due to the effects of the sub-prime mortgage crisis. In situations where the regulated entity faces greater risks on average than the sample as well as possible asymmetric risk, it is important to look towards the upper end of the reasonable range. In this instance, the Staff Report estimates a range of 10.06% to 11.09%[25] compared to the estimated range of 11¼ to 12¼ percent in my direct testimony.[26] Because the Staff Report does not take the Ohio EDUs financial risk and other risk factors into account and because some of the sample companies and estimation procedures may bias Staff Report' cost of equity estimates downward, I continue to believe that a reasonable return on equity for the Ohio EDUs is in the range of 11¼ to 12¼ percent.

Q31. Does this conclude your Supplemental Testimony?

A31. Yes.

I. INTRODUCTION AND SUMMARY

Q1. Please state your name and address for the record.

A1. My name is Michael J. Vilbert. My business address is The Brattle Group, 44 Brattle Street, Cambridge, MA 02138, USA.

Q2. Did you previously file testimony in this proceeding?

A2. Yes, I filed Direct Testimony[1] ("Vilbert Direct") on behalf of Ohio Edison Company ("OE"), The Cleveland Electric Illuminating Company ("CEI") and The Toledo Electric Company ("TE"), (collectively, the "Companies" or the Ohio Electric Distribution Utilities ("Ohio EDUs")) in June 2007 regarding the return on equity that the Ohio EDUs should be allowed an opportunity to earn on the equity financed portion of their rate bases. I filed Supplemental Testimony ("Vilbert Supplemental") on behalf of the Companies in January 2008. Please see the detailed resume in Appendix A attached to my Direct Testimony for my professional qualifications.

Q3. What is the purpose of your rebuttal testimony?

A3. I have been asked by the Companies to comment on the testimonies of Mr. Aster R. Adams ("Adams Direct") on behalf of the Office of the Ohio Consumers' Counsel, of Mr. Richard C. Cahaan as Staff Witness ("Cahaan Direct"), and of Mr. Howard Sogalnick on behalf of the Ohio School Council ("Sogalnick Direct") with regard to the appropriate return on equity.

II. FINANCIAL RISK AND CAPITAL STRUCTURE

Q4. What are the issues in the Adams Direct regarding capital structure?

A4. The Adams Direct recommends using FirstEnergy's capital structure,[2] but that capital structure is not necessarily representative for the Ohio EDUs. Although financial risk is acknowledged as a component of a firm's risk[3], the Adams Direct does not consider the

[1] Company Exhibit 8.

[2] Adams Direct, pp. 5-6 and Attachment ARA-2.

[3] Adams Direct, p. 16.

impact on the required return on equity due to any difference in financial leverage between the sample and the regulated companies.

Q5. Please address the financial risk issue in the Adams Direct.

A5. The estimated costs of equity reflect *both* the business risk and the financial risk of the sample companies based upon the sample companies' *market value* capital structures.[4] If the market value capital structures of the sample firms were different, the estimated costs of equity would be different as well. As noted in the Vilbert Supplemental and the Vilbert Direct in Section II.C, "the ATWACC (After Tax Weighted Average Cost of Capital) – a company's overall cost of capital -- is constant over a broad range of capital structures. However, the cost of equity is not. The cost of equity for the Companies should reflect the risk of their underlying assets and be comparable to the return that is achievable on investments of comparable risk."[5] In other words, the Adams Direct does not adjust for the differences in the sample's capital structure nor for the fact that FirstEnergy's capital structure has greater financial risk than the regulatory capital structure filed by the Companies. Therefore a cost of equity recommendation that relied on the parent's capital structure would be higher than one that relies on the Companies' filed capital structure.

A. ATWACC AND MARKET-TO-BOOK ISSUES

Q6. Is it appropriate to estimate the cost of equity for the sample companies using market data?

A6. Yes. The Adams Direct, the Staff Reports and the Vilbert Direct all estimate the cost of equity for the sample companies using market information. The Discounted Cash Flow Model ("DCF" model) and the risk positioning model (i.e., the CAPM and ECAPM) rely upon market information, and the cost of equity estimates derived from those estimation models reflect the business risk and financial risk of the sample companies at their *market*

[4] Vilbert Supplemental, pp. 2-4.

[5] Vilbert Supplemental, pp. 4-7.

value capital structures.[6] The returns on equity recommended by the Adams Direct as well as by the Cahaan Direct and the Vilbert Direct are derived from these models.

B. THE ADAMS DIRECT'S CRITIQUE OF THE ATWACC METHOD

Q7. The Adams Direct claims that the ATWACC "method is flawed in that it tends to overstate the true cost of equity" and that "the underlying flawed assumption is that the Commission is obligated to maintain current stock price levels..."[7] Are these statements an accurate assessment of the ATWACC approach?

A7. No. The comments in the Adams Direct testimony demonstrate a misunderstanding of the ATWACC approach and its adjustment for financial risk. The Adams Direct claims that the ATWACC approach is an attempt to maintain a particular ratio of the market value of equity to the book value of equity (the "market-to-book value"), but this is incorrect. The market-to-book value is irrelevant to the ATWACC approach.

Q8. Please explain why the market-to-book ratio is irrelevant to the ATWACC approach?

A8. Note that in the formula (1) for the ATWACC displayed on p. 14 of the Vilbert Direct, book values do not appear in the calculation; therefore, there is no way that the ATWACC can anchor the market-to-book ratio. Regardless of the market-to-book ratio, what matters is the percentage of the market value capital structure that is equity relative to the percentage that is debt.

Q9. Please explain the apparent source of the misunderstanding of the ATWACC approach.

A9. One source of the misunderstanding is that the ATWACC is a *rate of return* not a dollar amount of return. The flaw in reasoning can be illustrated in the following simplified example. Suppose that the cost of equity estimated using the DCF or the risk positioning method is 10 percent for a regulated company with a market value capital structure with 67 percent equity and 33 percent debt. (See Step 1 in Figure 1 below.) Suppose that the

[6] This is well accepted financial theory. See, for example, Richard A. Brealey, Stewart C. Myers, and Franklin Allen, *Principles of Corporate Finance*, New York: McGraw-Hill/Irwin 8th ed. (2006) pp. 503-06.

[7] Adams Direct, pp. 18-19.

book value regulatory capital structure is 50 percent equity and 50 percent debt and that the ATWACC adjusted rate of return on equity is 12.1 percent. (See Step 2 in Figure 1 below.) Does this mean that if the Commission allows a 12.1 percent return on equity that the return on the market value of equity will be 12.1 percent? The answer, of course, is no.

Q10. Please illustrate why allowing an ATWACC adjusted return on rate base will not provide a rate of return on the market value of equity equal to 12.1 percent in the example.

A10. The reason is that the ATWACC adjusted return on equity is applied to the *book value* of equity in the rate base not the market value of equity. In this example, the market-to-book ratio is 2.0, so that the market value of equity is $1000 but the book value is only $500. A 12.1 percent rate of return on equity times a $500 book value of equity gives a return of about $60.70 which would be about 6 percent (i.e., 60.70/1000) on the $1000 of market value of equity. In other words, although the return on the book value rate base would be 12.1 percent in the example, the return on the market value of equity would be about 6 percent, ½ of the allowed return on the equity financed portion of the rate base. A 6 percent return on the market value of equity is likely to be less than the company's current market cost of debt. (See Step 3 in Figure 1 below.)

Figure 1: Example of ATWACC approach, and the resulting return on the market value of equity.

Step 1: Compute ATWACC using market values

	Market Values		Return	Tax Rate	Wt. Average
Equity	1000	67%	10.0%		0.067
Debt	500	33%	6.0%	40%	0.012
	1500	100%		ATWACC	**0.079**

Step 2: Using book value capital structure, compute allowed return on equity that yields the ATWACC determined in Step 1

	Book Values		Return	Tax Rate	Wt. Average
Equity	500	50%	12.1%		0.061
Debt	500	50%	6.0%	40%	0.018
	1000	100%		ATWACC	**0.079**

Step 3: Implied allowed equity return on market value of equity

	Dollar Amount	Rate of Return
Equity Return	60.7	**6.07%**

The example in Figure 1 illustrates an additional advantage of the ATWACC approach: rate payers are indifferent to the regulatory capital structure. The cost to customers would be unaffected by a different regulatory capital structure because the return on equity would change as capital structure changes in order to maintain a constant ATWACC, but the capital costs (i.e., the sum of interest expense, equity return and income taxes) paid by customers would not be affected by changes in capital structure.

Q11. If the allowed return on equity is 12.1 percent instead of 10 percent are you saying that this will or will not maintain the current market-to-book ratio?

A11. The ATWACC approach does not say anything about this. Instead, the ATWACC approach simply says that the estimated return on investments of comparable business risk to the regulated company is equal to the ATWACC. Therefore the regulated company should be allowed an overall *rate of return* equal to the ATWACC on the *book value* rate base.

Q12. Is the ATWACC method incompatible with the use of a book value rate base?

A12. No. The use of book value rate base is perfectly consistent with the use of a rate of return calculated from market data using the ATWACC method. The book value rate base is

merely a historical record of the costs of assets purchased by investors to provide service to customers. All rate-of-return analysts estimate a market cost of capital to apply to that investment, and as noted above, all three testimonies use market data to estimate the cost of equity for the sample companies. The only difference is that the Vilbert Direct calculates the overall market rate of return on all of the sources of capital for the sample firms and applies that overall rate of return to the rate base. Because the regulated capital structure differs from the market value capital structures of the sample companies, the allowed return on equity must be adjusted so that the weighted-average cost of capital used to set rates is equal to the market-determined overall cost of capital from the sample of companies with comparable business risk.

Q13. Do you have any comments on Table 3 in the Adams Direct?

A13. Yes. Table 3 is misleading. In Table 3, p. 21 the Adams Direct presents the average of Vilbert Direct's cost of equity estimates before any financial risk adjustment which he calls the "traditional methods". Mr. Adams then calculates what he characterizes as the "overstatement" of cost of equity as the average difference between the Vilbert Direct's cost of equity estimates before and after financial risk considerations. The differences average about 1.4 percent. The table goes on to calculate the adjusted ROE as my recommended cost of equity of 11¾ percent minus the 1.4 percent. This fails to take into consideration that the average of the Vilbert Direct's DCF and risk positioning estimates is 10.7 percent not the 10.3 percent that results from subtracting 1.4 percent from 11.75 percent. The Adams Direct simply misrepresents the Vilbert Direct's results. If the Adams Direct wants to refer to an average of the "traditional" cost of equity estimates in the Vilbert Direct, the proper figure is 10.7 percent shown in Table 3, not the 10.3 percent cited, but in any event this value ignores the financial risk and would not be correct for the Companies.

C. THE CAHAAN DIRECT'S CRITIQUE OF THE ATWACC METHOD

Q14. How does the Cahaan Direct address financial risk?

A14. The Cahaan Direct also accepts the importance of financial risk and evaluates the ATWACC approach. The Cahaan Direct concludes that because the market value capital structure of FirstEnergy is not substantially different from the average market capital

structure of the sample companies, there is no need for an adjustment for differences in financial risk.[8]

Q15. Is the Cahaan Direct correct that the financial risk of FirstEnergy, the parent company, is comparable to the sample compared on a market value basis?

A15. Yes, but that is not the right question. This proceeding is directed toward setting the appropriate return on equity on the rate base for the Ohio EDUs not FirstEnergy. The appropriate comparison is between the regulatory capital structure of the Ohio EDUs and the (market value) capital structure of the sample companies because the costs of equity estimated by the models (i.e., the DCF and the CAPM) reflect the business and financial risk of the sample companies at their market value capital structures.

Q16. Please continue.

A16. The Cahaan Direct's concern seems to stem from the relatively high market-to-book value ratios of the sample companies, but that issue is a distraction from the point being made by the ATWACC approach. The market-to-book ratios are irrelevant to the ATWACC approach. This was discussed above but another way to think about this is to consider a world in which the market-to-book ratios are always equal to one for all of the sample companies. If the sample companies' average capital structure was one with 67 percent equity and the regulated company's capital structure was one with 50 percent equity, there would seem to be little disagreement that the financial risk of the sample was lower than for the regulated company, but it would have absolutely nothing to do with the market-to-book ratio. In particular, the ATWACC method is not a method to introduce the market-to-book ratio through the "backdoor" as is of concern in the Cahaan Direct.[9]

Q17. Do the cost of equity estimates from the DCF model and the CAPM depend upon the market value or book value capital structures of the sample companies?

A17. The market value capital structure is the relevant measure of financial risk. The market determined cost-of-equity estimates from the sample depend upon both the business and the financial risk of the sample. The financial risk of the sample companies depends

[8] Cahaan Direct, pp. 26-28.

[9] Cahaan Direct, p. 28.

upon the market value not the book value capital structures. There is no debate in financial theory that financial risk is a function of market value capital structures.

Q18. Please continue with the example.

A18. In the example, the average capital structure of the sample companies is 67 percent equity even though the market-to-book ratios are all equal to one, but the regulated company's capital structure has only 50 percent equity. Applying the cost of equity from the sample in this situation without consideration of the differences in financial risk would clearly be wrong. Anyone disagreeing with the last statement should consider whether their answer would change if the regulatory capital structure had 80 percent equity or 90 percent equity instead of 50 percent.

Q19. But the sample companies and FirstEnergy's market-to-book ratios are not equal to one. Doesn't that change the example?

A19. No. First, again note that the market-to-book ratio does not enter the calculation of the ATWACC for the sample companies. It is all based upon the market value capital structures and the market costs of debt, preferred stock and equity. Second, the cost of equity estimated from the market models still reflects the business and financial risk of the sample companies at their market value capital structures not their book value capital structures. Third, applying the cost of equity estimated from the market models to the regulated entity still requires consideration of the differences in capital structures between the sample and the regulated company just as when the market-to-book ratios were all equal to one. Nothing of consequence has changed for application of the ATWACC to the regulated entity due to the market-to-book ratios. Finally, note that there is nothing inconsistent with applying the ATWACC to a book value capital structure. Nothing I am recommending would change the way the Ohio EDUs are regulated or would change the reliance on a rate base established on a book value basis. What the ATWACC approach does do is change the way that the information from the market models is interpreted for application to the book value rate base. Specifically, the ATWACC approach recognizes that as the capital structure changes, the return on equity must change as well in order to be consistent with the market determined cost of equity estimates from the sample.

III. ESTIMATING THE SAMPLE COMPANIES' COSTS OF EQUITY

Q20. Do you have any comments on the cost of equity methodologies relied upon by the Adams Direct and the Cahaan Direct?

A20. Yes. My comments in this section are primarily addressed to the Adams Direct because the methodologies used by the Staff were addressed in my Supplemental Testimony. I do note several places, however, that the Cahaan Direct agrees with my approach and rejects several aspects of the way the Adams Direct implements the models. With regard to the Adams Direct, I first address the implementation of the DCF method. Next, I address the implementation of the CAPM, and finally, I discuss the Adams Direct's critique of the Empirical Capital Asset Pricing Model ("ECAPM").

A. THE DCF MODEL

Q21. What comments do you have regarding the Adams Direct's implementation of the DCF model?

A21. The Adams Direct implements the DCF model in a manner very similar to the Staff's implementation, so the comments in my Supplemental Testimony apply equally to the Adams Direct's implementation.[10] Specifically, there are two problems with the DCF model in the Adams Direct. The first is that the Adams Direct relies on stock prices that are up to a year old. Because the DCF model is intended to be a forward-looking model, it is important that the stock prices in the model reflect current information. The calculation of the dividend yield in the Adams Direct with reference to a yearly average price destroys one of the primary advantages of the DCF model in that it is a forward looking model. Stock prices averaged over an entire year reflect stale and out of date information. One need only consider the developments in the credit markets due to the subprime mortgage crisis to realize how out of date information from a year ago truly is. A year is simply too long a time period to rely on for the purpose of calculating the current price and yield.

[10] Vilbert Supplemental, pp. 13-14.

Q22. What is the second problem in the Adams Direct implementation of the DCF model?

A22. The Adams Direct summarizes the dividend payments over the last four quarters rather than annualizing the most recent dividend, i.e., multiplying the most recent dividend by four. This procedure will definitely *underestimate* the cost of equity using the DCF model. As noted above the DCF model assumes that dividends growth each period by the assumed constant growth rate. Using historical dividends from as much as a year ago violates the constant growth assumption and in general will underestimate future dividends to the extent that dividends paid have increased over the last four quarters. As with using historical prices from a year ago, this procedure weakens the forward looking nature of the model.

Q23. Do you have any other comments on the Adams Direct's reliance on the DCF model

A23. The Adams Direct seems to believe that the DCF model provides more reliable estimates of the cost of capital for the sample companies than the risk positioning model does at this time, but that belief is highly debatable at best.[11] As noted in the Vilbert Direct,[12] the DCF model can be a useful model if its assumptions are fully met, but those assumptions are so unlikely to be satisfied and also have such a large effect on the estimated cost of equity it produces that it is unusual for the conditions necessary for the completely reliable implementation of the model to be present. In other words, changing the "assumed" terminal growth rate as well as when the terminal growth rate will be achieved in the non-constant growth formulation of the model changes the DCF estimates substantially, but there is literally no information upon which to base those assumptions.

[11] The Surface Transportation Board recently decided to switch from using the constant growth DCF to the CAPM to determine the cost of capital for railroads citing among other factors, the assumption of a constant growth rate and a constant dividend payout ratio not being generally true. See *Surface Transportation Board* Decision STB Ex Parte No. 664, "Methodology To Be Employed In Determining The Railroad Industry's Cost Of Capital," January 17, 2008.

[12] Vilbert Direct, p. 23.

B. THE CAPM

Q24. Do you have a general comment on the Adams Direct's implementation of the CAPM?

A24. Yes. In general, most of the procedures used in the Adams Direct have the effect of an unwarranted reduction in the estimated return on equity, a point with which the Cahaan Direct agrees when it says that "[c]onsidering the current yields on FirstEnergy operating companies' long-term bonds, and bonds of similar quality, the risk premium implied by the [Adams Direct's] 8.61% or the 8.33% estimates are simply too low to be credible."[13]

Q25. Do you have any comment on the method that the Adams Direct uses to estimate the parameters for use in the CAPM?

A25. Yes. The Adams Direct estimates all of the parameters in the model by taking averages of different information sources irrespective of whether it is appropriate to do so. For example, Mr. Adams calculated the sample companies' betas as the average of the betas estimated by *Value Line*, Bloomberg's, and Reuters,[14] two of which adjust betas and one of which does not. Rather than make a judgment whether betas should be adjusted or not, the Adams Direct simply averages different estimates. A similar approach is used for the risk-free rate where the Adams Direct relied on the average of yield on 10-year and 30-year Treasury bonds for a full year ending in November 2007. This is a problem because the MRP should be matched with the measure of the risk-free being used. The average yields on 10-year Treasury bonds are generally lower than the yields on 30-year Treasury bonds, so the MRP used with the yields on 10-year Treasury bonds compared to 30-year Treasury bonds should be different as well. Moreover, interest rates that are as much as a year old are stale and out of date which destroys the forward looking aspect of the CAPM. Similarly, the Adams Direct averages many estimates of the MRP including geometric and arithmetic from many sources to determine the MRP for use in the models. While

[13] Cahaan Direct, p. 25.

[14] *Value Line* betas are estimated using five years of weekly returns and the New York Stock Exchange Composite Index as the market proxy. *Value Line* betas are adjusted. Reuter's betas are estimated using five years of monthly returns and the S&P 500 as the market proxy. Reuter betas are not adjusted. Bloomberg allows its user to determine the frequency as well as the time horizon over which betas are estimated. However, the standard is two years of weekly data. Bloomberg generally uses the S&P 500 index and allows its user to determine whether the betas are adjusted. In this case, the Bloomberg betas are quite similar to those obtained from *Value Line*.

such an approach reduces the effect of the analyst's judgment, it also has the effect of making the analyst more of a calculating machine than an expert making judgments about the weight of the evidence. The point is that simply averaging many values for a parameter does not improve the estimate if the values being averaged are not appropriate.

Q26. The Adam Direct relies on estimates of the MRP based upon the geometric mean. Is this appropriate for use in the CAPM?

A26. No. Although the Adams Direct cites a few sources in favor of relying on the geometric average in some circumstances to determine the market risk premium, this is not currently standard practice in finance and is specifically recommended against by nearly every academic source. The Cahaan Direct agrees that the arithmetic average is correct for use in the CAPM.[15] The inappropriate use of the geometric estimate of the MRP accounts, in part, for the exceptionally low CAPM cost of equity estimates in the Adams Direct.

Q27. Do you have other comments on the Adams Direct's estimation of the MRP for use in the CAPM?

A27. Yes. The Adams Direct's discussion of the literature on the market risk premium does not include any articles more recent than 2005. Many of the more recent articles support a higher estimate of the MRP. In addition, the Adams Direct goes through substantial effort to calculate the ex ante risk premium based upon an original article by Ibbotson and Chen and subsequently relied upon by Professor Randall Woolridge in a different proceeding, but these calculations are unnecessary because Morningstar publishes the Ibbotson and Chen ex ante risk premium in their *Valuation Edition* yearbook.

Q28. Please elaborate on the market risk premium issue.

A28. As discussed in the Vilbert Direct, there is currently no consensus on the market risk premium. However, the Adams Direct does not cite a full spectrum of the literature that focuses on this issue. For example, the Adams Direct cites a 2003 publication of Dimson, March and Staunton in support of a relatively low market risk premium.[16] However, in

[15] Cahaan Direct, p. 12 cites p. 77 in the Ibbotson SBBI Valuation Edition Yearbook 2007 which states that the arithmetic mean is the appropriate measure of the MRP for use in the CAPM.

[16] Adams Direct, p. 40.

their most recent publication, Dimson March and Stauton (2007) estimate the arithmetic mean historical market risk premium at 6.6 percent relative to Treasury bonds for the U.S.[17] It is also noteworthy that another regulator, the Surface Transportation Board, in its recent decision to rely on the CAPM decided after extensive review that the Morningstar/Ibbotson historical arithmetic average from 1926 to today was the most appropriate estimate of the MRP.

> We are now persuaded that basing the equity-risk premium on returns dating from 1926 is the superior and more standard approach. We are cognizant of the literature, cited by several parties, indicating that some experts believe that the forward-looking equity-risk premium should be lowered to reflect the impact of higher price/earnings ratios. For example, the expert for the AAR directed the agency to an adjusted equity-risk premium published by Morningstar/Ibbotson that seeks to reflect the upward trend in price-earnings ratios and reduces the forward-looking equity-risk premium. We acquired the cost-of-capital book published by Morningstar/Ibbotson so that we might carefully review that alternative figure. But while Morningstar/Ibbotson does report such a figure, which falls in the 6% range, the company itself continues to rely on returns dating from 1926 in its own CAPM calculations. Moreover, WCTL submitted evidence showing that most commercial vendors of cost-of-capital information use this same figure in their CAPM calculation. Accordingly, we will follow the standard approach and use the historical average from 1926. [footnotes omitted][18]

Q29. Earlier you noted that the Morningstar publishes its forecast of the Ibbotson and Chen ex ante risk premium in its Valuation Edition Yearbook so that there was no need to calculate the value. What is the forecast in the 2007 Yearbook?

A29. The arithmetic forecast is 6.35 percent over Treasury bonds, which is very similar to the 6.5 percent MRP used by both the Vilbert Direct and the Staff Reports. The geometric mean ex ante MRP is 4.33 percent.[19] Note that the Adams Direct calculates the ex ante geometric risk premium to be 4.64 percent, which is equal to 6.66 percent on an arithmetic basis. As noted in the Morningstar *Valuation Edition*, for "use as the expected equity risk premium in either the CAPM or the building block approach, the arithmetic

---

[19] Morningstar, SBBI Valuation Edition, 2007 Yearbook, p. 96.

calculation is the relevant number."[20] In other words, the Adams Direct ex ante MRP should be about 200 basis points higher than the 4.64 percent geometric average used in the calculations.

Q30. The Adams Direct also argues that survivorship bias leads to an overstatement of the historical market risk premium by as much a 1.50 percent.[21] Does this represent the most recent view in the academic literature?

A30. No. There are newer academic articles that find the survivorship bias to be very minor. As noted in the Vilbert Direct, Jorion and Goetzmann (1999) found the survivorship bias to be only 29 basis points.[22] The 2006 version of the Dimson, Marsh and Staunton article cited by the Adams Direct calculates that the survivorship bias is de minimus, about $1/10^{th}$ of 1 percent, i.e., 0.1 percent not 1.50 percent referenced in the Adams Direct.[23] Dimson et al note that higher estimates of the survivorship bias requires implausibly low probabilities of the long-term market survival, but such low probabilities contradict the history of world equity markets.

Q31. The Adams Direct relies on the geometric market risk premium which is inconsistent with standard financial economics. Please explain why the geometric market risk premium is inappropriate for cost of capital estimation.

A31. While the Adams Direct cites a few sources in support of the geometric market risk premium, it is not standard practice in finance. In general, those articles rely on serial correlation in market returns as justification of use of the geometric average, but those articles also suggest weighting the arithmetic and geometric means with by far the greatest weight on the arithmetic mean. Although the geometric mean return is appropriate for consideration of achieved returns over a period of time, it is well established that the geometric mean is not correct for estimating the expected return. Based on current academic and other literature, the geometric average based MRP is not

---

[21] Adams Direct p. 39.

[22] Jorion, P., and W. Goetzmann (1999), "Global Stock Markets in the Twentieth Century," *Journal of Finance* 54:953-980. See also the Vilbert Direct, pp. B-6 to B-7.

[23] *The Worldwide Equity Premium: A Smaller Puzzle*, Revised 7 April 2006, by Elroy Dimson, Paul Marsh, and Mike Staunton, London Business School, p. 22.

appropriate for estimating cost of capital in a regulatory setting because the CAPM requires a forward looking perspective. This is well understood in the broader finance community. A few examples of current publications stating that the arithmetic mean not the geometric mean is correct are Ibbotson Associates, *Stock, Bonds, Bills and Inflation, Valuation Edition*, 2007 Yearbook, p. 77, Roger A. Morin (2006), *New Regulatory Finance*, Public Utilities Reports, Inc., pp. 116-117, the *Investments* text by Professors Bodie, Kane, and Marcus (2005) Zvi Bodie, Alex Kane, and Alan J. Marcus (2005), *Investments*, 6th Edition, McGraw-Hill, p. 865, and *Principles of Corporate Finance*, 8th Edition, McGraw-Hill, by Richard A. Brealey, Stewart C. Myers, and Franklin Allen (2006), pp. 150-151.

Q32. The Adams Direct also claims that the *Value Line* betas are over estimated because they are calculated with regard to the NYSE Index as opposed to the S&P 500 Index for the market proxy.[24] Is this a valid concern?

A32. No, not in my opinion. In fact, I have never heard anyone claim that the choice of either the S&P 500 Index or the NYSE Index has a significant effect on the estimation of beta. Moreover, I am highly skeptical of this assertion because the correlation between the NYSE Index and the S&P 500 Index is very high, on the order of 0.98 depending upon time period,[25] so that betas estimated against one index are likely to be very similar to betas against the other index. Recall that beta is a measure of the correlation of a company's stock returns with the returns on the market.

[24] Adams Direct, p. 35.

[25] The correlation is 0.98 for the period January 1988 to September 2007.

C. THE ECAPM

Q33. The Adams Direct claims that "an ECAPM analysis using adjusted betas rather than raw betas double-counts the empirical effect of historical Betas"[26] and that "The use of Value Line betas in Dr. Vilbert's ECAPM analysis results in an overstatement of the cost of equity."[27] Do you understand the nature of the Adams Direct's concern?

A33. Yes. The Adams Direct does not dispute the fact that the security market line is flatter than predicted by the CAPM nor does it dispute that this can be captured by the ECAPM as modeled in the Vilbert Direct. Indeed, the Adams Direct states the belief that: "If one is going to use the results of the ECAPM to adjust a CAPM result, one must begin in the same place that the ECAPM begins – with raw Betas."[28] This explicitly acknowledges the Adams Direct's acceptance of the validity of the ECAPM relationship. The Adams Direct does dispute, however, the use of *Value Line* betas in conjunction with the ECAPM framework. Specifically, Mr. Adams believes that *Value Line's* adjustment of the estimated betas towards one already captures the ECAPM relationship.

Q34. Is this true?

A34. No. The interpretation of the literature on the ECAPM contained in the Adams Direct is not accurate. Mr. Adams makes the unsubstantiated claim that "the use of a Value Line Beta in a CAPM equation more than adequately compensates for the empirical evidence relied upon by Dr. Vilbert."[29] The argument relies upon the faulty premise that the ECAPM empirical results are formed with "raw betas" and *Value Line* betas are something else. The important point to remember is that the *Value Line* adjustment is made to an *estimated* beta, not the actual underlying beta.[30] If the actual beta were known, adjustment would not be necessary – indeed, there would be no need for

[26] Adams Direct, p. 22.

[27] *Ibid.*, p. 22.

[28] *Ibid.*, p. 22.

[29] Adams Direct, p. 23, ll. 9-11.

[30] It should be noted that this adjustment is a common one in the industry (e.g., Merill-Lynch, Bloomberg).

estimation at all.[31,32] The purpose of *Value Line* beta adjustment is to compensate for beta estimation error in order to produce as accurate an estimate of the actual (unobservable) beta as possible. Contrary to the claims in the Adams Direct, the empirical research underlying the ECAPM does not describe a relationship between estimated betas (i.e., "raw betas") and expected returns.[33] Instead, these studies typically use an alternative method to correct for sampling errors in order to form unbiased estimates of actual betas.[34] Specifically, they typically employ a sophisticated methodology relying on specially designed portfolios to remove the sampling error. These studies therefore tell us that after adjusting for sampling error as much as possible, there is still a flattening of the security market line relative to the CAPM relationship. So whether one uses an adjustment as done in these studies, or one uses a (2/3, 1/3) weighting as done by *Value Line* to transform raw beta estimates into unbiased estimates of true betas, an adjustment is still unaccounted for in the security market line. This point is particularly clear from the results in the article by Litzenberger, Ramaswamy, and Sosin (1980), which explicitly uses both "raw" and "adjusted" betas to map the empirical market line. With "raw" betas, the results support the use of a 3.912 percent alpha factor, whereas with adjusted betas, this alpha factor is about 1.932 percent.[35] In other words, even if the actual beta of a stock were known, an "alpha" term of almost 2 percent would still be necessary to capture the empirical relationship between individual security excess

[31] If the actual beta were unchanging, then an over-estimate of beta in one time period will make it more likely that an underestimate will be observed in the next – which results in the regression towards mean phenomenon. There is also evidence that betas of continuing firms tend to trend towards one. Together, these suggest that historical betas are biased estimators of true betas – using the *Value Line* type adjustment has been shown to be a very good estimator of true betas in this circumstance.

[32] Professor Blume first documented the need for the *Value Line* style adjustment. See Blume, Marshall E. (1971), "On the Assessment of Risk," *The Journal of Finance*, 26(1), pp. 785-795. The empirical fact has been replicated and widely acknowledged ever since.

[33] A representative list of articles that support the ECAPM approach is included in Appendix C, Table No. MJV-C1 included in the Vilbert Direct. See also "The Capital Asset Pricing Model: Theory and Evidence," Eugene F. Fama and Kenneth R. French, *The Journal of Economic Perspectives*, Vol. 18, No. 3 (Summer, 2004), pp. 25-46.

[34] Litzenberger, Robert H. and Krishna Ramaswamy and Howard Sosin. (1980), "On the CAPM Approach to Estimation of a Public Utility's Cost of Equity Capital," *The Journal of Finance* 35 (2), pp. 369-387.

[35] Although one might suggest that one should use the same portfolio methodology as in the papers instead of the *Value Line* adjustment, this is cannot be used to provide an unbiased estimate of an individual company's beta without excessive complication (i.e., it is designed for portfolios).

returns and market excess returns. This is precisely what I have done in the Vilbert Direct.

IV. DETERMINING THE OHIO EDUs' COSTS OF EQUITY

Q35. Mr. Adams claims that his recommended return on equity and resulting overall weighted-average cost of capital is reasonable because it is consistent with historical returns on total capital earned by a group of electric utilities covered by *Value Line*. Are the returns reported by *Value Line* a relevant comparison for this rate case?

A35. No. There are several problems with the return comparisons in Tables 6 and 7 of the Adams Direct. First, the realized returns listed are those of FirstEnergy and not those of the Companies. Second, the historical returns are not necessarily compatible with those required going forward, and third, the method of calculating these returns makes them meaningless for comparison to the required returns for the regulated companies.

Q36. Do you have any comments on the level of the recommended return on equity?

A36. Yes. The Adams Direct recommends a cost of equity below what is the norm for investment grade rated public utilities which in and of itself indicates that the recommendation is too low. The 9.26 percent return on equity that Adams Direct recommends is well below the median return on equity for utilities that have a BBB credit rating as determined by Standard & Poor's.[36] This is an indication that the recommendation is likely to be viewed as very low by the investment community which is troublesome given the planned capital expenditure by the Ohio EDUs of almost $1.8 billion through 2011.[37] In this regard it is noteworthy that while Moody's Investors Services, Inc. ("Moody's) rates Ohio Edison Company Baa2, both The Toledo Edison Company and The Cleveland Electric Illuminating Company have Baa3 credit ratings by Moody's. The Baa3 rating corresponds to the lowest investment grade rating from Moody's.[38] In the current environment of substantial need for infrastructure expenditure

[36] Standard & Poor's, Corporate Ratings Criteria 2007, p. 43.

[38] Direct Testimony of James F. Pearson on behalf of the Ohio EDUs ("Pearson Direct"), pp. 6-7.

and "[m]ore-expensive and less-available credit",[39] setting the allowed rate of return below what investors expect is likely to hurt not only the Companies but in the long run consumers as well, because the funds for needed investments may be more costly, more difficult to obtain, or both in today's credit markets. Given that two of the three Ohio EDUs are at the bottom at the investment grade credit ratings scale, it is essential that the Ohio EDUs' credit ratings remain investment grade in order to maintain full access to capital markets.

Q37. Please elaborate on need to access capital markets.

A37. The September 28, 2007 *Value Line* report points to the need for substantial investment in generation and transmission,[40] a point also mentioned in several reports commissioned by the *Edison Electric Institute,*[41,42] but the industry is in a period of great uncertainty. For example, the prices of fossil fuels have increased dramatically and have become much more volatile over the last few years. Construction prices for all facilities have recently increased rapidly, and uncertainties exist about how the rise in prices will affect the infrastructure investment strategy:

> However, rising construction costs will put additional upward pressure on retail rates over time, and may alter the pace and composition of investments going forward. The overall impact on the industry and on customers, however, will be borne out in various ways, depending on how utilities, markets and regulators respond to these cost increases.[43]

Second, public concern with environmental sustainability and the need for renewable sources of energy has led to the adoption in many states of renewable generation requirements.[44] It seems certain that environmental concerns will increase in the future and may lead to new restrictions on emissions from power plants, but the impact of these

[44] "The Impact of a Federal Renewable Portfolio Standard," North American Power Service Insight, Wood Mackenzie, February 2007.

concerns on renewable energy requirements and restrictions on green house gases is uncertain. These uncertainties are a clear source of risks for electric utility investors. For example, at the Federal level, the House passed a bill this summer proposing a 15 percent renewable energy requirement by 2020, while an earlier Senate bill on energy did not include a similar requirement.[45] Clearly, environmental issues are an important source of uncertainty about future costs and regulation, and increase the risk of regulated electric utilities.

Q38. Please summarize your conclusions regarding the stability of the electric utility industry at this time.

A38. The future development of the electric industry is uncertain at this time, and the natural gas industry must deal with rapidly increasing commodity prices and decreasing average consumption so the stable conditions necessary for the reliable implementation of the DCF model are not present at this time for either industry. The future structure of the electric utility industry is far from certain, and the uncertainty regarding the future direction of the electric industry makes access to capital markets more difficult. The industry faces the need for substantial capital investment going forward to meet the challenges of new environmental and safety standards as well as the need for conservation. Acquiring the capital necessary for the required investments will require a supportive regulatory environment including an adequate return on equity.

Q39. Aren't most of the factors leading to instability in the electric industry factors that affect generation or transmission only and as such would not be relevant to the risk of the Ohio EDUs?

A39. No. While many of the risks specifically affect generation, the risks are not restricted to that portion of the industry, and investors are well aware of the turmoil and uncertainty in the electric industry. Although generation is not part of the Ohio EDUs rate base, the Companies have a Provider of Last Resort ("POLR") obligation which is accompanied by a great deal of uncertainty at this time. To the extent that the mechanisms for the recovery of the costs of procuring power for customers have not been resolved, the

[45] These pieces of legislation have been widely reported in the national press. For a specific reference, see *Edison Electric Institute* press release of August 4, 2007, available at http://www.eei.org/newsroom/press_releases/070804.htm.

uncertainty throughout the electric industry and particularly in the cost of power will increase the risk and uncertainty of the Ohio EDUs.

Q40. Are there other issues with how the Adams Direct arrived at its cost of equity recommendation?

A40. Yes. Mr. Adams does not address Ohio specific risk factors in his testimony. As I explained in my Supplemental Testimony, the fact that the Ohio legislature is considering legislation that may affect competition in Ohio adds uncertainty to the Ohio EDUs operating environment. In the Vilbert Supplemental, I discussed the potential impact of the legislation and concluded that not considering these factors will likely lead to an underestimation of the cost of equity. Details are provided in the Vilbert Supplemental at pp. 15-17.

Q41. Are these risk concerns similar to the POLR concerns you noted in the Vilbert Direct.

A41. Yes. POLR obligations may also impose an asymmetric risk on the company which must be recognized and evaluated when drawing cost of capital conclusions from the benchmark samples.

Q42. Mr. Adams also testified about the risk arising from the Ohio EDUs' POLR obligations and whether the pending legislation in Ohio increased the Ohio EDUs' risks.[46] What is your response?

A42. The Ohio EDUs' POLR obligations increase the risk of the Ohio EDUs relative to the sample companies in the Vilbert Direct because the precise mechanisms by which the recovery of the costs of acquiring power for the Companies' customers has not been resolved. The outcome of the pending legislation in Ohio may or may not increase the risk of the Ohio EDUs' POLR obligations, but my point is that the outcome of the legislation as well as the mechanism for acquiring power for customers and recovering the costs of the power have not been finalized. As a result, there is a great deal of uncertainty facing the Ohio EDUs with regard to their POLR obligations. As a general observation, investors dislike uncertainty and demand higher returns in compensation.

[46] Hearing Transcript, February 12, 2008, pp. 70-74.

Q43. Do you have any evidence that POLR risk has been a problem in other jurisdictions?

A43. Yes. The experience of distribution utilities in some other states has not been favorable. Note that the point in the following examples is not whether the regulatory environment in Ohio is similar to that in other states, but rather that investors are well aware of the kinds of things that can go wrong. Investors must make judgments as to the ultimate resolution of the issues in Ohio and will recognize and price the uncertainty of the outcome. For example, in Illinois the legislation arbitrarily renewed a price cap in spite of the fact that the cost of power had increased substantially. As a result, the rating agencies immediately downgraded some of the state's utilities' credit ratings.[47] In Maryland, similar uncertainty occurred regarding the full recovery of the costs of acquiring power as the prices of power increased dramatically.[48] As with a policy of reducing the cost of equity only in an era of declining performance, POLR obligations typically impose significant asymmetric risks on a company's equity returns. All else equal, investors respond to this by lowering the value they place on equity which has a direct impact on the company's cost of capital. To ignore this fact and treat the Companies as if they are of the same business risk (and have the same cost of capital) as the benchmark samples risks a material error in the cost of capital for the Companies.

Q44. But is the risk of the Companies' POLR obligations a topic that should be considered here given the notion that the Commission and/or the legislature will take care of things and not leave the Companies in a bind?

A44. In my opinion, this proceeding should consider the uncertainty and corresponding risk of the Companies' POLR obligations because it is a risk that is relevant to the Companies at this time and will continue to be a risk until the uncertainty is resolved. Although some parties here may have confidence that the POLR issue will be adequately dealt with by the Commission, this confidence does not set the cost of capital – investor expectations and uncertainty does. Since there has been no settlement of this issue as yet, investors

[47] See for example, Moody's Investors Service, Rating Action, "Union Electric Company," 12 March 2007 and "Fitch Downgrades ComEd's Ratings; Remains on Rating Watch Negative," Fitch Ratings, 9 March 2007.

[48] See for example, Fitch Ratings, "U.S. Power and Gas 2007 Outlook for Key Credits," Corporate Finance, December 16, 2006 and "BGE: Cap on Rates May Force Bankruptcy," *Baltimore Business Journal*, February 17, 2006.

still face material uncertainty as to how this issue will ultimately be resolved, when it will be resolved, and even if it will be resolved. This continuing uncertainty means continuing additional risk for investors, which means a higher cost of capital relative to a sample of companies without POLR obligations.

Q45. Do you have any evidence that investors feel this way?

A45. Yes. For example, Moody's Industry Outlook for the U.S. Electric Utility Sector specifically mentions the risk associated with the transformation of the industry in the states that started on the path of restructuring in the late 1990s.[49] Similarly, S&P in its "Top 10 U.S. Electric Utility Credit Issues For 2008 And Beyond," discusses the issue of regulatory and legislative backlash against rising energy prices as a risk for investors and notes "[l]ooming battles over transition rules in Ohio and Pennsylvania may not be as contentious [as those in Maryland and Illinois], but there is risk that electric providers could be harmed."[50] Fitch Ratings also notes that "[e]lectric utilities that emerge from rate freezes or multi-year tariff settlements or subject to disproportionate increases in costs and in greatest need of tariff increases remain most at risk. The risk is heightened by the convergence of rising costs for fuel, equipment and maintenance materials, pension and medical benefits, and infrastructure investments."[51]

Q46. But if you consider POLR obligations as a basis for moving towards the higher end of a cost of equity range, should you not also consider mechanisms that reduce the risks faced by the Companies?

A46. If such mechanisms existed and actually reduced the systematic risk of the Companies, then certainly they should be considered as well.

Q47. The Solganick Direct identifies the new rate design proposal by the Companies as one such mechanism. In fact, Mr. Solganick recommends reducing the recommended cost of equity by 50 basis points for the cost of service allocation to a specific set of customers because of the rate design supposed reduction in the

[49] "Industry Outlook – U.S. Electric Utility Sector," January 2008, Moody's Corporate Finance, pp. 7-9.

[50] "Top 10 U.S. Electric Utility Credit Issues For 2008 And Beyond," Standard & Poor's Ratings Direct, January 28, 2008, p.3.

[51] U.S. Utilities, Power and Gas 2008 Outlook," Fitch Ratings, Corporates, December 11, 2007, p.5.

Companies' business risks.[52] Do you believe that this reduction in the cost of equity is appropriate?

A47. No. First, I disagree with the claim that this mechanism reduces the risk that is *relevant* to the required rate of return on equity. The Solganick Direct draws a parallel between the new rate design policy and decoupling mechanisms observed in other industries. Based upon the assumed similarity, the Solganick Direct then argues that because the adoption of decoupling mechanisms in other industries sometimes results in a reduction in the allowed return on equity that a reduction of 50 basis points is appropriate here.[53] The Solganick Direct provides no evidence that the Companies' new rate design proposal will reduce the Companies' systematic risk, i.e., the risk that affects the cost of capital. It merely asserts that risk will be reduced, but the cost of capital is only affected by changes in *systematic* risk, as described in the Vilbert Direct.[54] Without such evidence of a reduction in systematic risk, a reduction is the cost of equity is not warranted. Second, the Solganick Direct's recommendation is a selective adjustment to one particular class of customers based upon one particular revision in the rate design for that one class of customers without consideration of the totality of the risks for that class of customers compared to the totality of risks for all classes of customers. I believe that such a selective adjustment to the cost of service for one particular class of customers is not warranted and likely to lead to endless debates about the relative risk of one class of customers compared to another. Such selective rate making should be rejected.

Q48. Does the fact that you have not addressed everything discussed in the Adams Direct, the Cahaan Direct, or the Solganick Direct imply that you agree with everything you have not addressed?

A48. No, it does not.

Q49. Does this conclude your Rebuttal Testimony?

A49. Yes.

TABLES AND WORKPAPERS

I. INTRODUCTION AND SUMMARY

Q1. Please state your name and address for the record.

A1. My name is Michael J. Vilbert. My business address is The Brattle Group, 44 Brattle Street, Cambridge, MA 02138, USA.

Q2. Please describe your job and your educational experience.

A2. I am a Principal of The Brattle Group, ("Brattle"), an economic, environmental and management consulting firm with offices in Cambridge, Washington, London, San Francisco and Brussels. My work concentrates on financial and regulatory economics. I hold a B.S. from the U.S. Air Force Academy and a Ph.D. in finance from the Wharton School of Business at the University of Pennsylvania.

Q3. What is the purpose of your testimony in this proceeding?

A3. I have been asked by Virginia Electric and Power Company ("Dominion Virginia Power" or the "Company"), to estimate the cost of equity that the Virginia State Corporation Commission (the "SCC" or the "Commission") should allow Dominion Virginia Power an opportunity to earn on the equity financed portion of its rate base.

To accomplish this task, I estimate the overall cost of capital for a sample of regulated electric companies using the discounted cash flow ("DCF") and the risk positioning models. I then evaluate the relative risk of Dominion Virginia Power compared to the sample companies to determine the recommended cost of equity for a regulatory capital structure with 50.7 percent equity, which is the percentage of equity in Dominion Virginia Power's proposed capital structure in the filing for this proceeding. (By "regulatory capital structure," I mean the capital structures that Dominion Virginia Power utilizes in its application.[1])

[1] The capital structure that I customarily use in these analyses is based upon the long-term sources of capital, i.e., long-term debt, preferred equity and common equity. I do not use short-term debt because long-term assets are not generally financed with short-term debt. This approach is consistent with the information that I use for the sample companies.

Q4. Please summarize the parts of your background and experience that are particularly relevant to your testimony on these matters.

A4. Brattle's specialties include financial economics, regulatory economics, and the gas and electric industries. I have worked in the areas of cost of capital, investment risk and related matters for many industries, regulated and unregulated alike, in many forums. I have testified or filed cost of capital testimony before the Federal Energy Regulatory Commission, the Arizona Corporation Commission, the Pennsylvania Public Utility Commission, the Public Service Commission of West Virginia, the Tennessee Regulatory Authority, the Public Service Commission of Wisconsin, the South Dakota Utilities Board, the Public Utilities Commission of Ohio, the California Public Utilities Board, the Canadian National Energy Board, Alberta Energy and Utilities Board, the Ontario Energy Board, and the Labrador & Newfoundland Board of Commissioners of Public Utilities. I have not previously testified before this Commission. Appendix A contains more information on my professional qualifications.

Q5. Please summarize how you approached this task.

A5. I review the evidence from a sample of regulated electric utilities which were selected to be of comparable business risk to Dominion Virginia Power. My analyses consider cost of capital evidence from the risk positioning and discounted cash flow models, but I rely primarily on the risk positioning results because I do not believe that the DCF method is completely reliable at this time.

Specifically, I estimate the cost of equity for the companies in the sample group using both cost-of-equity estimation methods. For each cost-of-equity estimate, I combine this value with the sample company's market costs of debt and preferred stock to calculate each firm's overall cost of capital, i.e. its after-tax weighted-average cost of capital ("ATWACC"), using each company's market value capital structure as the weights. For each method of estimating the return on equity, I report the sample average ATWACC and the estimated cost of equity for this line of business at a capital structure with 50.7 percent equity. I thus present the cost of equity that is consistent with both the sample's market information and Dominion Virginia Power's regulatory capital structure.

This method automatically avoids problems that can arise when an analyst focuses separately on the individual components (i.e., the cost of equity and the appropriate capital structure) of the overall cost of capital. The danger with that approach is that the estimated cost of equity from the sample may correspond to a very different level of financial risk than would exist at the regulated company's capital structure. The result could be an inconsistency between the allowed return on equity and the financial risk inherent in the regulatory capital structure.

Q6. Why do you believe that the DCF model is less reliable for this industry at this time than the risk positioning model?

A6. Results for the DCF model depend critically on the estimate of the dividend growth rate. A one percent error in the estimate of the growth rate results in a greater than one percent error in the cost of equity estimates. The move toward a restructured industry featuring greater competition among providers of generation services has stalled and the future structure of the electric industry remains in doubt. The legislature in Virginia has approved legislation that effectively ends electric deregulation in the Commonwealth,[2] and the legislature in Illinois proposed a one-year extension of the rate cap on the cost of power that is less than the current market price of power.[3] Natural gas prices have increased dramatically and have been much more volatile lately relative to just a few years ago. Although most of the companies in the sample have fuel cost adjustment clauses, the increased volatility of gas prices has increased the uncertainty of the industry's earnings going forward. These facts are not a description of an industry that could be characterized as stable with earnings and dividends likely to grow at a constant rate over the foreseeable future, but that is precisely the condition necessary for the reliable implementation of the DCF model.

The DCF model results display a greater spread and are more variable and less reliable than those based upon the risk positioning model; however, I provide results using the DCF method, because it is a method that has been relied upon by commissions frequently

[2] H.B. 3068 and S.B. 1416 (commonly called "re-regulation legislation") were approved by the General Assembly on April 4, 2007. See, for example, www.dom.com/about/companies/vapower/rereg.jsp.

in the past. In addition, results from the DCF model serve as a check on the results from the equity risk positioning approach.

Q7. What are the results for the DCF model?

A7. Results from the simple DCF model and for the multistage model are set out in the accompanying tables. (See Table No. MJV-6, Panel A - simple DCF and Panel B - multistage DCF) After properly adjusting for financial risk, the sample average for the simple DCF model is 11.4 percent and for the multistage DCF model is 10.3 percent. (See Table No. MJV-8) I believe that the highly variable DCF results company-to-company displayed in Table No. MJV-7 demonstrate that the conditions necessary for a completely reliable implementation of the DCF model do not obtain at this time.

Q8. What are the results for the risk positioning model?

A8. The sample average risk positioning results, adjusted for differences in financial risk, range from a low of 11.2 to 11.5 percent when using the long-term risk-free rate. The results for the risk positioning model using the short-term risk-free rate range from 11.5 to 12.0 percent, but I place less weight on those estimates in this proceeding. (See Table No. MJV-12)

Q9. You mentioned the importance of considering financial risk when evaluating the results of the models. Please explain how you adjust for financial risk.

A9. Both the DCF and the risk positioning models rely on market data to estimate the cost of equity for the sample companies. That cost of equity estimate captures both the business risk and the financial risk of the assets. Business risk is the risk that the company would have if it were financed entirely with equity. Financial risk is the additional risk carried by the equity holders when debt is used to finance some of the assets. The more debt that is used by a company, the riskier the company's equity becomes. As explained in more detail below, the procedures I use consider both the business risk and the financial risk of the sample companies in comparison to Dominion Virginia Power in determining my recommended cost of equity.

---

[3] See http://www.ilga.gov/legislation/billstatus.asp?DocNum=1750&GAID=9&GA=95&DocTypeID=HB&LegID=30576&SessionID=51

Q10. What is your conclusion on the market-determined cost of capital for Dominion Virginia Power based upon the results from the sample of regulated companies you selected?

A10. As explained more fully below, the best point estimate of the cost of equity for Dominion Virginia Power is 11¾ percent for a capital structure with 50.7 percent equity, but it is more correct to say that the sample results and the risk level of Dominion Virginia Power indicate a range for the cost of equity estimates for the Company from 11¼ to 12¼ percent. The corresponding midpoint of the range of the overall after-tax weighted-average cost of capital estimates, i.e., the ATWACC, for the benchmark sample companies is 8 percent with a range of 7¾ to 8¼ percent. Note, that I specify a plus or minus ½ percent range for the return on equity and specify the point estimate to the nearest ¼ percent because I do not believe that it is possible to estimate the cost of equity more precisely than that.

Q11. How is your testimony organized?

A11. *Section II* formally defines the cost of capital and touches on the principles relating to the cost of capital and capital structure for a business. *Section III* presents the methods used to estimate the cost of capital for the benchmark sample and the associated numerical analyses, and explains the basis of my conclusions for the benchmark sample's returns on equity and overall costs of capital. *Section IV* presents the results of these methods applied to the benchmark sample group, and presents the costs of equity implied by the results. My conclusion on the cost of equity for Dominion Virginia Power is presented in *Section V*. Appendix B provides additional details on the selection of the sample and the calculation of the market value capital structures of the sample companies. Appendices C and D support *Sections III and IV* with additional details on the risk positioning model and DCF approach, respectively, including the details of the numerical analyses. Appendix E discusses the effect of debt on the cost of equity in more detail.

II. COST OF CAPITAL THEORY

A. THE COST OF CAPITAL AND RISK

Q12. Please formally define the "Cost of Capital."

A12. The cost of capital can be defined as *the expected rate of return in capital markets on alternative investments of equivalent risk*. In other words, it is the rate of return investors require based on the risk-return alternatives available in competitive capital markets. The cost of capital is a type of opportunity cost: it represents the rate of return that investors could expect to earn elsewhere without bearing more risk. "Expected" is used in the statistical sense: the mean of the distribution of possible outcomes. The terms "expect" and "expected" in this testimony, as in the definition of the cost of capital itself, refer to the probability-weighted average over all possible outcomes.

The definition of the cost of capital recognizes a tradeoff between risk and return that is known as the "security market risk-return line," or "security market line" for short. This line is depicted in Figure 1. The higher the risk, the higher is the cost of capital. A version of Figure 1 applies for all investments. However, for different types of securities, the location (i.e., the intercept and the slope) of the line may depend on corporate and personal tax rates.

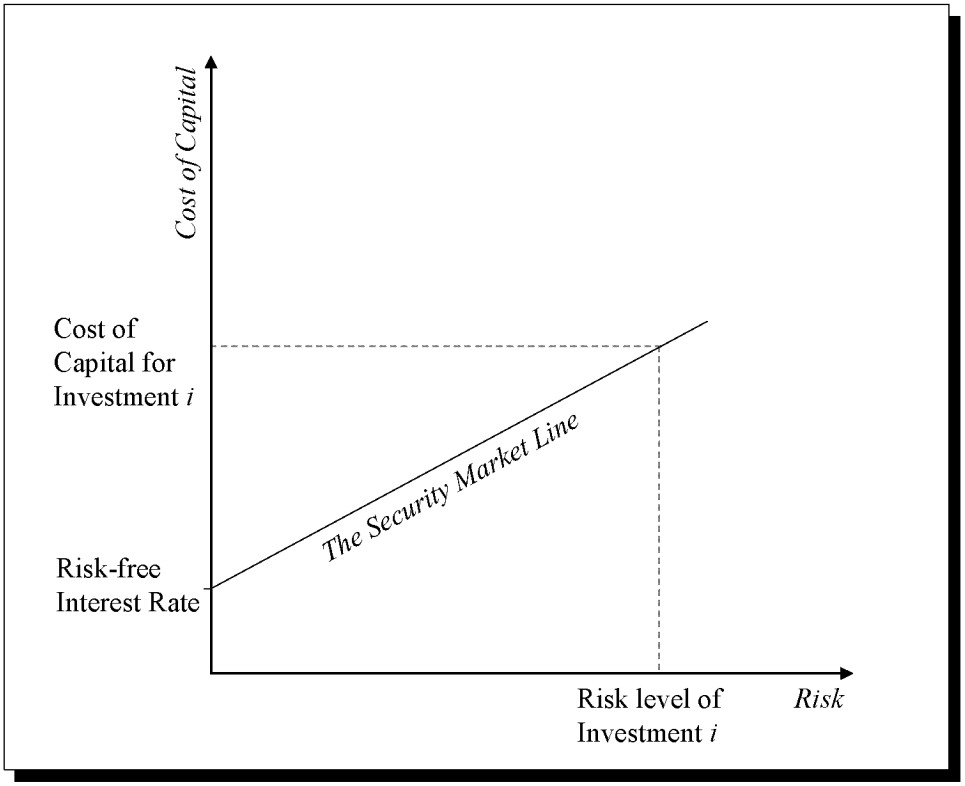

Figure 1: The Security Market Line

Q13. Why is the cost of capital relevant in rate regulation?

A13. It has become routine in U.S. rate regulation to accept the "cost of capital" as the right expected rate of return on utility investment.[4] That practice is normally viewed as consistent with the U.S. Supreme Court's opinions in *Bluefield Waterworks & Improvement Co. v. Public Service Commission*, 262 U.S. 678 (1923), and *Federal Power Commission v. Hope Natural Gas*, 320 U.S. 591 (1944).

From an economic perspective, rate levels that give investors a fair opportunity to earn the cost of capital are the lowest levels that compensate investors for the risks they bear. Over the long run, an expected return above the cost of capital makes customers overpay for service. Regulatory commissions normally try to prevent such outcomes, unless there are offsetting benefits (e.g., from incentive regulation that reduces future costs). At the same time, an expected return below the cost of capital does a disservice not just to

[4] A formal link between the cost of capital as defined by financial economics and the right expected rate of return for utilities is established by Stewart C. Myers, "Application of Finance Theory to Public Utility Rate Cases," *The Bell Journal of Economics and Management Science*, 3:58-97 (Spring 1972).

investors but, importantly, to customers as well. In the long run, such a return denies the company the ability to attract capital, to maintain its financial integrity, and to expect a return commensurate with that of other enterprises attended by corresponding risks and uncertainties.

More important for customers, however, are the economic issues an inadequate return raises for them. In the short run, deviations of the expected rate of return on the rate base from the cost of capital may seemingly create a "zero-sum game"-- investors gain if customers are overcharged, and customers gain if investors are shortchanged. But in fact in the short run, such action may adversely affect the utility's ability to provide stable and favorable rates because some potential efficiency investments may be delayed or because the company is forced to file more frequent rate cases. In the long run, inadequate returns are likely to cost customers -- and society generally -- far more than is gained in the short run. Inadequate returns lead to inadequate investment, whether for maintenance or for new plant and equipment. The costs of an undercapitalized industry can be far greater than the short-run gains from shortfalls in the cost of capital. Moreover, in capital-intensive industries (such as the electric utility industry), systems that take a long time to decay cannot be fixed overnight. Thus, it is in the customers' interest not only to make sure the return investors expect does not exceed the cost of capital, but also to make sure that it does not fall short of the cost of capital, either.

Of course, the cost of capital cannot be estimated with perfect certainty, and other aspects of the way the revenue requirement is set may mean investors expect to earn more or less than the cost of capital even if the allowed rate of return equals the cost of capital exactly. However, a commission that sets rates so investors expect to earn the cost of capital on average treats both customers and investors fairly, and acts in the long-run interests of both groups.

Q14. If a regulator sets the allowed return equal to the cost of capital is that sufficient to insure that the regulated company has a fair opportunity to earn its cost of capital?

A14. In general, yes, but there are circumstances in which it would not. Specifically, if the regulated company faces a substantial level of asymmetric risk, the regulated company

may not expect to earn its cost of capital on average. Asymmetric risk for a regulated company exists when the possibility of a large negative outcome is not balanced by the possibility of a corresponding positive outcome. For example, if a regulated electric distribution company serving as provider of last resort ("PoLR") were unable to pass through to customers the full costs of acquiring power due a rate cap, setting the allowed return equal to the cost of capital would not provide a fair opportunity to earn it. This is the situation currently faced by the utilities in Illinois with the proposed extension of a price cap that is less than the current price of power. In such a situation, the regulated company will expect to earn less than its cost of capital if there is any possibility that the market cost of power exceeds the rate cap. The solution would be to either remove the source of the asymmetric risk (e.g., the price cap) or set the allowed return high enough so that the regulated company can again expect to earn its cost of capital.

Q15. Does asymmetric risk affect the cost of capital?

A15. Maybe. In general, asymmetric risk definitely affects the probability that a regulated utility would expect to earn its allowed return, but it may not affect its cost of capital. The cost of capital would be affected only if the asymmetric risk were correlated with changes in the capital market. However, if a regulated utility faces substantial asymmetric risk, the allowed return on equity would have to be increased in order for the regulated company to expect to earn its cost of capital on average.

Q16. Please expand the discussion how a regulator can correct the effect of asymmetric risk?

A16. There are two ways to correct asymmetric risk. The first is to add a premium to the allowed rate of return on equity for the regulated company so that it can again expect to earn its cost of capital. The second method is to remove the source of the asymmetric risk which in this example means allowing full recovery of the cost of providing PoLR service to the regulated company's customers. I believe that removing the source of the asymmetric risk is a more efficient and cost effective way to establish the conditions necessary for the regulated company to expect to earn its cost of capital.

Q17. Is this an issue for Dominion Virginia Power at this time?

A17. Perhaps. There are aspects of the re-regulation legislation that are asymmetric in that the Company could be treated differently in generally similar circumstances. For example, if the Company were to earn more than its allowed return by more than 50 basis points ("bps"), it may be required to refund up to 60 percent of the amount greater than 50 bps. On the other hand, if the Company were to earn less than its allowed return by more than 50 bps, there is no additional recovery of the amount of the shortfall comparable to the repayment of the amount of earnings greater than 50 bps. Effectively, this provision imposes the downside on the Company, but takes away a portion of the upside in earnings.

Q18. Does your recommended return in this proceeding include any increase as compensation for asymmetric risk in the re-regulation legislation?

A18. No.

B. Business Risk & Financial Risk: Capital Structure and the Cost of Equity

Q19. Please explain briefly the difference between business risk and financial risk.

A19. Business risk is the risk of a company from its line of business if it used no debt financing. When a firm uses debt to finance its assets, the business risk of the assets is shared between the debt holders and the equity holders, but the equity holders bear more of the risk because debt holders have a prior claim on the company's cash flows. Equity holders are residual claimants, which simply means that equity holders get paid last. In other words, the use of debt imposes financial risk on the equity holders. Therefore, the goal of selecting a sample is to choose companies whose business risk is judged to be comparable to Dominion Virginia Power.

Q20. Please explain why it is necessary to report the cost of equity adjusted for capital structure.

A20. Briefly, rate regulation in North America tends to focus on the components of the overall cost of capital, and in particular, on what the "right" cost of equity and capital structure

should be. Frequently, there is no consideration of whether the financial risks of the sample companies differ among themselves or differ from the regulated company. The cost of equity estimated using the standard models (e.g., the DCF model or the risk positioning model) reflects both the business and financial risk of the sample companies. However, the overall cost of capital depends primarily on the business the firm is in, i.e., business risk, while the costs of the debt and equity components depend not only on this business risk alone but also on the distribution of revenues between debt and equity, i.e. financial risk. The overall cost of capital is thus the more basic concept. As I explain in Appendix E, the overall cost of capital is constant within a broad middle range of values of capital structures, but the distribution of the costs and risks among debt and equity is not. Appendix E sets out the principles and procedures on which I rely.

C. IMPLICATIONS FOR ANALYSIS

Q21. Please explain the implications of the relationship between capital structure and the cost of equity in your testimony.

A21. The risk equity holders carry, and therefore the cost of equity, depends on the capital structure. As leverage increases, financial risk increases, and hence the required return on equity increases. An approach that estimates the cost of equity for each of the sample firms without explicit consideration of the market value capital structure (i.e., the financial risk) underlying those costs risks material errors. The costs of equity of the sample companies at their actual market-value capital structures do not necessarily reflect the same degree of financial risk as faced by equity holders in the regulated company, and thus could lead to an unfair rate of return if the sample's cost of equity estimate were simply and mechanically applied to the regulated company's capital structure. I avoid this problem by calculating each sample company's ATWACC using its market value capital structure. Using the sample's average overall cost of capital (i.e., the average of the sample companies' ATWACCs) as an estimate of Dominion Virginia Power's cost of capital, I then determine the corresponding return on equity at Dominion Virginia Power's filed regulatory capital structure as sponsored by Company Witness M. Stuart Bolton, Jr. This procedure ensures that the capital structure (i.e., financial risk) and the estimated cost of equity are consistent with the market derived sample information.

In the following analyses, I estimate the cost of equity for each of the sample firms using the DCF and risk positioning estimation methods. I use each company's estimated cost of equity along with Dominion Virginia Power's estimated 2008 marginal tax rate and each sample company's cost of debt and market-value capital structure to estimate the company's overall cost of capital.[5] I then calculate the sample's average overall cost of capital for each equity estimation method. Using the procedure discussed above, I then determine the cost of equity at Dominion Virginia Power's regulated capital structure that is consistent with the sample's overall cost of capital information for each estimation method.

Q22. To assess the magnitude of financial risk for a rate regulated company, should you use the market-value or the book-value capital structure?

A22. The market-value capital structure is the relevant quantity for analyzing the cost of equity evidence, which is based on market information.

Q23. Has the need to use market-value capital structures to estimate the cost of equity been widely recognized in the academic community?

A23. Yes. The need to use market-value capital structures to analyze the effect of debt on the cost of equity has been recognized in the financial literature for a long time. For example, the initial reconciliation of the Modigliani-Miller theories of capital structure with the Capital Asset Pricing Model, in Robert S. Hamada, "Portfolio Analysis, Market Equilibrium and Corporate Finance," The Journal of Finance 24: 13-31 (March 1969) works with market-value capital structures. For a more recent presentation of the concept, see, for example, Richard A. Brealey, Stewart C. Myers, and Franklin Allen, *Principles of Corporate Finance*, New York: McGraw-Hill/Irwin 8th ed. (2006) pp. 503-06. Book values may be relevant for some issues, e.g., for covenants on individual bond issues, but as explained in the text, market values are the determinants of the impact of debt on the cost of equity.

[5] The marginal tax rate was provided by the Company.

Q24. Is the use of market values to calculate the impact of capital structure on the risk of equity incompatible with use of a book-value rate base for a regulated company?

A24. No, no more than it is incompatible to use market-based cost of equity estimation methods (such as DCF or the risk positioning model) with a book-value rate base. That is, the cost of capital is the fair rate of return on regulatory investment (i.e., rate base) for both investors and customers. Most regulatory jurisdictions in North America measure the rate base using the net book value of assets, not current replacement value or historical cost trended for inflation, but the jurisdictions still apply market-derived measures of the cost of equity to that net book-value rate base.

The issue here is "what level of risk is reflected in that cost of equity estimate?" That equity risk level depends on the sample company's market-value capital structure, not its book-value capital structure. *That risk level would be different if the sample company's market-value capital structure exactly equaled its book-value capital structure, so the estimated cost of equity would be different, too.*

Q25. Please sum up the implications of this section.

A25. The market risk, and therefore the cost of equity, depends directly on the market-value capital structure of the company or asset in question. It therefore is impossible to compare validly the measured costs of equity of different companies without taking capital structure into account. Capital structure and the cost of equity are unbreakably linked, and any effort to treat the two as separate and distinct questions violates both everyday experience (e.g., with home mortgages as shown in the extended example in Appendix E) and basic financial principles.

Q26. How should a cost of capital analyst implement this principle?

A26. As discussed further in Appendix E, there has been a great deal of financial research on the effects of capital structure on the value of the firm. One of the key conclusions that results from the research is that no narrowly defined optimal capital structure exists within industries, although the typical range of capital structures does vary among

industries.[6] Instead, there is a relatively wide range of capital structures within any industry in which fine-tuning the debt ratio makes little or no difference to the value of the firm, and hence to its overall after-tax cost of capital.

Accordingly, analysts should treat the market-value weighted average of the cost of equity and the after-tax current cost of corporate debt, or the "ATWACC" for short,[7] as constant within a broad middle range of capital structures for the industry. Sample evidence should be analyzed to determine the sample's average ATWACC, which can be compared across different firms or industries. The economically appropriate cost of equity for a regulated firm is the quantity that, when applied to the *regulatory* capital structure, produces the same ATWACC. That value is the cost of equity that the sample would have had, estimation problems aside, if the sample's market-value capital structure had been equal to the regulatory capital structure in question.

Q27. Can you provide an example of the calculation of the cost of equity consistent with the market-determined estimate of the sample's average overall cost of capital?

A27. Yes. Consider the following equation to calculate the ATWACC:[8]

$$ATWACC = r_D \times (1 - T_C) \times D + r_E \times E \quad (1)$$

where r_D = market cost of debt,
r_E = market cost of equity,
T_C = corporate marginal income tax rate,
D = percentage of debt in the capital structure, and
E = percentage of equity in capital structure.

[6] An exception is that very high-risk industries should avoid debt entirely, which makes their optimal capital structure zero percent debt.

[7] This quantity typically is called the "weighted-average cost of capital" or "WACC" in finance textbooks. The textbook WACC equals the *market*-value weighted average of the cost of equity and the *after-tax*, *current* cost of debt. However, rate regulation in North America has a legacy of working with another, and very different, weighted-average cost of capital, the *book*-value weighted average of the cost of equity and the *before-tax*, *embedded* cost of debt. Accordingly, in regulatory settings it's useful to refer to the textbook WACC as the "ATWACC," or "after-tax weighted-average cost of capital." I follow that practice here.

[8] Note that this equation assumes that only debt and equity are in the capital structure, but one can add preferred equity to the equation if appropriate.

The cost of equity consistent with overall cost of capital estimate (ATWACC), the market cost of debt and equity, the marginal corporate income tax rate and the amount of debt and equity in the capital structure can be determined by solving equation (1) for r_E.

III. COST OF CAPITAL METHODOLOGY

Q28. How is this section of your testimony organized?

A28. As noted in Section II, I estimate the cost of capital using a sample of comparable risk companies. This section first outlines the steps involved in selecting the benchmark sample, in determining the market-value capital structures, and in estimating the sample companies' costs of debt. It then turns to the procedures for estimating the cost of equity and describes the two cost of equity estimation methodologies used in this testimony, the DCF method and the risk positioning approach. These are the foundations of my cost of capital calculations which I present in the following section and which I use to derive a recommended cost of equity for Dominion Virginia Power at its regulatory capital structure.

A. SAMPLE SELECTION

Q29. How do you select the benchmark sample of regulated electric utilities?

A29. The overall cost of capital for a part of a company depends on the risk of the business in which the part is engaged, not on the overall risk of the parent company on a consolidated basis. According to financial theory, the overall risk of a diversified company equals the market-value-weighted average of the risks of its components.

Estimating the cost of capital for Dominion Virginia Power's SCC regulated assets is the subject of this proceeding. Normally, the ideal sample would be a number of publicly traded "pure play" integrated electric companies or perhaps electric distribution companies with a PoLR responsibility. "Pure Play" is an investment term referring to companies with operations only in one line of business. Publicly traded firms, firms whose shares are freely traded on stock exchanges, are ideal because the best way to infer the cost of capital is to examine evidence from capital markets on companies in the given line of business.

Currently, Dominion Virginia Power is a regulated distribution and transmission company with a PoLR responsibility, but the re-regulation legislation noted earlier will alter the Company's status. A limited PoLR obligation, subject to conditions set forth in the restructuring legislation, will remain after December 31, 2008 for the larger customers with a load of 5 MW or more, or for certain aggregation customers, but most small consumers will no longer be able to choose retail access. As a regulated utility in a partially deregulated state that is transitioning to a fully integrated electric utility, Dominion Virginia Power's current situation is unique. As a result, I selected a sample of 15 companies whose operations are concentrated in the regulated portions of the electric industry. Some of the sample companies are integrated electric utilities in traditionally regulated states and some are transmission and distribution electric utilities in deregulated states. To select the sample, I start with the companies listed as electric utilities in *Value Line*. I then apply my standard selection procedures which require, for example, that data from S&P or Moody's, *Value Line*, I/B/E/S and Bloomberg be available for all sample companies. Moreover, the companies must have a high percentage of regulated electric utility assets, no significant merger activity in the previous five years, and no recent dividend cuts or other activity that could cause the growth rates or beta estimates to be biased.

Q30. Does your sample differ from the one used by Company Witness Bolton?

A30. Yes. Mr. Bolton selected the peer group sample by reference to the direction contained in the re-regulation legislation. The legislation restricts the sample geographically and requires the peer group companies to be integrated electric utilities with an investment grade credit rating from Moody's. The companies in the peer group do not have traded stock, but this is not a problem for the cost of equity estimation technique encompassed in the legislation. The cost of equity is estimated in a manner similar to a comparable earnings approach in which the sample companies' realized accounting return on book equity is used as a benchmark.

Q31. Why didn't you select your sample companies using the same set of critera?

A31. I did employ some similar criteria such as restricting the sample to investment grade companies, but implementation of the DCF and risk positioning models requires that the

sample companies have traded stock so it is impossible to use the same peer group sample. There is a tradeoff between selecting companies that are close to pure plays in the electric utility industry and finding companies with traded stock. The peer group consists of companies that are more nearly pure plays in the electric industry compared to my sample which generally consists of holding companies. On the other hand, the peer group estimates make no use of market information such as capital gains or losses and dividend payments or market measures of risk.

Q32. Please summarize your comparison of the peer group approach and your approach to estimating the cost of equity for the Company.

A32. The two approaches are complementary in that they attempt to estimate the cost of equity for the Company using different information sets. The peer group approach can be more restrictive in company selection because it is not restricted to companies with traded stock and uses accounting information. My approach relies upon market information, but requires traded stock. Because there are fewer companies with traded stock from which to choose, I include companies in the sample that would have been eliminated had I applied the same restrictions as required by the legislation, resulting in a very small sample. The problem would have been exacerbated by the legislation's requirement to drop the two highest and two lowest estimates.

B. CAPITAL STRUCTURE & THE COST OF DEBT

1. Market-Value Capital Structure

Q33. What capital structure information do you require?

A33. For reasons discussed in Appendix E, explicit evaluation of the market-value capital structures of the sample companies is vital for a correct interpretation of the market evidence on the return on equity. This requires estimates of the market values of common equity, preferred equity and debt, and the current market costs of preferred equity and debt.

Q34. Please describe how you calculate the market values of common equity, preferred equity and debt.

A34. I estimate the capital structure for each sample company by estimating the market values of common equity, preferred equity and debt from the most recent publicly available data. The details are in Appendix B.

Briefly, the market value of common equity is the price per share times the number of shares outstanding. For the risk positioning approach, I use the last five trading days of each year to calculate the market value of equity for the year. I then calculate the average capital structure over the corresponding five-year period used to estimate the "beta" risk measures for the sample companies.[9] This procedure matches the estimated beta to the degree of financial risk present during its estimation period. In the DCF analyses, I use the average closing stock price over the 15 trading days ending on the day that the earnings growth rate forecasts are obtained from Bloomberg.[10]

The market value of debt is estimated at its book value adjusted by the difference between the "estimated fair (market) Value" and the "carrying cost" of long-term debt reported in each company's 10-K.[11] The market value of preferred stock for the samples is set equal to its book value because the percent of preferred stock in the capital structures of the sample companies is relatively small compared to the debt and common equity components.

2. Market Costs of Debt and Preferred Equity

Q35. How do you estimate the current market cost of debt?

A35. The fifteen-day average market cost of debt for each company is set equal to the yield on an index of public utility bonds that have the same credit rating, and the yield is reported by Bloomberg's for an index of public utility company bonds with the same S&P

[9] *Value Line* uses five years of historical data to estimate its forecasted betas.

[10] Forecasts were obtained on June 11, 2007 for all companies in the benchmark sample.

[11] The book value of debt from Bloomberg includes all interest-bearing financial obligations that are not current and includes capitalized leases and mandatory redeemable preferred and trust preferred securities in accordance with FASB 150 effective June 2003. See Bloomberg definition of long-term debt for additional detail.

rating.[12] The DCF analyses use the current credit rating whereas the risk positioning analyses use the current yield of a utility bond that corresponds to the five-year average debt rating of each company so as to match consistently the horizon of information used by *Value Line* to estimate company's beta.

Q36. How do you estimate the market cost of preferred equity?

A36. For each company with preferred stock, the cost of preferred equity for each company is set equal to the yield on an index of preferred stock as reported in the Mergent Bond Record[13] corresponding to the S&P rating of that company's debt.

3. Risk-Free Interest Rate Forecast

Q37. What is the risk-free rate?

A37. The risk-free rate is the interest rate that can be earned with certainty. A common measure of this rate is the return on the government's Treasury bills and bonds. This rate is usually significantly below the rate which other borrowers pay for debt.

Q38. How do you obtain the forecasts of the risk-free interest rates over the period the utility rates set here are to be in effect?

A38. I obtain these forecast rates using data provided by Bloomberg. In particular, I use the reported government debt yields from the "constant maturity series". This information is displayed in Panels A and B of Table No. MJV-9.

Q39. What values do you use for the short-term and long-term risk-free interest rates?

A39. I use a value of 5.1 percent for the long-term risk-free interest rate as the benchmark risk-free interest rates in the equity risk premium analyses and a value of 4.1 percent for the short-term risk-free interest rate. The short-term rate is derived by using historical yield curve data to find the long-run average implied term premia on government securities,

[12] See Workpaper #2, Panel A to Table No. MJV-11.

[13] Published monthly, *Mergent's Bond Record* offers a comprehensive review of over 68,000 bond issues including coverage of corporate, government, municipal, industrial development/environmental control revenue and international bonds, plus structured finance and equipment trust issues, medium-term notes, convertible issues, preferred stocks and commercial paper issues.

and combining these with recent yield curve data. Details of their calculation can be found in the Workpapers to Table No. MJV-9.

C. Cost of Equity Methods

Q40. How do you estimate the cost of equity for your sample companies?

A40. Recall the definition of the cost of capital from the outset of my testimony: the expected rate of return in capital markets on alternative investments of equivalent risk. My cost of capital estimation procedures address three key points implied by the definition:

1. Since the cost of capital is an expected rate of return, it cannot be directly observed; it must be inferred from available evidence.

2. Since the cost of capital is determined in capital markets (e.g., the New York Stock Exchange), data from capital markets provide the best evidence from which to infer it.

3. Since the cost of capital depends on the return offered by alternative investments of equivalent risk, measures of the risks that matter in capital markets are part of the evidence that needs to be examined.

Q41. How does the above definition help in cost of capital estimation?

A41. The definition of the cost of capital recognizes a tradeoff between risk and expected return, plotted above in Figure 1, the security market line. Cost of capital estimation methods take one of two approaches: (1) they try to identify a comparable-risk sample of companies and to estimate the cost of capital directly; or (2) they establish the location of the security market line and estimate the relative risk of the security, which jointly determine the cost of capital. In terms of Figure 1, the first approach focuses directly on the vertical axis, while the second focuses both on the security's position on the horizontal axis and on the position of the security market line.

The first type of approach is more direct, but ignores the wealth of information available on securities not thought to be of precisely comparable risk. The "discounted cash flow" or "DCF" model is an example. The second type of approach, sometimes known as "equity risk premium approach," requires an extra step, but as a result can make use of information on all securities, not just a very limited subset. The Capital Asset Pricing

Model ("CAPM") is an example. While both approaches can work equally well if conditions are right, one may be preferable to the other under a given set of circumstances. In particular, approaches that rely on the entire security market line (e.g., the risk positioning model) are less sensitive to deviations from the assumptions that underlie the model, all else equal. In this proceeding, I examine sample evidence from both the DCF and risk positioning models.

1. The Risk Positioning Approach

Q42. Please explain the risk positioning method.

A42. The risk positioning method estimates the cost of equity as the sum of a current interest rate and a company specific risk premium. It is therefore sometimes also known as the "risk premium" approach. This approach may sometimes be applied informally. For example, an analyst or Commission may check the spread between interest rates and what is believed to be a reasonable estimate of the cost of capital at one time, and then apply that spread to changed interest rates to get a new estimate of the cost of capital at another time.

More formal applications of the risk positioning approach take full advantage of the security market line depicted in Figure 1: they use information on all securities to identify the security market line and derive the cost of capital for the individual security based on that security's relative risk. This reliance on the entire security market line makes the method less vulnerable to the kinds of problems that arise for the DCF method, which relies on one stock at a time. The risk positioning approach is widely used and underlies most of the current research published in academic journals on the nature, determinants and magnitude of the cost of capital.

Section I of Appendix C to this testimony provides more detail on the principles that underlie the risk positioning approach. Section II of Appendix C provides the details of the risk positioning approach empirical estimates I obtain.

Q43. How are the "more formal" applications of risk positioning approach implemented?

A43. The first step is to specify the current values of the parameters that determine the security market line. The second is to determine the security's or the investment's relative risk. The third is to specify exactly how the parameters combine to produce the security market line, so the company's cost of capital can be calculated based on its relative risk. All of these elements and how they relate are usefully formulated in the framework of the CAPM.

a) The Capital Asset Pricing Model

Q44. Please start with the CAPM, by describing the model.

A44. As noted above, the modern models of capital market equilibrium express the cost of equity as the sum of a risk-free rate and a market risk premium. The CAPM is the longest-standing and most widely used of these theories. The CAPM states that the cost of capital for an investment, *s*, (e.g., a particular common stock) is given by the following equation:

$$k_s = r_f + \beta_s \times MRP \qquad (2)$$

where k_s is the cost of capital for investment *s*; r_f is the risk-free rate, β_s is the beta risk measure for the investment *s*; and *MRP* is the market risk premium.

The CAPM relies on the empirical fact that investors price risky securities to offer a higher expected rate of return than safe securities do. It says that the security market line starts at the risk-free interest rate (that is the return on a zero-risk security, the y-axis intercept in Figure 1, equals the risk-free interest rate). It further says that the risk premium over the risk-free rate equals the product of beta and the risk premium on a value-weighted portfolio of all investments, which by definition has average risk.

b) The Empirical Capital Asset Pricing Model

Q45. What other equity risk premium model do you use?

A45. Empirical research has long shown that the CAPM tends to overstate the actual sensitivity of the cost of capital to beta: low-beta stocks tend to have higher risk premia than predicted by the CAPM and high-beta stocks tend to have lower risk premia than predicted. A number of variations on the original CAPM theory have been proposed to explain this finding, but this finding can also be used to estimate the cost of capital directly, using beta to measure relative risk without simultaneously relying on the CAPM.

The second model makes use of these empirical findings. It estimates the cost of capital with the equation, where α is the "alpha" adjustment of the risk-return line, a constant,

$$k_s = r_f + \alpha + \beta_s \times (MRP - \alpha) \quad (3)$$

and the other symbols are defined as above. I label this model the Empirical Capital Asset Pricing Model, or "ECAPM." The alpha adjustment has the effect of increasing the intercept but reducing the slope of the security market line in Figure 1, which results in a security market line that more closely matches the results of empirical tests.

Q46. Why is it appropriate for you to use the empirical CAPM?

A46. Although the CAPM is still the most widely used cost of capital estimation model, it has not been completely satisfactory as an empirical model; however, its short-comings are directly addressed by the ECAPM. The ECAPM recognizes the consistent empirical observation that the CAPM underestimates (overestimates) the cost of capital for low (high) beta stocks. In other words, the ECAPM is based on the recognition that the actual slope of the risk-return tradeoff is flatter than predicted and the intercept higher based upon repeated empirical tests of the CAPM. The alpha parameter (α) in the ECAPM adjusts for this fact. The difference between the CAPM and the type of relationship identified in the empirical studies is depicted in Figure 2.

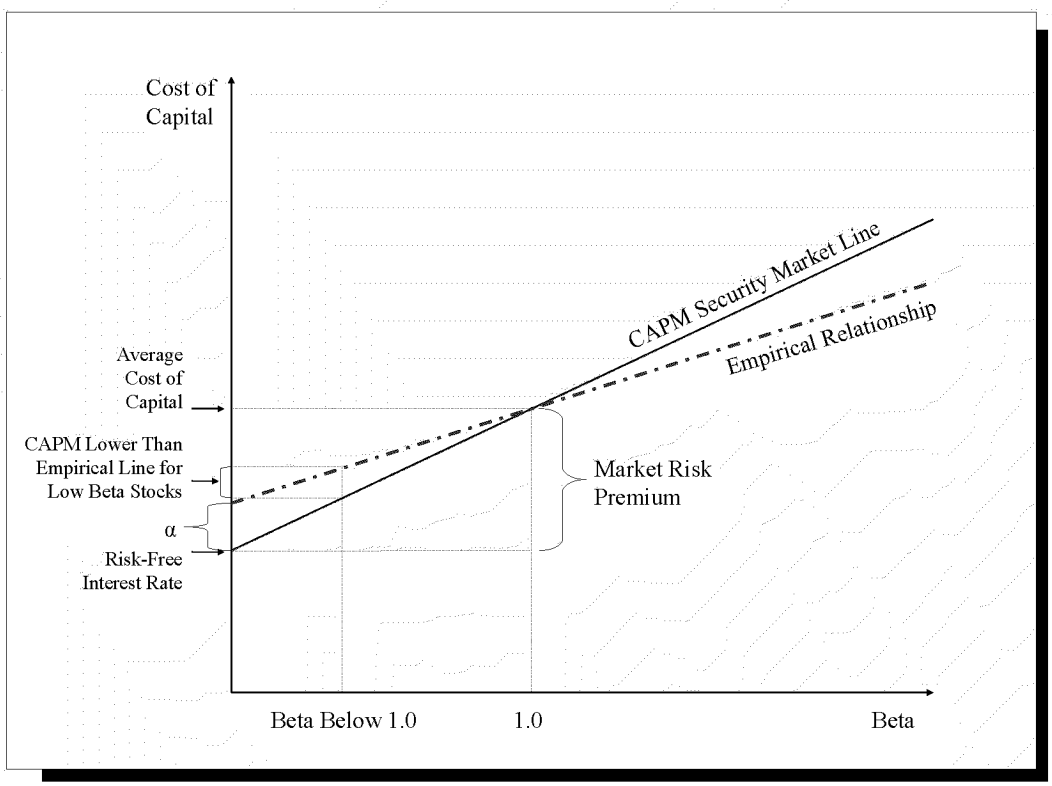

Figure 2: The Empirical Security Market Line

Research supports values for α of one to seven percent when using a short-term interest rate. I use baseline values of α of 2 percent for the short-term risk-free rate and 0.5 percent for the long-term risk-free rate. I also conduct sensitivity tests for different values of α. For the short-term risk-free rate I use values for α of 1, 2 and 3 percent. These α values are lower than would be justified by the magnitude of the correction revealed in the tests of the CAPM. For the long-term risk-free rate, the corresponding values for α are 0, 0.5 and 1.5 percent. The use of a long-term risk-free rate incorporates some of the desired effect of using the ECAPM. That is, the long-term risk-free rate version of the security market line has a higher intercept and a flatter slope than the short-term risk-free version which has been extensively tested. Thus, I do not need to make the same degree of refinement when I use the long-term risk-free rate. Please see Table No. MJV-C1 in Appendix C for a summary of the empirical evidence on the size of the required adjustment necessary to better match the results of the empirical tests.

2. Discounted Cash Flow Method

Q47. Please describe the discounted cash flow approach.

A47. The DCF model takes the first approach to cost of capital estimation, i.e., to attempt to estimate the cost of capital in one step. The method assumes that the market price of a stock is equal to the present value of the dividends that its owners expect to receive. The method also assumes that this present value can be calculated by the standard formula for the present value of a cash flow stream:

$$P = \frac{D_1}{(1+k)} + \frac{D_2}{(1+k)^2} + \frac{D_3}{(1+k)^3} + \cdots + \frac{D_T}{(1+k)^T} \quad (4)$$

where "P" is the market price of the stock; "D_t" is the dividend cash flow expected at the end of period t (i.e., subscript period 1, 2, 3 or T in the equation); "k" is the cost of capital; and "T" is the last period in which a dividend cash flow is to be received. The formula just says that the stock price is equal to the sum of the expected future dividends, each discounted for the time and risk between now and the time the dividend is expected to be received.

Very often, when the DCF is applied in regulatory proceedings, very strong (i.e., unrealistic) assumptions are used that yield a simplification of the standard formula, which then can be rearranged to estimate the cost of capital. Specifically, it is assumed that investors expect a dividend stream that will grow *forever* at a steady rate, and if so, the market price of the stock will be given by a very simple formula,

$$P = \frac{D_1}{(k-g)} \quad (5)$$

where "D_1" is the dividend expected at the end of the first period, "g" is the perpetual growth rate, and "P" and "k" are the market price and the cost of capital, as before. Equation (5) is a simplified version of equation (4) that can be solved to yield the well known "DCF formula" for the cost of capital:

$$k = \frac{D_1}{P} + g$$
$$= \frac{D_0 \times (1+g)}{P} + g \qquad (6)$$

where "D_0" is the current dividend, which investors expect to increase at rate g by the end of the next period, and the other symbols are defined as before. Equation (6) says that if equation (5) holds, the cost of capital equals the expected dividend yield plus the (perpetual) expected future (forever constant) growth rate of dividends. I refer to this as the simple DCF model. Of course, the "simple" model is simple because it relies on very strong (i.e., very unrealistic) assumptions.

Q48. Are there other versions of the DCF models besides the "simple" one?

A48. Yes. The constant growth rate DCF model requires that dividends and earnings grow at the same rate for companies that earn their cost of capital on average.[14] It is inconsistent with the theory on which the model is based to have different growth rates in earnings and dividends over the period when growth is assumed to be constant. If the growth in dividends and earnings were expected to vary over some number of years before settling down into a constant growth period, then it would be appropriate to estimate a multistage DCF model. In the multistage model, earnings and dividends can grow at different rates, but must grow at the same rate in the final, constant growth rate period. A difference between forecasted dividend and earnings rates therefore is a signal that the facts do not fit the assumptions of the simple DCF model.

So, I consider a variant of the DCF model that relies on slightly less strong assumptions in that it allows for varying dividend growth rates in the near term before assuming a perpetual growth rate beginning in year eleven. I use the forecast growth of GDP as the forecast of the long-term growth rate, i.e. year eleven on. This is a "multistage" variant

[14] Why must the two growth rates be equal in a steady-growth DCF model? Think of earnings as divided between reinvestment, which funds future growth, and dividends. If dividends grow faster than earnings, there is less investment and slower growth each year. Sooner or later dividends will equal earnings. At that point, growth is zero because nothing is being reinvested (dividends are constant). If dividends grow slower than earnings, each year a bigger fraction of earnings are reinvested. That makes for ever faster growth. Both scenarios contradict the steady-growth assumption. So if you observe a company with different expectations for dividend and earnings growth, you know the company's stock price and its dividend growth forecast are inconsistent with the assumptions of the steady-growth DCF model.

of the DCF method. The DCF models are described in detail in Section I.A of Appendix D. (Section II of Appendix D provides the details of my empirical DCF results.)

Q49. What are the merits of the DCF approach?

A49. The DCF approach is conceptually sound if its assumptions are met, but can run into difficulty in practice because those assumptions are so strong[15], and hence so unlikely to correspond to reality. Dividends, earnings and prices are unlikely to grow at a constant rate literally forever. Two conditions are also well known to be necessary for the DCF approach to yield a reliable estimate of the cost of capital: the variant of the present value formula that is used must actually match the variations in investor expectations for the growth of dividends, and the growth rate(s) used in that formula must match current investor expectations. Less frequently noted conditions may also create problems (see Appendix D for details).

Q50. Is estimating the "right" dividend growth rate the most difficult part for the implementation of the DCF approach?

A50. Yes. Finding the right growth rate(s) is the usual "hard part" of a DCF application. The original approach to estimation of *g* relied on average historical growth rates in observable variables, such as dividends or earnings, or on the "sustainable growth" approach, which estimates *g* as the average book rate of return times the fraction of earnings retained within the firm. But it is highly unlikely that these historical averages over periods with widely varying rates of inflation and costs of capital will equal current growth rate expectations. As discussed above, this is particularly true for the electric industry at present because the ultimate structure of the industry is uncertain. The movement toward restructuring nationwide has stalled and, in Virginia the restructuring process is being reversed. Similar proposal are under consideration other locations. In addition, there is uncertainty associated with the possible imposition of new environmental regulations and the effect of the relatively rapid increase in fuel prices. These facts are not a description of the stable conditions necessary for the reliable implementation of the DCF model.

[15] In this context "strong" means that the assumption is unlikely to match reality and that it also has a substantial impact on the model's results.

IV. DOMINION VIRGINIA POWER's COST OF CAPITAL

A. DOMINION VIRGINIA POWER'S OPERATIONS AND RISKS

Q51. Please describe the operating characteristics of Dominion Virginia Power.

A51. Dominion Virginia Power is a regulated public utility that serves 2.4 million customers in Virginia and northeastern North Carolina. Currently rates are unbundled cost-based rates for distribution and transmission. Dominion Virginia Power owns generation assets but total rates are capped at 1999 levels until December 31, 2008.[16] Currently, the Company is a net importer of power. Retail choice has been available in Virginia since January 1, 2003; however, to date competition in Virginia has not developed to any significant extent.[17] Dominion Virginia Power's fuel adjustment clause was revised in June 2007 to change the way the fuel factor is set beginning on July 1, 2007. Deferred fuel costs are to be recovered over a 3½ period beginning July 1, 2007 with no interest received on deferred balances. Dominion Virginia Power is a member of PJM Interconnection, LLC ("PJM") and has integrated its electric transmission facilities in the PJM wholesale electricity markets.

B. SAMPLE SELECTION

Q52. How did you select your sample of electric utilities?

A52. The goal was to create a sample of companies whose primary business is as a regulated electric utility with business risk generally similar to that of Dominion Virginia Power. To construct this sample, I started with a universe of 68 companies by combining the electric companies under East, Central and West electric utility categories listed in *Value Line*.[18] From this group companies were first eliminated if their operating regions were outside of the continental USA or if they were primarily engaged in generation and/or transmission. I then applied my standard selection criteria outlined earlier to remove companies without sufficient data to estimate their cost of capital, companies showing

[16] This was changed from December 31, 2010 by the re-regulation legislation.

[17] See Dominion Resources Form 10-K, December 31, 2006, p. 4.

[18] These three categories include all companies followed by *Value Line* that are classified as electric utilities.

signs of financial distress (i.e. less than an investment grade credit rating from S&P), with large recent merger and acquisition ("M&A") activity, recent dividend cuts, companies with a small market capitalization, and companies whose share of regulated assets was estimated to be less than 50 percent.

Specifically, I required the sample companies to have an investment grade credit rating (i.e., BBB- or above), have had no dividend cuts in the past five years, have revenues of at least $300 million and have five years of historical data in Bloomberg. I also required that the companies have engaged in no major merger or acquisition during the last five years. A total of 15 companies met all of these requirements: Cleco Corp, Consolidated Edison, DTE Energy, Empire District Electric, Entergy Corp, FirstEnergy Corp, MGE Energy, NSTAR, Pinnacle West Capital Corp, Otter Tail Corp., PPL Corp, Puget Energy, Southern Co., and SCANA. Details on the sample selection process are in Appendix B. Characteristics of the sample companies are outlined in Table 1 below.

Table 1: Benchmark Electric Sample

Company	Revenue (2006) ($MM) [1]	Regulated Electric Assets [2]	Market Cap. (2006) ($MM) [3]	S&P Bond Rating (2007) [4]	Beta [5]	Long-Term Growth Estimate [6]
Cleco Corp	1,001	R	1,463	BBB	1.30	7.2%

1. Characteristics of the Sample

Q53. Table 1 lists the characteristics of the sample. Does the sample exactly match the risk characteristics of Dominion Virginia Power?

A53. No, the sample does not perfectly match the risk characteristics of the Dominion Virginia Power. In general, there is no perfect sample, and matching Dominion Virginia Power's business risk is particularly difficult at this time due to the process of re-regulation that is

set to begin in 2009. In addition, there is always a trade-off between sample size and imposing sample selection criteria designed to remove companies from the sample that may potentially bias the estimated costs of capital. In this case, I believe that this sample is the best currently available given the ongoing changes in the electric industry in general and in the Commonwealth of Virginia in particular.

2. Comparison of the Risk of the Sample to Risk of Dominion Virginia Power

Q54. Please summarize the general risk characteristics of the companies in the sample and those of Dominion Virginia Power.

A54. The sample consists of eight integrated utilities in traditionally regulated states, six companies with a PoLR obligation operating in states that have already transitioned to a deregulated electricity market and one company in a state (Arizona) that is partially deregulated. A summary of their risk characteristics is provided in Table 2 below.

Table 2a: Risk Characteristics of Sample Companies

	States Served	Electric Subsidiaries	PoLR [1]	Rate Cap for PoLR Utilities [2]	Fuel Cost Adjustment [3]	S&P Business Profile [4]	S&P Business Class [5]

Classification based on S&P's U.S. Utility and Power Ranking List where available.

[a] Entergy New Orleans is currently in Chapter 11 reorganization, but it represents less than 3% of the assets of Entergy Corp.

[b] States either repealed or delayed restructuring.

[c] Although Texas has a restructured market, Entergy operates in a traditionally regulated region of the state.

Q55. How does the risk of the sample compare to the risk of Dominion Virginia Power?

A55. At this time, the sample appears to be less risky than Dominion Virginia Power. Only six of the sample companies appear to have a PoLR obligation, and they are in states that have already moved to market costs for electric power. As a result, they face a different kind of regulatory uncertainty than Dominion Virginia Power currently does. Dominion Virginia Power faces the uncertainty of exactly how the Commission will interpret and implement the changes stemming from the passage of the re-regulation legislation. The goal of the legislation appears to be to reverse the process of electric restructuring in Virginia and to return the Commonwealth's electric utilities to fully integrated, traditionally regulated electric utilities. Although the legislation attempts to spell out the process by which re-regulation is to occur, there is substantial need for interpretation of the law by the Commission. There is uncertainty inherent in this need for interpretation, and investors generally dislike uncertainty. As a result Dominion Virginia Powers risk and its cost of capital will be higher until that uncertainty is resolved. Moreover, the legislation contains a number of provisions that potentially impose asymmetric risk on the Company. If the provisions of the law were implemented in a manner that realizes the concern regarding asymmetric risk, the Company would not expect to earn its cost of capital on average. As noted above, asymmetric risk may or may not affect the Company's cost of capital, but it definitely affects the Company's ability to earn the allowed rate of return.

Q56. How do the general risks of the integrated utilities in the sample compare to the risks faced by Dominion Virginia Power?

A56. The risks faced by the integrated utilities are generally less than those faced by Dominion Virginia Power at this time because the integrated electric companies do not face the uncertainty of the re-regulation process faced by Dominion Virginia Power. At some point in the future, Dominion Virginia Power's risk is expected to again be comparable to a traditionally regulated integrated electric utility, but that will occur only after the transition period is complete.

C. COST OF CAPITAL ESTIMATES

Q57. Please summarize the results of the risk positioning and DCF methodologies in estimating the average cost of capital for the benchmark sample, and the implications for Dominion Virginia Power's cost of equity?

A57. Table 3 summarizes the sample average ATWACCs derived from the risk positioning and DCF models, along with the implied cost of equity for Dominion Virginia Power at its filed regulatory capital structure with 50.7 percent equity.

Table 3: Cost of Equity Results

Regulatory Capital Structure: 50.7% Equity / 6.1% Preferred / 43.2% Debt *2008 Tax Rate: 38.8%*

	METHODS								
	RISK POSITIONING (Long-Term Risk-Free Rate)			RISK POSITIONING (Short-Term Risk-Free Rate)				DCF	
	CAPM	α = 0.5%	α = 1.5%	CAPM	α = 1%	α = 2%	α = 3%	Simple	Multi
[1] **Electric Sample***									
Cost of Equity	11.2%	11.3%	11.5%	11.5%	11.7%	11.8%	12.0%	11.4%	10.3%

[2] Risk Positioning Security Market Line Parameters:

Long-Term: Risk Free Rate Estimate: 5.1%; Estimated MRP: 6.5%

Short-Term: Risk Free Rate Estimate: 4.1%; Estimated MRP: 8.0%

Multi-Stage DCF Parameter: GDP Growth: 5.1%

Sources and Notes:

* Risk Positioning data is from Table No. MJV-12 and DCF data from Table No. MJV-8.

[1] The electric sample consists of Cleco Corp, Consolidated Edison, DTE Energy, Empire District Electric, Energy East Corp, Entergy Corp, FirstEnergy Corp, MGE Energy, NSTAR, Otter Tail Corp, Pinnacle West Capital Corp, PPL Corp, Puget Energy, SCANA Corp, and Southern Co.

[2] See Appendix C and D for details on the Risk Positioning and DCF parameters used in the estimates.

Q58. How did you determine a representative tax rate to use in your cost of capital estimation?

A58. The expected marginal income tax rate of 38.8 percent for Dominion Virginia Power was provided by the Company.

Q59. How are the cost of equity estimates derived from the risk positioning approach for the benchmark sample?

A59. I derive two sets of risk-positioning estimates, one using long-term forecasts of the risk-free rate and market risk premium, and one using short-term forecasts. The long-term interest rate forecast is 5.1 percent and the corresponding estimated market risk premium is 6.5 percent. When using the short-term risk-free rate of 4.1 percent, the estimated

MRP is 8.0 percent. Details on the derivation of these forecasts can be found in Appendix C.

For each estimated risk-free rate, the two risk positioning models (CAPM and ECAPM) are estimated utilizing the different values of the ECAPM parameter (0.5% and 1.5% for the long-term model and 1%, 2%, and 3% for the short-term model). I therefore obtain three long-term and four short-term estimates of each sample company's cost of equity. The results using the long-term risk-free rate are displayed in Table MJV-10, Panel A, and the results using the short-term risk-free rate are displayed in Table MJV-10, Panel B. Next, the cost of equity estimates are combined with each company's estimated cost of debt and preferred equity to calculate the company's ATWACC using each company's market value capital structure. These calculations and the resulting sample average ATWACCs are presented in Table No. MJV-11. Panels A-C rely on the cost of equity estimates from the long-term version of the model, while Panels D-G utilize the estimates from the short-term version of the model. The sample average ATWACCs and costs of equity at Dominion Virginia Power's 50.7 percent equity capital structure for each risk positioning cost of equity estimate are displayed in Table No. MJV-12. These results are summarized in Table 3 above.

Q60. What are the DCF estimates for the benchmark sample?

A60. For each sample company, cost-of-equity estimates are calculated for the two versions of the DCF method, the simple DCF model and multistage DCF model. The DCF estimates for each company are displayed in Table No. MJV-6, Panel A (simple DCF) and Panel B (multistage DCF). The sample average ATWACC for each method is calculated in Table No. MJV-7 and the resulting sample average ATWACC is used in Table No. MJV-8 to derive returns on equity at Dominion Virginia Power's 50.7 percent equity capital structure. These results are shown in Table 3 above, along with the sample average ATWACC numbers. Table 3 shows the estimated costs of equity to be 11.4 percent (simple DCF model) and 10.3 percent (multistage DCF model). The estimates from the simple DCF are comparable to the estimates from long-term risk positioning model but are slightly lower than the estimates from the short-term version of the risk positioning

model. The estimates from the multistage DCF model are about 100 bps lower the long-term risk positioning estimates (see Table 3: Cost of Equity Results above).

V. CONCLUSIONS

Q61. What are your conclusions from the DCF model regarding the cost of equity at Dominion Virginia Power's 50.7 percent equity ratio?

A61. The estimated costs of equity from the simple DCF model are 110 bps higher than the estimates from the multistage model, but are comparable to the risk positioning model estimates. The simple DCF model relies on company-specific growth rate forecasts, but those forecasts vary significantly among the companies in the sample, with Entergy and PPL displaying estimates greater than 10.5 percent while Consolidated Edison's and Pinnacle West's estimates are only 3.4 percent. The variation in growth rate forecasts strongly suggests that the simple DCF estimates are unreliable at this time because the long-run growth rate forecast drives the results, and there are no objective data on the long-run growth rate investors truly expect, nor on when the industry is expected to settle down into some sort of stable-growth equilibrium. The multistage DCF estimate is lower at 10.3 percent, but it is not reliable either for an industry in flux as is the electric utility industry at this time. Although I do not put much weight upon the DCF model results in my recommended cost of equity for Dominion Virginia Power, I believe that DCF cost capital estimates provide a useful check on the risk positioning results.

Q62. Do you have any comments regarding the results of the risk positioning models?

A62. The risk positioning results are summarized above in Table 3. At this time, the estimated costs of equity displayed in Table No. MJV-12 for the long-term version of the model are lower than for the short-term version of the model. Of those results, the CAPM values deserve the least weight, because this method does not adjust for the empirical finding that the cost of capital is less sensitive to beta than predicted by the CAPM (which my testimony considers by using the ECAPM). Conversely, the ECAPM numbers deserve the most weight, because this method adjusts for the empirical findings. The cost of equity estimates using the long-term risk free rate and adjusted for a capital structure with

a 50.7 percent equity ratio range from 11.2 to 11.5 percent, while for the short-term risk-free rate estimates range from 11.5 to 12.0 percent.

The estimates based upon the short-term risk-free rate are about 50 basis points higher on average than the estimates using the long-term risk-free rate. This reflects the flatter slope of the yield curve at this time. Panel A of Table No. MJV-9 shows that 30-day Treasury bills are currently yielding an average of 4.86 percent compared to 5.14 percent for long-term Treasury bonds. This relationship between the yield on short-term and long-term Treasury securities is unusual. Yields on long-term Treasury bonds have averaged about 150 basis points more than the yields on 30-day Treasury bills over the last 80 years. (See Workpaper #1, Panel B to Table No. MJV-9) The yield on short-term Treasury bills reflects the efforts by the Federal Reserve ("Fed") to prevent the rate of inflation from increasing any further. If the Fed believes that inflation is not yet contained, short-term rates and perhaps long-term rates as well are likely to increase further. Long-term rates have been increasing somewhat in recent months, and much of the relatively recent decline in market prices can be attributed to fears of increases in interest rates. On the other hand, if inflation is judged to be under control, short-term rates may decline as fears of recession replace those of inflation. In its most recent Open Market Committee meeting, the Fed decided to keep the Federal Funds rate constant at 5¼ percent but expressed concern that the risk of "inflation will fail to moderate as expected."[19] The implication is that interest rates will increase if inflation does not moderate.

Q63. Given the results of the two models and the comparison of the risk of Dominion Virginia Power to the sample, what is your conclusion regarding the cost of equity for the Company?

A63. Focusing on the middle values in Table 3 for the results from the long-term risk positioning model (ECAPM with $\alpha = 0.5$), the average ATWACC for the sample is 7.8 percent, with a corresponding cost of equity estimate of 11.3 percent. The results for the short-term version of the risk positioning model (ECAPM with $\alpha = 2.0$) is 8.1 percent ATWACC with a corresponding cost of equity estimate of 11.8 percent. As noted above,

the current uncertainty regarding the transition from a partially deregulated company to a fully integrated, traditionally regulated utility imposes additional risk on the Company at this time which means that the Company is somewhat more risky on average than the sample. In addition, there are fears that long-term interest rates may increase in the near future which means that current cost of equity estimates would be underestimated.

Considering all of the evidence from both models and the risk of the Company, the best point estimate for the cost of equity for Dominion Virginia Power is 11¾ percent. However, it is more correct to say that the estimates from the sample adjusted for differences in risk provide a range of values from a low of 11¼ percent to a high of 12¼ percent. This result is slightly above the upper end of the range of estimates from the risk positioning model using the long-term risk free rate and reflects the higher risk level of the Company currently compared to the sample. The short-term version of the model captures some of the effect of an increase in long-term interest rates in future because short-term interest rates are already high relative to long-term rates. The 11¾ percent estimate is about the middle of the estimates from the short-term version of the model. Although I rely primarily on the long-tem version of the model, the slight increase in the estimate for the Company over the range from the long-term model is supported by both the differences in risk and by consideration of increasing interest rates. As previously noted, in estimating the cost of equity I round to the nearest ¼ percent (25 basis points) and estimate a range of plus and minus ½ percent around the point estimate because I do not believe that cost of capital estimates can be made more precisely than that.

Q64. Does this conclude your testimony?

A64. Yes.

[19] See Federal Reserve Release, *Press Release*, June 28, 2007.

APPENDIX A

RESUMÉ

MICHAEL J. VILBERT **PRINCIPAL**

Michael Vilbert is an expert in cost of capital, financial planning and valuation who has advised clients on these matters in the context of a wide variety of investment and regulatory decisions. He received his Ph.D. in Financial Economics from the Wharton School of the University of Pennsylvania, an MBA from the University of Utah, an M.S. from the Fletcher School of Law and Diplomacy, Tufts University, and a B.S. degree from the United States Air Force Academy. He joined The Brattle Group in 1994 after a career as an Air Force officer, where he served as a fighter pilot, intelligence officer, and professor of finance at the Air Force Academy.

REPRESENTATIVE CONSULTING EXPERIENCE

- In a securities fraud case, Dr. Vilbert designed and created a model to value the private placement stock of a drug store chain as if there had been full disclosure of the actual financial condition of the firm. He analyzed key financial data and security analyst's reports regarding the future of the industry in order to recreate pro forma balance sheet and income statements under a variety of scenarios designed to establish the value of the firm.

- For pharmaceutical companies rebutting price-fixing claims in antitrust litigation, Dr. Vilbert was a member of a team which prepared a comprehensive analysis of industry profitability. The analysis replicated, tested and critiqued the major recent analyses of drug costs, risks and returns. The analyses helped develop expert witness testimony to rebut allegations of excess profits.

- For an independent electric power producer, Dr. Vilbert created a model that analyzed the reasonableness of rates and costs filed by a natural gas pipeline. The model not only duplicated the pipeline's rates, but it also allowed simulation of a variety of "what if" scenarios associated with cost recovery under alternative time patterns and joint cost allocations. Results of the analysis were adopted by the intervenor group for negotiation with the pipeline.

- For the CFO of an electric utility, Dr. Vilbert developed the valuation model used to support a stranded cost estimation filing. The case involved a conflict between two utilities over the responsibility for out-of-market costs associated with a power purchase contract between them. In addition, he advised and analyzed cost recovery mechanisms

that would allow full recovery of the stranded costs while providing a rate reduction for the company's rate payers.

- Dr. Vilbert has testified as well as assisted in the preparation of testimony and the development of estimation models in numerous cost of capital cases for natural gas pipeline, water utility and electric utility clients before the Federal Energy Regulatory Commission ("FERC") and state regulatory commissions. These have spanned standard estimation techniques (e.g., Discounted Cash Flow and Risk Positioning models). He has also developed and applied more advanced models specific to the industries or lines of business in question, e.g., based on the structure and risk characteristics of cash flows, or based on multi-factor models that better characterize regulated industries.

- Dr. Vilbert has valued several large, residual oil-fired generating stations to evaluate the possible conversion to natural gas or other fuels. In these analyses, the expected pre- and post-conversion station values were computed using a range of market electricity and fuel cost conditions.

- For a major western electric utility, Dr. Vilbert helped prepare testimony that analyzed the prudence of QF contract enforcement. The testimony demonstrated that the utility had not been compensated in its allowed cost of capital for major disallowances stemming from QF contract management.

- Dr. Vilbert analyzed the economic need for a major natural gas pipeline expansion to the Midwest. This involved evaluating forecasts of natural gas use in various regions of the United States and the effect of additional supplies on the pattern of natural gas pipeline use. The analysis was used to justify the expansion before the FERC and the National Energy Board of Canada.

- For a Public Utility Commission in the Northeast, Dr. Vilbert analyzed the auction of an electric utilities purchase power agreements to determine whether the outcome of the auction was in the ratepayers' interest. The work involved the analysis of the auction procedures as well as the benefits to ratepayers of transferring risk of the PPA payments to the buyer.

- Dr. Vilbert led a team tasked to determine whether bridge tolls were "just and reasonable" for a non-profit port authority. Determination of the cost of service for the authority required estimation of the value of the authority's assets using the trended original cost methodology as well as evaluation of the operations and maintenance budgets. Investment costs, bridge traffic information and inflation indices covering a 75 year period were utilized to estimate the value of four bridges and a passenger transit line valued in excess of $1 billion.

- Dr. Vilbert helped a recently privatized railroad in Brazil develop an estimate of its revenue requirements, including a determination of the railroad's cost of capital. He also helped evaluate alternative rate structures designed to provide economic incentives to shippers as well as to the railroad for improved service. This involved the explanation

and analysis of the contribution margin of numerous shipper products, improved cost analysis and evaluation of bottlenecks in the system.

- For a utility in the Southeast, Dr. Vilbert quantified the company's stranded costs under several legislative electric restructuring scenarios. This involved the evaluation of all of the company's fossil and nuclear generating units, its contracts with Qualifying Facilities and the prudence of those QF contracts. He provided analysis concerning the impact of securitizing the company's stranded costs as a means of reducing the cost to the rate payers and several alternative designs for recovering stranded costs.

- For a recently privatized electric utility in Australia, Dr. Vilbert evaluated the proposed regulatory scheme of the Australian Competition and Consumer Commission for the company's electric transmission system. The evaluation highlighted the elements of the proposed regulation which would impose uncompensated asymmetric risks on the company and the need to either eliminate the asymmetry in risk or provide additional compensation so that the company could expect to earn its cost of capital.

- For an electric utility in the Southwest, Dr. Vilbert helped design and create a model to estimate the stranded costs of the company's portfolio of Qualifying Facilities and Power Purchase contracts. This exercise was complicated by the many variations in the provisions of the contracts that required modeling in order to capture the effect of changes in either the performance of the plants or in the estimated market price of electricity.

- Dr. Vilbert helped prepare the testimony responding to a FERC request for further comments on the appropriate return on equity for electric transmission facilities. In addition, Dr. Vilbert was a member of the team that made a presentation to the FERC staff on the expected risks of the unbundled electric transmission line of business.

- Dr. Vilbert and Mr. Frank C. Graves, also of The Brattle Group, prepared testimony evaluating an innovative Canadian stranded cost recovery procedure involving the auctioning of the output of the province's electric generation plants instead of the plants themselves. The evaluation required the analysis of the terms and conditions of the long-term contracts specifying the revenue requirements of the plants for their entire forecasted remaining economic life and required an estimate of the cost of capital for the plant owners under this new stranded cost recovery concept.

- Dr. Vilbert served as the neutral arbitrator for the valuation of a petroleum products tanker. The valuation required analysis of the Jones Act tanker market and the supply and demand balance of the available U.S. constructed tanker fleet.

TESTIMONY

Direct and rebuttal testimony before the Alberta Energy and Utilities Board on behalf of TransAlta Utilities Corporation in the matter of an application for approval of its 1999 and 2000 generation tariff, transmission tariff, and distribution revenue requirement, October 1998.

Direct testimony before the Federal Energy Regulatory Commission on behalf of Central Maine Power in Docket No. ER00-982-000, December 1999.

Direct testimony before the Alberta Energy and Utilities Board on behalf of TransAlta Utilities Corporation for approval of its 2001 transmission tariff, May 2000.

Direct testimony before the Federal Energy Regulatory Commission on behalf of Mississippi River Transmission Corporation in Docket No. RP01-292-000, March 2001.

Written evidence, rebuttal, reply and further reply before the National Energy Board in the matter of an application by TransCanada PipeLines Limited for orders pursuant to Part I and Part IV of the *National Energy Board Act*, Order AO-1-RH-4-2001, May 2001, Nov. 2001, Feb. 2002.

Written evidence before the Public Utility Board on behalf of Newfoundland & Labrador Hydro - Rate Hearings, October 2001.

Direct testimony (with Bill Lindsay) before the Federal Energy Regulatory Commission on behalf of DTE East China, LLC in Docket No. ER02-1599-000, April 2002.

Direct and rebuttal reports before the Arbitration Panel in the arbitration of stranded costs for the City of Casselberry, FL, Case No. 00-CA-1107-16-L, July 2002.

Direct reports before the Arbitration Board for Petroleum products trade in the Arbitration of the Military Sealift Command vs. Household Commercial Financial Services, fair value of sale of the Darnell, October 2002.

Direct testimony and hearing before the Arbitration Panel in the arbitration of stranded costs for the City of Winter Park, FL, In the Circuit Court of the Ninth Judicial Circuit in and for Orange County, FL, Case No. C1-01-4558-39, December 2002.

Direct testimony before the Federal Energy Regulatory Commission on behalf of Florida Power Corporation, dba Progress Energy Florida, Inc. in Docket No. SC03-___-000, March 2003.

Direct report before the Arbitration Panel in the arbitration of stranded costs for the Town of Belleair, FL, Case No. 000-6487-C1-007, April 2003.

Direct and rebuttal reports before the Alberta Energy and Utilities Board in the matter of the Alberta Energy and Utilities Board Act, R.S.A. 2000, c. A-17, and the Regulations under it; in the matter of the Gas Utilities Act, R.S.A. 2000, c. G-5, and the Regulations under it; in the matter of the Public utilities Board Act, R.S.A. 2000, c. P-45, as amended, and the Regulations

under it; and in the matter of Alberta Energy and Utilities Generic Cost of Capital Hearing, Proceeding No. 1271597, July 2003, November 2003.

Written evidence before the National Energy Board in the matter of the National Energy Board Act, R.S.C. 1985, c. N–7, as amended, (Act) and the Regulations made under it; and in the matter of an application by TransCanada PipeLines Limited for orders pursuant to Part IV of the *National Energy Board Act*, for approval of Mainline Tolls for 2004, RH-2-2004, January 2004.

Direct and rebuttal testimony before the Public Service Commission of West Virginia, on Cost of Capital for West Virginia-American Water Company, Case No 04-0373-W-42T, May 2004.

Direct and rebuttal testimony before the Federal Energy Regulatory Commission, on Energy Allocation of Debt Cost for Incremental Shipping Rates for Edison Mission Energy, Docket No. RP04-274-000, December 2004 and March 2005.

Direct testimony before the Arizona Corporation Commission, Cost of Capital for Paradise Valley Water Company, a subsidiary of Arizona-American Water Company, Docket No. WS-01303A-05, May 2005.

Written evidence before the Ontario Energy Board, Cost of Capital for Union Gas Limited, Inc., Docket No. EB-2005-0520, January 2006.

Direct and rebuttal testimony before the Pennsylvania Public Utility Commission, Return on Equity for Metropolitan Edison Company, Docket No. R-00061366 and Pennsylvania Electric Company, Docket No. R-00061367, April 2006 and August 2006.

Expert report in the United States Tax Court, Docket No. 21309-05, 34th Street Partners, DH Petersburg Investment, LLC and Mid-Atlantic Finance, Partners Other than the Tax Matters Partner, Petitioner, v. Commissioner of Internal Revenue, Respondent, July 28, 2006.

Direct and supplemental testimony before the Federal Energy Regulatory Commission, Docket No. ER06-427-003, on behalf of Mystic Development, LLC on the Cost of Capital for Mystic 8 and 9 Generating Plants Operating Under an Reliability Must Run Contract, August 2006 and September 2006.

Direct testimony before the Federal Energy Regulatory Commission, Docket No. ER07-46-000, on behalf of Northwestern Corporation on the Cost of Capital for Transmission Assets, October 2006.

Direct and rebuttal testimony before the Tennessee Regulatory Authority, Case No. 06-00290, on behalf of Tennessee American Water Company, on the Cost of Capital, November, 2006 and April 2007.

Direct testimony before the Public Service Commission of Wisconsin, Docket No. _____, on behalf of Wisconsin Energy Corporation, on the Cost of Capital for Wisconsin Electric Power Company and Wisconsin Gas LLC, May 2007.

Rebuttal testimony before the California Public Utilities Commission, Docket No. A. 07-01-036-39, on behalf of California-American Water Company, on the Cost of Capital, May 2007.

Direct testimony before the Public Utilities Commission of the State of South Dakota, Docket No. NG-07-____, on behalf of NorthWestern Corporation, on the Cost of Capital for NorthWestern Energy Company's natural gas operations in South Dakota, June 2007.

Direct testimony before the Public Utilities Commission of Ohio, Case No. 07-551-EL-AIR, Case No. 07-552-EL-ATA, Case No. 07-553-EL-AAM, and Case No. 07-554-EL-UNC, on behalf of Ohio Edison Company, The Toledo Edison Company, and The Cleveland Electric Illuminating Company, on the cost of capital for the FirstEnergy Company's Ohio electric distribution utilities, June 2007.

APPENDIX B

SELECTING THE GAS LDC SAMPLE AND USE OF MARKET VALUES

I. SAMPLE SELECTION AND THE SAMPLE'S CHARACTERISTICS 2

II. MARKET VALUE CAPITAL STRUCTURE, COSTS OF DEBT & COSTS OF PREFERRED EQUITY 6

I. SAMPLE SELECTION AND THE SAMPLE'S CHARACTERISTICS

Q1. How did you select your sample of electric utilities?

A1. The goal was to create a sample of companies whose primary business is as a regulated electric utility with business risk generally similar to that of Dominion Virginia Electric Power Company ("Dominion Virginia Power"). To construct this sample, I started with the universe of 68 electric companies under the East, Central and West categories listed in the *Value Line Plus Edition*. From this group, companies were first eliminated if their operating regions were outside of the continental USA or if they were primarily or solely engaged in generation and/or transmission. I then applied my standard selection criteria outlined in my direct testimony to remove companies that have characteristics that may bias the cost of capital estimates.

Specifically, I eliminated all companies whose S&P bond rating as reported by Bloomberg was not investment grade, i.e., less than BBB-. To guard against measurement bias caused by "thin trading," I also restricted the sample to companies with total operating revenues greater than $300 million (USD) in 2006 as reported by Bloomberg.[1] Companies were also required to have no significant mergers and acquisition activity over the past five years, again to guard against measurement bias. The screen for merger activity was primarily done by scanning each company's news history on Bloomberg and a search of company web pages. To further ensure comparability to Dominion Virginia Power's regulated electric operations, companies whose share of regulated assets were not estimated to be at least "Mostly Regulated", as classified by the Edison Electric Institute ("EEI"), were removed.[2]

Finally, I required that the companies have historical data available from Bloomberg and that they had no dividend cuts or restatement of financial statements in the past five years, since the latter can be signs of financial distress.

---

[1] Data was reviewed during the second week of June 2007.

[2] EEI has three classifications for electric utilities based upon the percentage of total assets that are regulated. The categories are Regulated (> 80% regulated), Mostly Regulated (50% to 80% regulated) and Diversified (< 50% regulated). See *EEI Stock Performance, Q1 2007 Financial Update,* pg. 4.

A total of 15 companies met all of these requirements: Cleco Corp, Consolidated Edison, DTE Energy Co, Empire District Electric, Energy East Corp, Entergy Corp, FirstEnergy Corp, MGE Energy, NSTAR, Otter Tail Corp, Pinnacle West Capital Corp, PPL Corp, Puget Energy Inc., SCANA Corp, and Southern Corp.

Q2. Please elaborate on how companies were eliminated from your sample?

A2. Eight companies were excluded due to less than investment grade credit rating – namely Avista Corp, Central Vermont Public Service Corp, CH Energy Group Inc, Mirant Corp, PG&E Corp, Reliant Energy Inc, Sierra Pacific Resources, and UIL Holdings Corp. Four more companies – AMEN Properties, Green Mountain Power Corp, ITC Holdings Corp, and Maine & Maritimes Corp - were excluded for less than $300 million in 2006 revenues. Of the remaining 56 companies, 18 had excessive merger and acquisition activity ("M&A") and 16 had dividend cuts over the past five years. Hawaiian Electric Industries Inc was excluded for being outside of the continental U.S., Pepco Holdings Inc because it did not issue dividends until late 2002, and Vectren Corp because it receives a substantial portion of its income from regulated gas activities. Finally, Dominion Resources Inc, MDU Resources Group, OGE Energy Corp and Sempra were excluded because EEI classifies them as having less than fifty percent of regulated assets.

Q3. Are there any issues with the remaining companies in your sample?

A3. Possibly. Although not enough merger and acquisition activity to eliminate them from the sample, three of nine companies had more activity over the past five years than the others: Cleco, Empire District Electric and Entergy. Cleco Corp.'s beta is also substantially higher at 1.30 than any of the other sample companies'. Two sample companies, Empire District and MGE Energy, are smaller companies compared to the others in the sample, but both have a book value of assets of about a $1 billion making them "large" by most standards. DTE Energy, FirstEnergy Corp, Otter Tail Corp, PPL Corp, and SCANA Corp only fall into EEI's "Mostly Regulated" category, indicating that between 50 and 80 percent of their assets are subject to regulation. (See Table No. MJV-2 for a list of the regulated asset categorizations by EEI for each sample company.) A potential problem for the DCF estimates is that sample companies growth rate forecasts vary substantially company-to-company. For example, Entergy and PPL each have a

combined growth rate estimate of over 10.5 percent, while Consolidated Edison's and Pinnacle West's combined estimate are both 3.4 percent (see column [6], Table No. MJV-5).[3] As such, the growth rates estimates do not support the view that investors are expecting growth rates equal to the single perpetual growth rate assumed in the simple DCF model. Again, this may be an indication that the industry conditions are not fully met for the reliable application of the DCF model. Recall that the DCF model requires stable industry conditions so that dividends, earnings, stock prices etc. are all growing at a constant rate.

Q4. How does the risk of the sample compare to the risk of Dominion Virginia Power?

A4. In general, the sample appears to be less risky than Dominion Virginia Power at this time. The sample consists of eight integrated utilities in traditionally regulated states, six companies with a provider of last resort ("PoLR") obligation operating in states that have already transitioned to a deregulated electricity market and one company in a state (Arizona) that is partially deregulated. A summary of their risk characteristics is provided in Table 2 in my Direct Testimony. All but Empire Electric and PPL Corp have some form of fuel-cost adjustment mechanisms covering the bulk of their operations. Of the six PoLR companies, two are in states that still have capped rates, but four are in states that have moved to market based rates. As a result, they face a different kind of regulatory uncertainty than does Dominion Virginia Power. All sample companies face the uncertainty associated with the recent volatility of fuel prices. Consumers have demonstrated an aversion to highly volatile energy prices, so regulatory authorities may be reluctant to allow full recovery of energy prices that are too variable.

Depending upon the recovery mechanism for the costs of providing POLR service, the risks faced by electric distribution companies with a POLR obligation may be greater than or less than those of an integrated utility. The biggest risk difference between the two is that integrated utilities own or contract for the generation capacity to meet the power needs of their customers. Although they are still exposed to changes in fuel prices

[3] Moreover, Bloomberg does not provide a BEst Estimate for MGE Energy, which means there is only one growth estimate for this company, and it only provides one growth estimate for Cleco Corp and Empire District Electric.

as well as the construction and operating risk of owning generation, they have a natural hedge against volatile energy prices through their ownership of generation assets. POLR companies, on the other hand, are potentially exposed to changes in market prices not related to the volatility of fuel prices, because they must purchase power at market prices.

Dominion Virginia Power's current situation is unique in that it is in a transition from being a partially deregulated utility with a PoLR responsibility to becoming a traditionally-regulated integrated electric utility. The Company owns generation to meet its PoLR responsibilities, but it is also currently a net importer of power so it faces market risk on the cost of power that is imported. In addition, the Company is operating under a rate cap which may prevent the full cost of providing service from being passed through to customers. As noted above, only two of the sample companies with a PoLR responsibility are operating in states with a rate cap. The other sample companies are traditionally regulated utilities, but they are not undergoing restructuring at this time. For these reasons, Dominion Virginia Power is more risky than the sample.

Q5. How does the restructuring legislation affect the risk of Dominion Virginia Power?

A5. Ultimately, I believe that the legislation will result in a modest decrease in risk for the Company, but during the transition period there will be substantial uncertainty. The legislation must be implemented by the Commission, and implementation will require interpretation of a number of the provisions of the legislation. As a result, there will be a transition period during which the Commission will work through and interpret the steps envisioned in the legislation. The outcomes of the judgments necessary to implement the legislation are unknown at this time and may be different than currently anticipated by investors, customers, legislators or the Company. Investors dislike uncertainty and generally require a higher return in compensation. Until that uncertainty is resolved, the Company will be perceived as more risky by investors than it will be when the transition period is complete.

II. MARKET VALUE CAPITAL STRUCTURE, COSTS OF DEBT & COSTS OF PREFERRED EQUITY

Q6. What capital structure information do you require?

A6. For reasons discussed in my written evidence and explained in detail in Appendix E, explicit evaluation of the market-value capital structures of the sample companies versus the capital structure used for rate making is vital for a correct interpretation of the market evidence. This requires estimates of the market values of common and preferred equity and debt, and the current market costs of preferred equity and debt.

Q7. How do you calculate the market-value capital structures of the sample companies?

A7. I estimate the capital structure for each company by estimating the market values of common equity, preferred equity and debt from publicly available data. The calculations are in Panels A to O of Table No. MJV-3.

The market value of equity is straightforward: the price per share times the number of shares outstanding. The market value of preferred is set equal to its book value because the portion of the capital structure financed with preferred equity is generally small. The market value of debt is estimated at the book value of debt reported by Bloomberg plus or minus the difference in the estimated fair (market) value and book value of long-term debt as reported in the companies' 10-K's or annual reports.[4]

For purposes of assessing financial risk to common shareholders, I add an adjustment for short-term debt to the debt portion of the capital structure. This adjustment is used only for those companies whose short-term (current) liabilities exceed their short-term (current) assets. I add an amount equal to the minimum of the difference between short-term liabilities and short-term assets or the amount of short-term debt. The reason for this adjustment is to recognize that when current liabilities exceed current assets, a portion of the companies long-term assets are being financed, in effect, by short-term debt.

[4] See Panels A through O in Tables No. MJV-3 for details. The adjustment relies on the difference between the companies' self-reported fair value of long-term debt and the carrying value of the same line items. This information was obtained from the sample companies' annual reports.

The market value capital structure is calculated to be consistent with the time period over which the cost of capital is estimated for the sample. The capital structure is determined over the historical period over which the relevant risk positioning parameters were determined and as of the date analysts provide forward looking growth forecasts. Therefore, Table No. MJV-3 reports the market value capital structure at year end for the years ending 2002 – 2006, and the first quarter of 2007. The output of this table is the market equity-to-value, debt-to-value, and preferred equity-to-value ratios. The overall cost of capital calculation for the risk positioning estimates rely on the average of the market value capital structure computed for the years 2002 through first quarter of 2007, as shown in Table No. MJV-4. The results in columns [1]-[3] are used in the DCF model calculations, while columns [4]-[6] are for the risk positioning models.

Q8. How do you estimate the current market cost of preferred equity?

A8. For companies with preferred equity, the cost of preferred equity for each company was set equal to the yield on an index of preferred stock as reported in the Mergent Bond Record corresponding to the S&P rating of that company's debt. The yields from *Mergent Bond Record* were as of May 2007. In general, the average amount of preferred equity in the sample companies' capital structures is very small and frequently zero. No company in either sample has more than two percent on average.[5]

Q9. How do you estimate the current market cost of debt?

A9. The market cost of debt for each company in the DCF analysis is the current yield reported by Bloomberg for a public utility company bond corresponding to the sample company's current debt rating as classified by S&P. The risk positioning analysis, on the other hand, uses the current yield of a utility bond that corresponds to the five-year average debt rating of each company so as to match consistently the horizon of information used by *Value Line* to estimate company betas. The current S&P debt ratings were obtained from Bloomberg.

[5] Dominion Virginia Power, on the other hand, has about six percent preferred equity in its regulatory capital structure.

The fifteen day average yield on A-rated Public Utility bonds was 6.23 percent as of June 11, 2007, and 6.43 percent on average for BBB-rated Public Utility bonds. (See Panel A of Workpaper #1 to Table No. MJV-11 for the yields on utility bonds and preferred stock by credit rating.) Calculation of the after-tax cost of debt uses the marginal tax rate 38.8 percent provided by the company.

APPENDIX C

RISK POSITIONING METHODOLOGY AND EMPIRICAL RESULTS

I. EQUITY RISK PREMIUM METHODOLOGY C-2

A. THE BASIC EQUITY RISK PREMIUM MODEL C-2
B. MARKET RISK PREMIUM C-3
C. RELATIVE RISK C-10
D. INTEREST RATE FORECAST C-13
E. COST OF CAPITAL MODELS C-13

II. EMPIRICAL EQUITY RISK PREMIUM RESULTS C-16

A. RISK-FREE INTEREST RATE FORECAST C-16
B. BETAS AND THE MARKET RISK PREMIUM C-17
1. Beta Estimation Procedures C-17
2. Market Risk Premium Estimation C-17
C. COST OF CAPITAL ESTIMATES C-17

Q1. What is the purpose of this appendix?

A1. This appendix reviews the principles behind the risk positioning methodologies, describes the estimation of the parameters used in the models, and details the cost of capital estimates obtained from these methodologies. This appendix intentionally repeats portions of my direct testimony, because I want the reader to be able to have a full discussion of the issues addressed here, rather than having to continually turn back to the corresponding section of the testimony.

I. EQUITY RISK PREMIUM METHODOLOGY

Q2. How is this section of the appendix organized?

A2. It first reviews the basic nature of the equity risk premium approach. It then discusses the individual components of the model: the benchmark risk premium, the relative risk of the company or line of business in question, the appropriate interest rate, and the combination of these elements in a particular equity risk premium model.

A. THE BASIC EQUITY RISK PREMIUM MODEL

Q3. How does the equity risk premium model work?

A3. The equity risk premium approach estimates the cost of equity as the sum of a current interest rate and a risk premium. (It therefore is sometimes also known as the "risk premium" or the "risk positioning" approach.)

This approach may sometimes be applied informally. For example, an analyst or a commission may check the spread between interest rates and what is believed to be a reasonable estimate of the cost of capital at one time, and then apply that spread to changed interest rates to get a new estimate of the cost of capital at another time.

More formal applications of equity risk premium method implement the second approach to cost of capital estimation. They use information on all securities to identify the security market line (Figure 1 in the body of the testimony) and derive the cost of capital for the individual security based on that security's relative risk. This equity risk premium

approach is widely used and underlies most of the current scholarly research on the nature, determinants and magnitude of the cost of capital.

Q4. How are "more formal applications" put into practice?

A4. The essential benchmarks that determine the security market line are the risk-free interest rate and the premium that a security of average risk commands over the risk-free rate. This premium is commonly referred to as the "market risk premium" ("MRP"), i.e., the excess of the expected return on the average common stock over the risk-free interest rate. In the equity risk premium approach the risk-free interest rate and MRP are common to all securities. A security-specific measure of relative risk (beta) is estimated separately and combined with the MRP to obtain the company-specific risk premium.

In principle, there may be more than one factor affecting the expected stock return, each with its own security-specific measure of relative risk and its own benchmark risk premium. For example, the "arbitrage pricing theory" and other "multi-factor" models have been proposed in the academic literature. These models estimate the cost of capital as the sum of a risk-free rate and several security-specific risk premia. However, none of these alternative models has emerged in practice as "the" improvement to use instead of the original, single-factor model. I use the traditional single-factor model in this testimony.

Accordingly, the required elements in my formal equity risk premium approach are the market risk premium, an objective measure of relative risk, the risk-free rate that corresponds to the measure of the market risk premium, and a specific method to combine these elements into an estimate of the cost of capital.

B. MARKET RISK PREMIUM

Q5. Why is a risk premium necessary?

A5. Experience (e.g., the U.S. market's October Crash of 1987) demonstrates that shareholders, even well diversified shareholders, are exposed to enormous risks. By investing in stocks instead of risk-free Government bills, investors subject themselves not

only to the risk of earning a return well below those they expected in any year but also to the risk that they might lose much of their initial capital. This is why investors demand a risk premium.

I estimate two versions of the Capital Asset Pricing Model ("CAPM"). The first version measures the market risk premium as the risk premium of average risk common stocks over the long-term risk-free rate. The second version measures the risk premium relative to a short-term risk-free rate, which is the usual measure of the "market risk premium" used in capital market theories.

Q6. Please discuss some of the issues involved in selecting the appropriate MRP?

A6. To determine the cost of capital in a regulatory proceeding, the MRP should be used with a forecast of the same interest rate used to calculate the MRP (i.e., the short-term Treasury bill rate or the long-term Government rate). For example, it would be inconsistent to utilize a short-term risk-free with an estimate of the MRP derived from comparisons to long-term interest rates. In addition, the appropriate measure of the MRP should be based upon the arithmetic mean not the geometric mean return.[1] The arithmetic mean is the simple average while the geometric mean is the compound rate of return between two periods.

Q7. How do you estimate the MRP?

A7. There is presently little consensus on "best practice" for estimating the MRP, which does not mean that each approach is equally valid. For example, the latest edition of the leading graduate textbook in corporate finance, after recommending use of the arithmetic average realized excess return on the market for many years (which for a while was noticeably over 9 percent), now reviews the current state of the research and expresses the view that the a range between 5 to 8 percent is reasonable for the U.S.[2,3]

---

[1] See, for example, Morningstar, Stocks, Bonds, Bills, and Inflation: Valuation Edition 2007 Yearbook, pp. 75-77.

[2] Richard A. Brealey, Stewart C. Myers, and Franklin Allen, *Principles of Corporate Finance*, McGraw-Hill, 8th edition, 2006, pp. 151-154.

My written testimony considers both the historical evidence and the results of scholarly studies of the factors that affect the risk premium for average-risk stocks in order to estimate the benchmark risk premium investors currently expect. I consider the historical difference in returns between the Standard and Poor's 500 Index ("S&P 500") and the risk-free rate, recent academic literature on the MRP and the results of recent surveys to estimate the market risk premium.

Q8. Please summarize the recent literature on the MRP and the conclusions you draw from it?

A8. Some recent research based upon U.S. data challenges the conventional wisdom of using the arithmetic average historical excess returns to estimate the MRP. However, after reviewing the issues in the debate, I remain skeptical for several reasons that the market risk premium has declined in the U.S. as much as is claimed in some of the literature.

First, despite eye-catching claims like "equity risk premium as low as three percent,"[4] and "the death of the risk premium,"[5] not all recent research arrives at the same conclusion. In his presidential address to the American Finance Association in 2001, Professor Constantinides seeks to estimate the unconditional equity premium based on average historical stock returns.[6] (Note that this address was based upon evidence just before the major fall in market value.) He adjusts the average returns downward by the change in price-earnings ratio because he assumes no change in valuations in an unconditional state. His estimates for 1926 to 2000 and 1951 to 2000 are 8.0 percent and 6.0 percent, respectively, over the 3-month T-bill rate. In another published study in 2001, Professors Harris and Marston use the DCF method to estimate the market risk

---

[3] In past editions, the authors expressed the view that they are "most comfortable" with values toward the upper end of that range, but this language does not appear in the 8th edition. Although Professor Myers still holds this view, this language and other sections were dropped to accommodate a request to reduce the length of the text.

premium for the U.S. stocks.[7] Using analysts' forecasts to proxy for investors' expectation, they conclude that over the period 1982-1998 the MRP over the *long-term* risk-free rate is 7.14 percent. As yet another example, the paper by Drs. Ibbotson and Chen (2003) adopts a supply side approach to estimate the forward looking long-term sustainable equity returns and equity risk premium based upon economic fundamentals. Their equity risk premium over the *long-term* risk-free rate is estimated to be 3.97 percent in geometric terms and 5.90 percent on an arithmetic basis. They conclude their paper by stating that their estimate of the equity risk premium is "far closer to the historical premium than being zero or negative."[8]

Second, Professor Ivo Welch surveyed a large group of financial economists in 1998 and 1999. The average of the estimated MRP was 7.1 percent in Prof. Welch's first survey and 6.7 percent in his second survey which was based on a smaller number of individuals. However, a more recent survey[9] by Prof. Welch reported only a 5.5 percent MRP.[10] In characterizing these results Prof. Welch notes that "[T]he equity premium consensus forecast of finance and economics professors seems to have dropped during the last 2 to 3 years, a period with low realized equity premia."[11]

The above quotation from Prof. Welch emphasizes the caution that must attend survey data even from knowledgeable survey participants: the outcome is likely to change quickly with changing market circumstances. Regulatory commissions should not, in my opinion, attempt to keep pace with such rapidly changing opinions.

Third, some of the evidence for negative or close to zero market risk premium simply does not make sense. Despite the relatively high valuation levels, stock returns remain

[11] *Ibid*, p. 8.

much more volatile than Treasury bond returns. I am not aware of any empirical or theoretical evidence showing that investors would rationally hold equities and not expect to earn a positive risk premium for bearing their higher risk.

Fourth, I am unaware of a convincing theory for why the future MRP should have substantially declined. At the height of the stock market bubble in the U.S., many claimed that the only way to justify the high stock prices would be if the MRP had declined dramatically,[12] but this argument was heard less frequently after the market declined substantially from its tech bubble high. All else equal, a high valuation ratio such as price-earnings ratio implies a low required rate of return, hence a low MRP. However, there is considerable debate about whether the high level of stock prices (despite the burst of the internet bubble from its high in the summer of 2000) represents the transition to a new economy or is simply an "irrational exuberance," which cannot be sustained for the long term. If the former case is true, then the MRP may have decreased permanently. Conversely, the long-run MRP may remain the same even if expected market returns in the short-term are smaller.

Another common argument for a lower expected MRP is that the U.S. experienced very remarkable growth in the 20th century that was not anticipated at the start of the century. As a result, the average realized excess return is overestimated meaning the standard method of estimating the MRP would be biased upward. However, one recent study by Profs. Jorion and Goetzmann finds, under some simplifying assumptions, that the so-called "survivorship bias" is only 29 basis points.[13] Furthermore, "[I]f investors have overestimated the equity premium over the second half of the last century, Constantinides

[12] See Robert D. Arnott and Peter L. Bernstein, "What Risk Premium is 'Normal'?," *Financial Analysts Journal* 58:64-85, for an example.

[13] Jorion, P., and W. Goetzmann (1999), "Global Stock Markets in the Twentieth Century," *Journal of Finance* 54:953-980. Dimson, Marsh, and Staunton (2003) make a similar point when they comment on the equity risk premia for 16 countries based on returns between 1900 and 2001: "While the United States and the United Kingdom have indeed performed well, compared to other markets there is no indication that they are hugely out of line." p.4.

(2002) argues that 'we now have a bigger puzzle on our hands' Why have investors systematically biased their estimates over such a long horizon?"[14]

To sum up the above, I cite two passages from Profs. Mehra and Prescott's review of the theoretical literature on equity premium puzzle:[15]

> Even if the conditional equity premium given current market conditions is small, and there appears to be general consensus that it is, this in itself does not imply that it was obvious either that the historical premium was too high or that the equity premium has diminished.
>
> In the absence of this [knowledge of the future], and based on what we currently know, we can make the following claim: over the long horizon the equity premium is likely to be similar to what it has been in the past and the returns to investment in equity will continue to substantially dominate that in T-bills for investors with a long planning horizon.

Q9. Is there other scholarly support for the conclusion?

A9. Yes. Another line of research was pursued by Steven N. Kaplan and Richard S. Ruback. They estimate the market risk premium in their article, "The Valuation of Cash Flow Forecasts: An Empirical Analysis."[16] Professors Kaplan and Ruback compare published cash flow forecasts for management buyouts and leveraged recapitalization over the 1983 to 1989 period against the actual market values that resulted from these transactions. One of their results is an estimate of the market risk premium over the long-term Treasury bond yield that is based on careful analysis of actual major investment decisions, not realized market returns. Their median estimate is 7.78 percent and their mean estimate is 7.97 percent.[17] This is considerably higher than my estimate of 6.5 percent. Even if the maturity premium of Treasury bonds over Treasury bills were only 1 percent, well below the best estimate of 1.5 percent the resulting estimate of the market risk premium over Treasury bills is higher than my estimate of 8.0 percent.

[17] *Ibid*, p. 1082.

Q10. In addition to the scholarly articles and survey evidence you discussed in Section I of your Direct Testimony, what other evidence do you consider to estimate the MRP?

A10. I also consider the long-run realized equity premia reported in Morningstar *SBBI Valuation Edition 2007 Yearbook*. The data provided cover the period 1926 through 2006. The results are discussed below.

Q11. What is the "long-run realized risk premium" in the U.S.?

A11. From 1926 to 2006, the full period reported, Morningstar's data show that the average premium of stocks over Treasury bills is 8.6 percent. I also examine the "post-War" period. The risk premium for 1947-2006 is 8.4 percent.[18] (I exclude 1946 because its economic statistics are heavily influenced by the War years; e.g., the end of price controls yielded an inflation rate of 18 percent. It is not really a "post-War" year, from an economic viewpoint.) These averages often change slightly when another year of data is added to the Ibbotson series. The average premium of stocks over the income returns on long-term Government bonds is 7.1 percent for the 1926 to 2006 period and 7.1 for the 1947 to 2006 period.

Recently there has been a great deal of academic research on the MRP. This research has put practitioners in a dilemma: there is nothing close to a consensus about how the MRP should be estimated, but a general agreement in the academic community seems to be emerging that the old approach of using the average realized return over long periods gives too high an answer.

Q12. What is your conclusion regarding the MRP?

A12. Estimation of the MRP remains controversial. There is no consensus on its value or even how to estimate it. Given a careful review of all of the information, I estimate the risk premium for average risk stocks to be 8.0 percent over Treasury bills and 6.5 percent over long-term Government bonds.

[18] Morningstar, SBBI Valuation Edition 2007 Yearbook, Appendix A.

C. RELATIVE RISK

Q13. How do you measure relative risk?

A13. The risk measure I examine is the "beta" of the stocks in question. Beta is a measure of the "systematic" risk of a stock — the extent to which a stock's value fluctuates more or less than average when the market fluctuates. It is the most commonly used measure of risk in capital market theories.

Q14. Please explain beta in more detail.

A14. The basic idea behind beta is that risks that cannot be diversified away in large portfolios matter more than those that can be eliminated by diversification. Beta is a measure of the risks that *cannot* be eliminated by diversification.

Diversification is a vital concept in the study of risk and return. (Harry Markowitz won a Nobel Prize for work showing just how important it was.) Over the long run, the rate of return on the stock market has a very high standard deviation, on the order of 15 - 20 percent per year. But many individual stocks have much higher standard deviations than this. The stock market's standard deviation is "only" about 15 - 20 percent because when stocks are combined into portfolios, some of the risk of individual stocks is eliminated by diversification. Some stocks go up when others go down, and the average portfolio return — positive or negative — is usually less extreme than that of individual stocks within it.

In the limiting case, if the returns on individual stocks were completely uncorrelated with one another, the formation of a large portfolio of such stocks would eliminate risk entirely. That is, the market's long-run standard deviation would be not 15-20 percent per year, but virtually zero.

The fact that the market's actual annual standard deviation is so large means that, in practice, the returns on stocks are correlated with one another, and to a material degree. The reason is that many factors that make a particular stock go up or down also affect other stocks. Examples include the state of the economy, the balance of trade, and inflation. Thus some risk is "non-diversifiable". Single-factor equity risk premium

models derive conditions in which all of these factors can be considered simultaneously, through their impact on the market portfolio. Other models derive somewhat less restrictive conditions under which several of them might be individually relevant.

Again, the basic idea behind all of these models is that risks that cannot be diversified away in large portfolios matter more than those that can be eliminated by diversification, because there are a large number of large portfolios whose managers actively seek the best risk-reward tradeoffs available. Of course, undiversified investors would like to get a premium for bearing diversifiable risk, but they cannot.

Q15. Why not?

A15. Well-diversified investors compete away any premium rates of return for diversifiable risk. Suppose a stock were priced especially low because it had especially high diversifiable risk. Then it would seem to be a bargain to well diversified investors. For example, suppose an industry is subject to active competition, so there is a large risk of loss of market share. Investors who held a portfolio of all companies in the industry would be immune to this risk, because the loss on one company's stock would be offset by a gain on another's stock. (Of course, the competition might make the whole industry more vulnerable to the business cycle, but the issue here is the diversifiable risk of shifts in market share among firms.)

If the shares were priced especially low because of the risk of a shift in market shares, investors who could hold shares of the whole industry would snap them up. Their buying would drive up the stocks' prices until the premium rates of return for diversifiable risk were eliminated. Since all investors pay the same price, even those who are not diversified can expect no premium for bearing diversifiable risk.

Of course, substantial non–diversifiable risk remains, as the October Crash of 1987 demonstrates. Even an investor who held a portfolio of all traded stocks could not diversify against that type of risk. Sensitivity to such market–wide movements is what beta measures. That type of sensitivity, whether considered in a single- or multi-factor model, determines the risk premium in the cost of equity.

Q16. What does a particular value of beta signify?

A16. By definition, a stock with a beta equal to 1.0 has average non-diversifiable risk: it goes up or down by 10 percent on average when the market goes up or down by 10 percent. Stocks with betas above 1.0 exaggerate the swings in the market: stocks with betas of 2.0 tend to fall 20 percent when the market falls 10 percent, for example. Stocks with betas below 1.0 are less volatile than the market. A stock with a beta of 0.5 will tend to rise 5 percent when the market rises 10 percent.

Q17. How is beta measured?

A17. The usual approach to calculating beta is a statistical comparison of the sensitivity of a stock's (or a portfolio's) return to the market's return. Many investment services report betas, including Merrill Lynch's quarterly Security Risk Evaluation, Bloomberg and the *Value Line Investment Survey*. Betas are not always calculated the same way, and therefore must be used with a degree of caution, but the basic point that a high beta indicates a risky stock has long been widely accepted by both financial theorists and investment professionals.

Q18. Are there circumstances when the "usual approach to calculating beta" should not be used?

A18. There are at least two cases where the standard estimate of beta should be viewed skeptically.

First, companies in serious financial distress seem to "decouple" from their normal sensitivity to the stock market. The stock prices of financially distressed companies tend to change based more on individual news about their particular circumstances than upon overall market movements. Thus, a risky stock could have a low estimated beta if the company was in financial distress. Other circumstances that may cause a company's stock to decouple include an industry restructuring or major changes in a company's supply or output markets.

Second, similar circumstances seem to arise for companies "in play" during a merger or acquisition. Once again, the individual information about the progress of the proposed

takeover is so much more important for that stock than day-to-day market fluctuations that, in practice, beta estimates for such companies seem to be too low.

Q19. How reliable is beta as a risk measure?

A19. Scholarly studies have long confirmed the importance of beta for a stock's required rate of return. It is widely regarded as the best single risk measure available. The merits of beta seemed to have been challenged by widely publicized work by Professors Eugene F. Fama and Kenneth R. French.[19] However, despite the early press reports of their work as signifying that "beta is dead," it turns out that beta is still a potentially important explanatory factor (albeit one of several) in their work. Thus, beta remains alive and well as the best single measure of relative risk.

D. INTEREST RATE FORECAST

Q20. What interest rates do your procedures require?

A20. Modern capital market theories of risk and return use the short-term risk-free rate of return as the starting benchmark. My measures of the MRP incorporate this approach, since they represent the excess of the expected return on the market over the 30-day U.S. Treasury bill rate and over the long-term U.S. Government bond rate. Accordingly, implementation of my procedures requires use of a forecast of the 30-day Treasury bill rate and the long-term Government bond rate.

E. COST OF CAPITAL MODELS

Q21. How do you combine the above components into an estimate of the cost of capital?

A21. By far the most widely used approach to estimation of the cost of capital is the "Capital Asset Pricing Model," and I do calculate CAPM estimates. However, the CAPM is only one equity risk premium approach technique, and I also use another.

---

[19] See for example, "The Capital Asset Pricing Model: Theory and Evidence", Eugene F. Fama and Kenneth R. French, *Journal of Economic Perspectives*, Volume 18, Summer 2004, pp. 25-46.

Q22. Please start with the CAPM, by describing the model.

A22. As noted above, the modern models of capital market equilibrium express the cost of equity as the sum of a risk-free rate and a risk premium. The CAPM is the longest-standing and most widely used of these theories. The CAPM states that the cost of capital for investment *s* (e.g., a particular common stock) is given by the following equation:

$$k_s = r_f + \beta_s \times MRP \qquad \textbf{(C-1)}$$

where k_s is the cost of capital for investment *s*; r_f is the risk-free rate, β_s is the beta risk measure for the investment *s*; and *MRP* is the market risk premium.

The CAPM relies on the empirical fact that investors price risky securities to offer a higher expected rate of return than safe securities do. It says that the security market line starts at the risk-free interest rate (that is, that the return on a zero-risk security, the y-axis intercept in Figure 1 in the body of my testimony, equals the risk-free interest rate). Further, it says that the risk premium over the risk-free rate equals the product of beta and the risk premium on a value-weighted portfolio of all investments, which by definition has average risk.

Q23. What other equity risk premium approach model do you use?

A23. Empirical research has long shown that the CAPM tends to overstate the actual sensitivity of the cost of capital to beta: low-beta stocks tend to have higher risk premia than predicted by the CAPM and high-beta stocks tend to have lower risk premia than predicted. A number of variations on the original CAPM theory have been proposed to explain this finding. The difference between the CAPM and the type of relationship identified in the empirical studies is depicted in Figure MJV-C1.

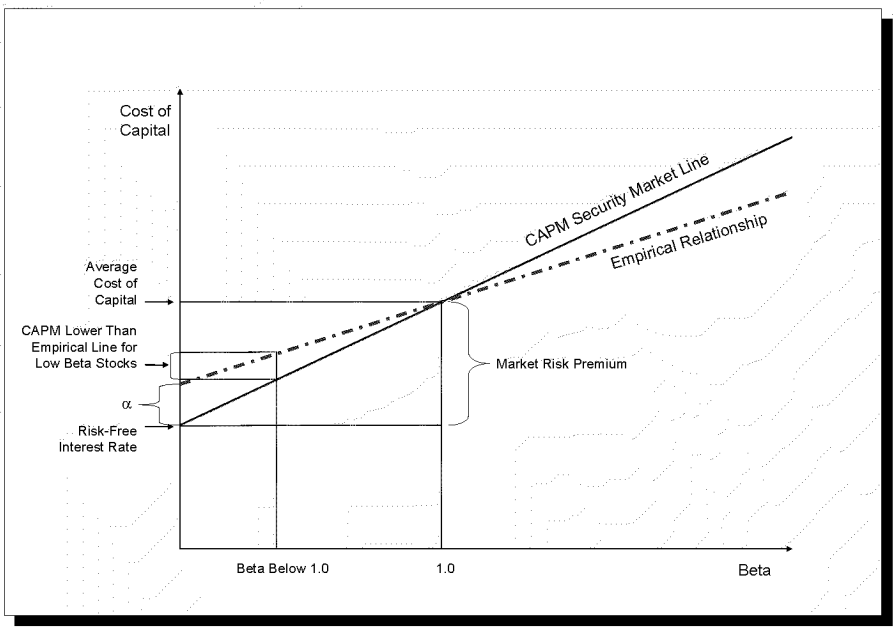

Figure MJV-C1: The Empirical Security Market Line

The second model makes use of these empirical findings. It estimates the cost of capital with the equation,

$$k_s = r_f + \alpha + \beta_s \times (MRP - \alpha) \qquad \textbf{(C-2)}$$

where α is the "alpha" of the risk-return line, a constant, and the other symbols are defined as above. I label this model the Empirical Capital Asset Pricing Model, or "ECAPM." For the short-term risk-free rate models, I set alpha equal to 1, 2, and 3 percent which are values somewhat lower than that estimated empirically. For low-beta stocks such as regulated utilities, the use of a lower value for alpha leads to a lower estimate of the cost of capital. For the long-term risk-free rate models, I set alpha equal to both 0.5 percent and 1.5 percent, but I rely more heavily on the 0.5 percent results. The use of a long-term risk-free rate incorporates some of the desired effect of using the ECAPM. That is, the long-term risk-free rate version of the Security Market Line has a higher intercept and a flatter slope than the short-term risk-free version which has been tested. Thus, it is likely that I do not need to make the same degree adjustment when I use the long-term risk-free rate. A summary of the empirical evidence on the magnitude of alpha is provided in Table No. MJV-C1 below.

II. EMPIRICAL EQUITY RISK PREMIUM RESULTS

Q24. How is this part of the appendix organized?

A24. This section presents the full details of my equity risk premium approach analyses, which are summarized in the body of my testimony. Details behind the forecasts of the short-term and the long-term risk-free interest rates are discussed. Next, the beta estimates, and the estimates of the MRP I use in the models are addressed. Finally, this section reports the CAPM and ECAPM results for the sample's costs of equity, and then describes the results of adjusting for differences between the benchmark sample and Dominion Virginia Power's regulated capital structures.

A. RISK-FREE INTEREST RATE FORECAST

Q25. How do you obtain the forecasts of the risk-free interest rates over the period the utility rates set here are to be in effect?

A25. I obtain these forecast rates using data provided by Bloomberg. In particular, I use their reported government debt yields from the "constant maturity series". This information is displayed in Panels A and B of Table No. MJV-9.

Q26. What values do you use for the short-term and long-term risk-free interest rates?

A26. I use a value of 4.1 percent for the short-term risk-free interest rate and a value of 5.1 percent for the long-term risk-free interest rate as the benchmark interest rates in the equity risk premium analyses. These forecasts are constructed by using historical yield curve data to find the long-run average implied term premia on government securities, and combining these with recent yield curve data. Details of their calculation can be found in the Workpapers to Table No. MJV-9.

B. Betas And The Market Risk Premium

1. Beta Estimation Procedures

Q27. How do you estimate beta?

A27. I use the beta estimates reported in the *Value Line* for the sample companies. The current *Value Line* beta estimates range from 0.70 to 1.30 for the benchmark sample (See Workpaper #1 to Table No. MJV-10).

2. Market Risk Premium Estimation

Q28. Given all of the evidence, what MRP do you use in your analysis?

A28. It is clear that market return information is volatile and difficult to interpret, but based on the collective evidence, the MRP I use for the short-term risk-free rate is 8 percent and for the long-term risk-free rate is 6.5 percent.

C. Cost Of Capital Estimates

Q29. Based on these data, what are the values you calculate for the overall cost of capital and the corresponding cost of equity for the sample?

A29. Panels A and B of Table No. MJV-10 present the cost of equity results using the equity risk positioning methods. Panel A uses the long-term risk-free rate forecast while Panel B uses the short-term risk-free rate forecast. These returns on equity are replicated and the overall cost of capital for the various equity risk positioning methods are reported in Table No. MJV-11, Panels A to G. Panels A through C utilize the long-term risk-free rate while Panels D through G use the short-term risk free rate. Panel A reports the cost of capital estimates using the CAPM results for the long-term risk-free rate, while Panels B and C report these estimates for the ECAPM cost of equity results using ECAPM parameters of 0.5 and 1.5 percent, respectively. Panel D reports the CAPM estimates using the short-term risk free rate, while Panels E, F and G report ECAPM results using ECAPM parameters of 1, 2 and 3 respectively. In each panel, column [8] reports the overall cost of capital for each company. The last row of each panel reports the sample and the subsample averages.

Q30. What does the sample market data imply about the sample's cost of equity at the proposed 50.7 percent equity ratio for Dominion Virginia Power Company?

A30. The sample average ATWACC from each panel of Table No. MJV-11 is reproduced in column [1] of Table No. MJV-12, which then reports the cost of equity for each of the risk positioning methods that is consistent with the sample information and the capital structure of Dominion Virginia Power. The sample average ATWACCs and corresponding costs of equity at a 50.7 percent equity ratio are also displayed in Table 3 of my testimony.

I discuss the implications of the equity risk positioning results for the sample in the main body of my testimony.

Table MJV-C1

EMPIRICAL EVIDENCE ON THE ALPHA FACTOR IN ECAPM*

AUTHOR	RANGE OF ALPHA	PERIOD RELIED UPON
Black (1993)[1]	1% for betas 0 to 0.80	1931-1991
Black, Jensen and Scholes (1972)[2]	4.31%	1931-1965
Fama and McBeth (1972)	5.76%	1935-1968
Fama and French (1992)[3]	7.32%	1941-1990
Litzenberger and Ramaswamy (1979)[4]	5.32%	1936-1977
Litzenberger, Ramaswamy and Sosin (1980)	1.63% to 3.91%	1926-1978
Pettengill, Sundaram and Mathur (1995)[5]	4.6%	1936-1990

*The figures reported in this table are for the longest estimation period available and, when applicable, use the authors' recommended estimation technique. Many of the articles cited also estimate alpha for sub-periods and those alphas may vary.

[1]Black estimates alpha in a one step procedure rather than in an un-biased two-step procedure.

[2]Estimate a negative alpha for the subperiod 1931-39 which contain the depression years 1931-33 and 1937-39.

[3]Calculated using Ibbotson's data for the 30-day treasury yield.

[4]Relies on Lizenberger and Ramaswamy's before-tax estimation results. Comparable after-tax alpha estimate is 4.4%.

[5]Pettengill, Sundaram and Mathur rely on total returns for the period 1936 through 1990 and use 90-day treasuries. The 4.6% figure is calculated using auction averages 90-day treasuries back to 1941 as no other series were found this far back.

II. EMPIRICAL DCF RESULTS D-8

A. PRELIMINARY MATTERS D-9
B. GROWTH RATES D-9
C. DIVIDEND AND PRICE INPUTS D-12
D. COMPANY-SPECIFIC DCF COST OF CAPITAL ESTIMATES D-13

Q1. What is the purpose of this appendix?

A1. This appendix reviews the principles behind the discounted cash flow or "DCF" methodology and the details of the cost of capital estimates obtained from this methodology.

I. DISCOUNTED CASH FLOW METHODOLOGY PRINCIPLES

Q2. How is this section of the appendix organized?

A2. The first part discusses the general principles that underlie the DCF approach. The second portion describes the strengths and weaknesses of the DCF model and why it is generally less reliable for estimating the cost of capital for the sample companies at the present time than the risk positioning method discussed in Appendix C.

A. SIMPLE AND MULTI-STAGE DISCOUNTED CASH FLOW MODELS

Q3. Please summarize the DCF model.

A3. The DCF model takes the first approach to cost of capital estimation discussed with Figure 1 in Section II-A of my direct testimony. That is, it attempts to measure the cost of equity in one step. The method assumes that the market price of a stock is equal to the present value of the dividends that its owners expect to receive. The method also assumes that this present value can be calculated by the standard formula for the present value of a cash flow stream:

$$P = \frac{D_1}{(1+k)} + \frac{D_2}{(1+k)^2} + \frac{D_3}{(1+k)^3} + \cdots + \frac{D_T}{(1+k)^T} \qquad \textbf{(D-1)}$$

where "P" is the market price of the stock; "D_i" is the dividend cash flow expected at the end of period i; "k" is the cost of capital; and "T" is the last period in which a dividend cash flow is to be received. The formula just says that the stock price is equal to the sum of the expected future dividends, each discounted for the time and risk between now and the time the dividend is expected to be received.

Most DCF applications go even further, and make very strong (*i.e.*, unrealistic) assumptions that yield a simplification of the standard formula, which then can be rearranged to estimate the cost of capital. Specifically, if investors expect a dividend stream that will grow forever at a steady rate, the market price of the stock will be given by a very simple formula,

$$P = \frac{D_1}{(k-g)} \qquad \textbf{(D-2)}$$

where "D_1" is the dividend expected at the end of the first period, "g" is the perpetual growth rate, and "P" and "k" are the market price and the cost of capital, as before. Equation D-2 is a simplified version of Equation D-1 that can be solved to yield the well known "DCF formula" for the cost of capital:

$$\begin{aligned} k &= \frac{D_1}{P} + g \\ &= \frac{D_0 \times (1+g)}{P} + g \end{aligned} \qquad \textbf{(D-3)}$$

where "D_0" is the current dividend, which investors expect to increase at rate g by the end of the next period, and the other symbols are defined as before. Equation D-3 says that if Equation D-2 holds, the cost of capital equals the expected dividend yield plus the (perpetual) expected future growth rate of dividends. I refer to this as the simple DCF model. Of course, the "simple" model is simple because it relies on very strong (*i.e.*, very unrealistic) assumptions.

Q4. Are there other versions of the DCF models besides the "simple" one?

A4. Yes. If Equation D-2 and its underlying assumptions do not hold, sometimes other variations of the general present value formula, Equation D-1, can be used to solve for k in ways that differ from Equation D-3. For example, if there is reason to believe that investors do *not* expect a steady growth rate forever, but rather have different growth rate forecasts in the near term (e.g., over the next five or ten years as compared with subsequent periods), these forecasts can be used to specify the early dividends in Equation D-1. Once the near-term dividends are specified, Equation D-2 can be used to

specify the share price value at the end of the near-term (e.g., at the end of five or ten years), and the resulting cash flow stream can be solved for the cost of capital using Equation D-1.

More formally, the "multi-stage" DCF approach solves the following equation for k:

$$P = \frac{D_1}{(1+k)} + \frac{D_2}{(1+k)^2} + \frac{D_3}{(1+k)^3} + \cdots + \frac{D_T + P_{TERM}}{(1+k)^T} \quad \textbf{(D-4)}$$

The terminal price, P_{TERM} is estimated as

$$P_{TERM} = \frac{D_{T+1}}{(k - g_{LR})} \quad \textbf{(D-5)}$$

where T is the last of the periods in which a near term dividend forecast is made and g_{LR} is the long-run growth rate. Thus, Equation D-4 defers adoption of the very strong perpetual growth assumptions that underlie Equation D-2 — and hence the simple DCF formula, Equation D-3 — for as long as possible, and instead relies on near term knowledge to improve the estimate of k. I examine both simple and multi-stage DCF results below.

Q5. What are the merits of the DCF model?

A5. The DCF approach is conceptually sound only if its assumptions are met. In actual practice one can run into difficulty because those assumptions are so strong, and hence so unlikely to correspond to reality. Two conditions are well-known to be necessary for the DCF approach to yield a reliable estimate of the cost of capital: the variant of the present value formula, Equation D-1, that is used must actually match the variations in investor expectations for the dividend growth path; and the growth rate(s) used in that formula must match current investor expectations. Less frequently noted conditions may also create problems.

The DCF model assumes that investors expect the cost of capital to be the same in all future years. Investors may not expect the cost of capital to be the same, which can bias the DCF estimate of the cost of capital in either direction.

The DCF model only works for companies for which the standard present value formula works. The standard formula does *not* work for companies that operate in industries or markets options (*e.g.*, puts and calls on common stocks), and so it will not work for companies whose stocks behave as options do. Option-pricing effects will be important for companies in financial distress, for example, which implies the DCF model will *understate* their cost of capital, all else equal.

In recent years even the most basic DCF assumption, that the market price of a stock in the absence of growth options is given by the standard present value formula (*i.e.*, by Equation D-1 above), has been called into question by a literature on market volatility.[1] In any case, it is still too early to throw out the standard formula, if for no other reasons than that the evidence is still controversial and no one has offered a good replacement. But the evidence suggests that it must be viewed with more caution than financial analysts have traditionally applied. Simple models of stock prices may not be consistent with the available evidence on stock market volatility.

Q6. Normally DCF debates center on the right growth rate. What principles underlie that choice?

A6. Finding the right growth rate(s) is indeed the usual "hard part" of a DCF application. The original approach to estimation of g relied on average historical growth rates in observable variables, such as dividends or earnings, or on the "sustainable growth" approach, which estimates g as the average book rate of return times the fraction of earnings retained within the firm. But it is highly unlikely that historical averages over periods with widely varying rates of inflation, interest rates and costs of capital, such as in the relatively recent past, will equal current growth rate expectations.

Fama and Kenneth R. French (2001), "Disappearing Dividends: Changing Firm Characteristics or Lower Propensity to Pay?," *Journal of Financial Economics*, Vol. 60, pp. 3-43. Borja Larrain and Motohiro Yogo (2005), "Does Firm Value

A better approach is to use the growth rates currently expected by investment analysts, if an adequate sample of such rates is available. If this approach is feasible and if the person estimating the cost of capital is able to select the appropriate version of the DCF formula, the DCF method should yield a reasonable estimate of the cost of capital for companies not in financial distress and without material option-pricing effects (always subject to recent concerns about the applicability of the basic present value formula to stock prices as well as issues of optimism bias). However, for the DCF approach to work, the basic stable-growth assumption must become reasonable and the underlying stable-growth rate must become determinable *within the period for which forecasts are available*.

Q7. What is the so called "optimism bias" in the earnings growth rate forecasts of security analysts and what is its effect on the DCF analysis?

A7. Optimism bias is related to the observed tendency for analysts to forecast earnings growth rates that are higher than are actually achieved. This tendency to over estimate growth rates is perhaps related to incentives faced by analysts that provide rewards not strictly based upon the accuracy of the forecasts. To the extent optimism bias is present in the analysts' earnings forecasts, the cost of capital estimates from the DCF model would be too high.

Q8. Does optimism bias mean that the DCF estimates are completely unreliable?

A8. No. The effect of optimism bias is least likely to affect DCF estimates for large, rate regulated companies in relatively stable segments of an industry. Furthermore, the magnitude of the optimism bias (if any) for regulated companies is not clear. This issue is addressed in a paper by Chan, Karceski, and Lakonishok (2003)[2] who sort companies on the basis of the size of the I/B/E/S forecasts to test the level of optimism bias. Utilities constitute 25 percent of the companies in lowest quintile, and by one measure the level of optimism bias is 4 percent. However, the 4 percent figure does not represent the

---

Move Too Much to be Justified by Subsequent Changes in Cash Flow?," Federal Reserve Bank of Boston, *Working Paper*, No. 05-18.

[2] L. K.C. Chan, J. Karceski, and J. Lakonishok, 2003, "The Level and Persistence of Growth Rates," *Journal of Finance* 58(2):643-684.

complete characterization of the results in the paper. Table IX of the paper shows that the median I/B/E/S forecast for the first (lowest) quintile averages 6.0 percent. The realized "Income before Extraordinary Items" is 2.0 percent (implying a four percent upward bias in I/B/E/S forecasts), but the "Portfolio Income before Extraordinary Items" is 8.0 percent (implying a two percent downward bias in I/B/E/S forecasts).

The difference between the "Income before Extraordinary Items" and "Portfolio Income before Extraordinary Items" is whether individual firms or a portfolio are used in estimating the realized returns. The first is a simple average of all firms in the quintile while the second is a market value weighted-average. Although both measures of bias have their own drawbacks according to the authors,[3] the Portfolio Income measure gives more weight to the larger firms in the quintile such as regulated utilities. In addition, the paper demonstrates that "analysts' forecasts as well as investors' valuations reflect a wide-spread belief in the investment community that many firms can achieve streaks of high growth in earnings."[4] Therefore, it is not clear how severe the problem of optimism bias may be for regulated utilities or even whether there is a problem at all.

Finally, the two-stage DCF model also adjusts for any over optimistic (or pessimistic) growth rate forecasts by substituting the long-term GDP growth rate for the 5-year growth rate forecasts of the analysts in the years beginning in year 11. I linearly trend the 5-year forecast growth rate to the GDP forecast growth rate in years 6 to 10.

Q9. What about the reforms by the National Associate of Security Dealers (NASD) that were designed to reduce the conflicts of interest and pressures brought against security analysts? Have those reforms been generally successful?

A9. Yes. The conclusion from the Joint Report by NASD and the New York Stock Exchange ("NYSE") on the reforms states

> … the SRO Rules have been effective in helping restore integrity to research by minimizing the influences of investment banking and promoting transparency of other potential conflicts of interest. Evidence

[3] Chan, Karceski, and Lakonishok, *op. cit.*, p. 675.

[4] Chan, Karceski, and Lakonishok, *op. cit.*, p. 663.

> also suggests that investors are benefiting from more balanced and accurate research to aid their investment decisions.[5]

The report does note additional reforms are advisable, but the situation is far different today than during the height of the tech bubble when analyst objectivity was clearly suspect.

B. CONCLUSIONS ABOUT DCF

Q10. Please sum up the implications of this part of the appendix.

A10. The unavoidable questions about the DCF model's strong assumptions — whether the basic present value formula works for stocks, whether option pricing effects are important for the company, whether the right variant of the basic formula has been found, and whether the true growth rate expectations have been identified — cause me to view the DCF method as *inherently* less reliable than equity risk premium approach, the other approach I use. However, because the DCF method has been widely used in the past and in other forums when the industry's economic conditions were different from today's, I submit DCF evidence in this case. DCF estimates also serve as a check on the values provided by the risk positioning approach methods.

II. EMPIRICAL DCF RESULTS

Q11. How is this part of the appendix organized?

A11. This section presents the details of my DCF analyses for the sample, which are summarized in my written testimony. The first part describes some preliminary matters, such as the calculation of market value capital structures of the sample companies and the determination of the growth rates. It then turns to the details of the DCF estimates themselves.

In particular, implementation of the simple DCF models described above requires an estimate of the current price, the dividend, and near-term and long-run growth rate

[5] Joint Report by NASD and NYSE on the Operation and Effectiveness of the Research Analyst Conflict of Interest Rules, December 2005, p. 44.

forecasts. The simple DCF model relies only on a single growth rate forecast, while the multistage DCF model employs both near-term individual company forecasts and long-run GDP growth rate forecasts. The remaining parts of this section describe each of these inputs in turn.

A. PRELIMINARY MATTERS

Q12. In Appendix C you discuss estimating cost of capital and implied cost of equity using the risk positioning methodology. What, if anything, is different when you use the DCF method?

A12. First, the timing of the market value capital structure calculations is different in the DCF method than in the equity risk premium method. The equity risk premium method relies on the average capital structure over the five-year period *Value Line* uses to estimate beta while the DCF approach uses only current data, so the relevant market value capital structure measure is the most recent that can be calculated. This capital structure is reported in columns [1]-[3] of Table No. MJV-4.

B. GROWTH RATES

Q13. What growth rates do you use?

A13. For reasons discussed above, historical growth rates today are generally unreliable as forecasts of current investor expectations for the electric utility industry. I therefore use rates forecasted by security analysts.

The ideal in a DCF application would be a detailed forecast of future dividends, year by year well into the future, based on a large sample of investment analysts' expectations. I know of no source of such data. Dividends are ultimately paid from earnings, however, and earnings forecasts are available for a few years. Investors do not expect dividends to grow in lockstep with earnings, but for companies for which the DCF approach can be used reliably (*i.e.*, for relatively stable companies whose prices do not include the option-like values described previously), they do expect dividends to track earnings over the long-run. Thus, use of earnings growth rates as a proxy for expectations of dividend growth rates is a common practice.

Accordingly, the first step in my DCF analysis is to examine a sample of investment analysts' forecasted earnings growth rates. In particular, I utilize Bloomberg's BEst and *Value Line's* forecasted earnings growth.[6] The projected earnings growth rates for the sample companies are in Table No. MJV-5.[7] Column [1] reports Bloomberg's BEst analysts' forecasts of the long-term earnings growth for the sample companies. Column [2] reports the number of analysts that provided a forecast. Columns [3] and [4] report *Value Line's* forecasted earnings per share ("EPS") value for each company for 2008 and 2010-2012 respectively. Column [5] provides *Value Line's* implied long-term growth rate forecast, and column [6] provides a weighted average growth rate for each company across the two sources. (I treat the *Value Line* forecasts as though they overlap exactly with the forecasts from Bloomberg.) These growth rates underlie my simple and multi-stage DCF analyses.

In particular, the five-year average annual growth rate is the perpetual growth rate I employ in the simple DCF model.[8] In the multi-stage model, I rely on the company-specific growth rate until 2012 and on the long-term GDP forecast for year 2018 onwards. During the years from 2013 to 2017, I assume the growth rate converges linearly towards the long-term GDP forecast.[9]

Q14. Do these growth rates correspond to the ideal you mentioned above?

A14. No, not completely. While forecasted growth rates are the quantity required in principle, the forecasts need to go far enough out into the future so that it is reasonable to believe that investors expect a stable growth path afterwards. As can be seen from Table No. MJV-5, the growth rate estimates do not support the view that investors are expecting growth rates equal to the single perpetual growth rate assumed in the simple DCF model. Indeed, there is substantial variation across companies' combined growth rates. For

---

[6] The BEst growth rates were downloaded from Bloomberg on June 11, 2007. *Value Line* estimates are from the most recent reports available, variously dated March 30, 2007, May 11, 2007, and June 1, 2007. (See Table No. MJV-5.)

[7] No Bloomberg BEst growth rate was available for MGE Energy Inc. at this time.

[8] This growth rate is in column [6] of Table No. MJV-5.

[9] I use the long-term U.S. GDP growth estimate from *Blue Chip Economic Indicators* (March 10, 2007).

example, Entergy and PPL each have a combined growth rate estimate of over 10 percent, while Consolidated Edison's and Pinnacle West's combined estimates are both 3.4 percent (see column [6], Table No. MJV-5).

It should be noted that except for MGE Energy, there are at least two analyst estimates for all of the sample companies, though Cleco Corp and Empire Electric have only two. The comparison between the average growth rate forecasts and the growth in GDP forecast indicates that these growth rates may be overly optimistic in the case of some electric companies.

Q15. How well are the conditions needed for DCF reliability met at present?

A15. The requisite conditions for the sample companies are not fully met at this time. Of particular concern for this proceeding is the uncertainty about what investors truly expect the long-run outlook for the sample companies to be. The longest time period available for growth rate forecasts of which I am aware is five years. The long-run growth rate (*i.e.*, the growth rate after the energy industry settles into a steady state, which is certainly *beyond* the next five years for this industry) drives the actual results one gets with the DCF model. Unfortunately, this implies that unless the company or industry in question is stable, so there is little doubt as to the growth rate investors expect. DCF results in practice can end up being driven by the subjective judgment of the analyst who performs the work.

This is a problem at present because it is hard to imagine that today's energy industry would accurately be described as stable. Inflation and interest rates have largely stabilized over the last ten years, but oil and natural gas prices have increased dramatically. The prices of natural gas and petroleum have also exhibited a great deal of volatility recently. These factors make demand for natural gas and electricity more uncertain. The electric industry (as well as both the pipeline industry and the gas distribution sector) are going through a series of mergers and acquisitions, which affects the companies' earnings growth rate estimates. This is one reason why companies heavily involved in mergers and acquisitions are normally excluded from the sample. A number of states are actively considering reversing the restructuring process for the

electric utility industry. There has also been financial distress among companies specializing in trading natural gas and electricity products which affects both regulated and unregulated companies. Taken together, these factors mean that it may be some time before the energy industry settles into anything investors will see as a stable equilibrium.

Such circumstances imply that a regulator may often be faced with a wide range of DCF numbers, none of which can be well grounded in objective data on true long-run growth expectations, *because no such objective data now exist*. DCF for firms or industries in flux is *inherently* subjective with regard to a parameter (the long-run growth rate) that drives the answer one gets.

It is clear that much longer detailed growth rate forecasts than currently available from Bloomberg and *Value Line* would be needed to implement the DCF model in a completely reliable way for the sample at this time.

C. DIVIDEND AND PRICE INPUTS

Q16. What values do you use for dividends and stock prices?

A16. Dividends are the last recorded dividend payments as reported by Bloomberg, the 1st-quarter 2007 dividend. This dividend is grown at the estimated growth rate and divided by the price described below to estimate the dividend yield for the simple and multi-stage DCF models.

For the sample calculations, stock prices are the average of the closing stock prices for the 15 trading days (approximately three weeks) ending May 9, 2007 for each company, the most recent data available on the date the growth rate estimates were downloaded from Bloomberg. I do not use a longer period to measure the price, because that would be inconsistent with the principles that underlie the DCF formula. The DCF approach assumes the stock price is the present value of future expected dividends. Stock prices six months or a year ago reflect expectations at that time, which are different from those that underlie the currently available growth forecasts. At the same time, use of an average over a brief period helps guard against a company's price on a particular day

price being unduly influenced by the release of information on a particular day, differences in trading frequency, and the like.

The closing stock price is used because it is at least as good as any other measure of the day's outcome, and may be better for DCF purposes. In particular, if there were any single price during the day that would affect investors' decisions to buy or sell a stock, I would suspect that it would be each day's closing price, not the high or low during the day. The daily price changes reported in the financial pages, for example, are from close to close, not from high to high or from low to low.

D. COMPANY-SPECIFIC DCF COST OF CAPITAL ESTIMATES

Q17. What DCF estimates do these data yield?

A17. The cost of equity results for the simple and multistage DCF models are shown in Table No. MJV-6. Panel A reports the results for the simple DCF method while Panel B reports the results for the multistage DCF method using the long-term GDP growth rate as the perpetual growth rate.

Q18. What overall cost of capital estimates result from the DCF cost of equity estimates?

A18. The capital structure, DCF cost of equity, and cost of debt estimates are combined to obtain the overall after-tax weighted-average cost of capital for each sample company. These results are presented in Table No. MJV-7. Again, Panel A relies on the simple DCF cost of equity results while Panel B relies on the multistage DCF cost of equity results.

Q19. What information do you report in Table No. MJV-8?

A19. This table reports the return on equity consistent with the sample's estimated overall after-tax weighted-average cost of capital and the proposed equity thickness of 50.7 percent for Dominion Virginia Power. For both the simple DCF and multistage DCF methods, the sample's average ATWACC is reported in column [1]. Column [6] reports the return on equity as if the sample companies' average market value capital structure had been that currently proposed for Dominion Virginia Power.

Q20. What are the implications of these results?

A20. The implication of these numbers is discussed in my written testimony, along with the findings of the equity risk premium approach.

APPENDIX E

EFFECT OF DEBT ON THE COST OF EQUITY

I. AN OVERVIEW OF THE ECONOMIC LITERATURE E-2

A. TAX EFFECTS E-2
1. Base Case: No Taxes, No Risk to High Debt Ratios E-3
2. Corporate Tax Deduction for Interest Expense E-4
3. Personal Tax Burden on Interest Expense E-5

B. NON-TAX EFFECTS E-8

II. EXPANDED EXAMPLE E-12

A. DETAILS OF DIFFERENT LEVELS OF DEBT E-12

B. THE IMPACT OF INCOME AND INTEREST E-16

C. THE EFFECT OF TAXES E-19

D. COMBINED EFFECTS E-24

Q1. What is the purpose of this Appendix?

A1. In this appendix, I provide details on the effects of debt on the cost of equity. First, I summarize a fairly large body of financial research on capital structure. Second, I provide an extended example to illustrate the effect of debt on the cost of equity.

I. AN OVERVIEW OF THE ECONOMIC LITERATURE

Q2. What is the focus of the economic literature on the effects of debt?

A2. The economic literature focuses on the effects of debt on the value of a firm. The standard way to recognize one of these effects, the impact of the fact that interest expense is tax-deductible, is to discount the all-equity after-tax operating cash flows generated by a firm or an investment project at a weighted average cost of capital, typically known in textbooks as the "WACC." The textbook WACC equals the *market*-value weighted average of the cost of equity and the *after-tax*, *current* cost of debt. However, rate regulation in North America has a legacy of working with another weighted-average cost of capital, the *book*-value weighted average of the cost of equity and the *before-tax*, *embedded* cost of debt. To distinguish the concepts, I refer to the after-tax weighted-average cost of capital as ATWACC.

Q3. How is this section of the appendix organized?

A3. It starts with the tax effects of debt. It then turns to other effects of debt.

A. TAX EFFECTS

Q4. What are the key findings in the literature regarding tax effects?

A4. Three seminal papers are vital for this literature. The first assumes no taxes and risk-free debt. The second adds corporate income taxes. The third adds personal income taxes.

1. Base Case: No Taxes, No Risk to High Debt Ratios

Q5. Please start by explaining the simplest case of the effect of debt on the value of a firm.

A5. The "base case," no taxes and no costs to excessive debt, was worked out in a classic 1958 paper by Franco Modigliani and Merton Miller, two economists who eventually won Nobel Prizes in part for their body of work on the effects of debt.[1] Their 1958 paper made what is in retrospect a very simple point: if there are no taxes and no risk to the use of excessive debt, use of debt will have no effect on a company's operating cash flows (i.e., the cash flows to investors as a group, debt plus equity combined). If the operating cash flows are the same regardless of whether the company finances mostly with debt or mostly with equity, then the value of the firm cannot be affected at all by the debt ratio. In cost of capital terms, this means the overall cost of capital is constant regardless of the debt ratio, too.

In the base case, issuing debt merely divides the cash flows into two pools, one for bondholders and one for shareholders. If the divided pools have different priorities in claims on the cash flows, the risks and costs of capital will differ for each pool. But the risk and overall cost of capital of the entire firm, the sum of the two pools, is constant regardless of the debt ratio. Thus,

$$r_1^* = r_{A1} \qquad \text{(E-1a)}$$

where r^*_1 is the overall after-tax cost of capital at any particular capital structure and r_{A1} is the all-equity cost of capital for the firm. (The "1" subscripts distinguish the case where there are no taxes from subsequent equations that consider first corporate and then both corporate and personal taxes.) With no taxes and no risk to debt, the overall cost of capital does not change with capital structure.

This implies that the relationship of the overall cost of capital to the component costs of debt and equity is

[1] Franco Modigliani and Merton H. Miller (1958), "The Cost of Capital, Corporation Finance and the Theory of Investment," *American Economic Review*, 48, pp. 261-297.

$$r_{E1} \times \left(\frac{E}{V}\right) + r_{D1} \times \left(\frac{D}{V}\right) = r_1^* \qquad \text{(E-1b)}$$

with the overall cost of capital (r^*) on the *right* side, as the *independent* variable, and the costs of equity (r_E) and debt (r_D) on the left side, as *dependent* variables determined by the overall cost of capital and by the capital structure (i.e., the shares of equity (E) and debt (D) in overall firm value (V=E+D)) that the firm happens to choose. Note that if equation (E-1a) were correct, the equation that solved it for the cost of equity would be,

$$r_{E1} = r_1^* + (r_1^* - r_D) \times \left(\frac{D}{E}\right) \qquad \text{(E-1c)}$$

Note also that (D/E) gets exponentially higher in this equation as the debt-to-value ratio increases[2] i.e., the cost of equity increases exponentially with leverage.

2. Corporate Tax Deduction for Interest Expense

Q6. What happens when you add corporate taxes to the discussion?

A6. If corporate taxes exist with risk-free debt (and if only taxes at the corporate level matter, not taxes at the level of the investor's personal tax return), the initial conclusion changes. Debt at the corporate level reduces the company's tax liability by an amount equal to the marginal tax rate times interest expense. All else equal, this will add value to the company because more of the operating cash flows will end up in the hands of investors as a group. That is, if only corporate taxes mattered, interest would add cash to the firm equal to the corporate tax rate times the interest expense. This increase in cash would increase the value of the firm, all else equal. In cost of capital terms, it would reduce the overall cost of capital.

How much the value of the firm would rise and *how far* the overall cost of capital would fall would depend in part on how often the company adjusts its capital structure, but this is a second-order effect in practice. (The biggest effect would be if companies could issue riskless perpetual debt, an assumption Profs. Modigliani and Miller explored in

[2] For example, at 20-80, 50-50, and 80-20 debt-equity ratios, (D/E) equals, respectively, (20/80) = 0.25, (50/50) = 1.0, and (80/20) = 4.0. The extra 30 percent of debt going from 20-80 to 50-50 has much less impact on (D/E) [i.e., by moving it from 0.25 to 1.0] than the extra 30 percent of debt going from 50-50 to 80-20 [i.e., by moving it from 1.0 to 4.0]. Since the cost of equity equals a constant risk premium times the debt-equity ratio, the cost of equity grows ever more rapidly as you add more and more debt.

1963, in the second seminal paper;[3] this assumption could *not* be true for a real company.) Prof. Robert A. Taggart provides a unified treatment of the main papers in this literature and shows how various cases relate to one another.[4] Perhaps the most useful set of benchmark equations for the case where only corporate taxes matter are:

$$r_2^* = r_{A2} - r_D \times t_C \times \left(\frac{D}{V}\right) \quad \text{(E-2a)}$$

$$r_2^* = r_{E2} \times \left(\frac{E}{V}\right) + r_D \times \left(\frac{D}{V}\right) \times (1 - t_C) \quad \text{(E-2b)}$$

which imply for the cost of equity,

$$r_{E2} = r_{A2} + (r_{A2} - r_D) \times \left(\frac{D}{E}\right) \quad \text{(E-2c)}$$

where the variables have the same meaning as before but the "2" subscripts indicate the case that considers corporate but not personal taxes.

Note that Equation (E-2a) implies that when only corporate taxes matter, the overall after-tax cost of capital declines steadily as more debt is added, until it reaches a minimum at 100 percent debt (i.e., when D/V = 1.0). Note also that Equation (E-2c) still implies an exponentially increasing cost of equity as more and more debt is added. In fact, except for the subscript, Equation (E-2c) looks just like Equation (E-1c).

However, whether any value is added and whether the cost of capital changes at all also depends on the effect of taxes at the personal level.

3. Personal Tax Burden on Interest Expense

Q7. How do personal taxes affect the results?

A7. Ultimately, the purpose of investment is to provide income for consumption, so personal taxes affect investment returns. For example, in the U.S., municipal bonds have lower interest rates than corporate bonds because their income is taxed less heavily at the

---

[4] Robert A. Taggart, Jr. (1991), "Consistent Valuation and Cost of Capital Expressions with Corporate and Personal Taxes," *Financial Management* 20, pp. 8-20.

personal level. In general, capital appreciation on common stocks is taxed less heavily than interest on corporate bonds because (1) taxes on unrealized capital gains are deferred until the gains are realized, and (2) the capital gains tax rate is lower. Dividends are taxed less heavily than interest, also, under current tax law.[5] The effects of personal taxes on the cost of common equity are hard to measure, however, because common equity is so risky.

Professor Miller, in his Presidential Address to the American Finance Association,[6] explored the issue of how personal taxes affect the overall cost of capital. The paper pointed out that personal tax effects could offset the effect of corporate taxes entirely.

Q8. Is it likely that the effect of personal taxes will completely neutralize the effect of corporate taxes?

A8. I do not believe so, although the likelihood of such a result would be increased if the current federal tax reductions on dividends and capital gains became permanent rather than expiring in 2010. However, personal taxes are important even if they do not make the corporate tax advantage on interest vanish entirely. Capital gains and dividend tax advantages definitely convey some personal tax advantage to equity, and even a partial personal advantage to equity reduces the corporate advantage to debt.

The Taggart paper explores the case of a partial offset, also. With personal taxes, the risk-free rate on the security market line is the after-personal-tax rate, which must be equal for risk-free debt and risk-free equity.[7] Therefore, the pre-personal-tax risk-free rate for equity will generally not be equal to the pre-personal-tax risk-free rate for debt. In particular, $r_{fE} = r_{fD} \times [(1-t_D)/(1-t_E)]$, where r_{fE} and r_{fD} are the risk-free costs of equity and debt and t_E and t_D are the personal tax rates for equity and debt, respectively. In

[5] The current maximum personal tax rate on dividend income was extended to the end of 2010 by the President on May 17, 2006. It is uncertain whether the reduced rates on dividend income will be further extended.

[6] Merton H. Miller (1977), "Debt and Taxes," *The Journal of Finance*, 32: 261-276, the third of the seminal papers mentioned earlier.

[7] As Prof. Taggart notes (his footnote 9), it is not necessary that a specific, risk-free equity security exist as long as one can be created synthetically, through a combination of long and short sales of traded assets. Such constructs are a common analytical tool in financial economics.

terms of the cost of debt, the Taggart paper's results imply that a formal statement of these effects can be written as:[8]

$$r_3^* = r_{A3} - r_D \times t_N \times \left(\frac{D}{V}\right) \quad \text{(E-3a)}$$

$$= r_{E3} \times \left(\frac{E}{V}\right) + r_D \times \left(\frac{D}{V}\right) \times (1 - t_C) \quad \text{(E-3b)}$$

which imply

$$r_{E3} = r_{A3} + \left[r_{A3} - r_D \times \left(\frac{1 - t_D}{1 - t_E}\right)\right] \times \left(\frac{D}{E}\right) \quad \text{(E-3c)}$$

Suppose, for example, that t_C = 0.35 percent, t_E = 7.7 percent and t_D = 40 percent. Then $[(1-t_D)/(1-t_E)] = 0.65 = (1-t_C)$. That condition corresponds to Miller's 1977 paper, in which the net personal tax advantage of equity fully offsets the net corporate tax advantage of debt. Note also that in that case, $t_N = 0$.[9] Therefore, if the personal tax advantage on equity fully offsets the corporate tax advantage on debt, Equation (E-3a) confirms that the overall after-tax cost of capital is a constant.

However, it is unlikely that the personal tax advantage of equity fully offsets the corporate tax advantage of debt. If taxes were all that mattered (i.e., if there were no other costs to debt), the overall after-corporate-tax cost of capital would still fall as debt was added, just not as fast.

Finally, note that the overall after-tax cost of capital, Equation (E-3b), still uses the corporate tax rate even when personal taxes matter. Equations (E-2b) and (E-3b) both correspond to the usual formula for the ATWACC. Personal taxes affect the way the cost of equity changes with capital structure -- Equation (E-3c) -- but not the formula for the overall after-tax cost of capital given that cost of equity.

---

[8] The net all-tax effect of debt on the overall cost of capital, t_N, equals $\{[t_C+t_E-t_D-(t_C \times t_E)] / (1-t_E)\}$, where t_D is the personal tax rate on debt, as before. This measure of net tax effect is designed for use with the cost of debt in Equation (E-3a), which seems more useful in the present context. The Taggart paper works with a similar measure, but one which is designed for use with the cost of risk-free equity in the equivalent Taggart equation.

[9] In the above example, $t_N = \{[0.35+0.077-0.4-(0.35 \times 0.077)] / (1.0-0.077)\} = 0.0/0.923 = 0$.

B. NON-TAX EFFECTS

Q9. Please describe the non-tax effects of Debt.

A9. If debt is truly valuable, firms should use as much as possible, and competition should drive firms in a particular industry to the same, optimal capital structure for the industry. If debt is harmful on balance, firms should avoid it. Neither picture corresponds to what we actually see. A large economic literature has evolved to try to explain why.

Part of the answer clearly is the costs of excessive debt. Here the results cannot be reduced to equations, but they are no less real for that fact. As companies add too much debt, the costs come to outweigh the benefits. Too much debt reduces or eliminates financial flexibility, which cuts the firm's ability to take advantage of unexpected opportunities or weather unexpected difficulty. Use of debt rather than internal financing may be taken as a negative signal by the market.

Even if the company is generally healthy, more debt increases the risk that the company cannot use all of the interest tax shields in a bad year. As debt continues to grow, this problem grows and others may crop up. Management begins to worry about meeting debt payments instead of making good operating decisions. Suppliers are less willing to extend trade credit, and a liquidity shortage can translate into lower operating profits. Ultimately, the firm might have to go through the costs of bankruptcy and reorganization. Collectively, such factors are known as the costs of "financial distress."[10]

The net tax advantage to debt, if positive, is affected by costs such as a growing risk that the firm might have to bear the costs of financial distress. First, the expected present value of these costs offsets the value added by the interest tax shield. Second, since the likelihood of financial distress is greater in bad times when other investments also do poorly, the possibility of financial distress will increase the risks investors bear. These effects increase the variability of the value of the firm. Thus, firms that use too much debt can end up with a higher overall cost of capital than those that use none.

[10] See, for example, Section 18.3 of Brealey, Myers and Allen, 2006, *Principles of Corporate Finance*, 8th Edition, McGraw-Hill/Irwin, 2006.

Other parts of the answer include the signals companies send to investors by the decision to issue new securities, and by the type of securities they issue. Other threads of the literature explore cases where management acts against shareholder interests, or where management attempts to "time" the market by issuing specific securities under different conditions. For present purposes, the important point is that no theory, whether based on taxes or on some completely different issue, has emerged as "the" explanation for capital structure decisions by firms. Nonetheless, despite the lack of a single "best" theory, there is a great deal of relevant empirical research.

Q10. What does that research show?

A10. The research does not support the view that debt makes a material difference in the value of the firm, at least not once a modest amount of debt is in place. If debt were truly valuable, competitive firms should use as much debt as possible short of producing financial distress, and competitive firms that use less debt ought to be less profitable. The research shows exactly the opposite.

For example, Kester[11] found that firms in the same industry in both the U.S. and Japan do not band around a single, "optimal" capital structure, and the most profitable firms are the ones that use the *least* debt. This finding comes despite the fact that both countries at the time (unlike the U.S. currently) had fully "classical" tax systems, in which dividends are taxed fully at both the corporate and personal level. Wald[12] confirms that high profitability implies low debt ratios in France, Germany, Japan, the U.K., and the U.S. Booth *et al.* find the same result for a sample of developing nations.[13] Fama and French[14] analyze over 2000 firms for 28 years (1965-1992, inclusive) and conclude, "Our tests

[12] John K. Wald (1999), "How Firm Characteristics Affect Capital Structure: An International Comparison," *Journal of Financial Research*, 22:161-167.

[13] Laurence Booth *et al.* (2001), "Capital Structures in Developing Countries," *The Journal of Finance* Vol. LVI, pp. 87-130, finds at p. 105 that "[o]verall, the strongest result is that profitable firms use less total debt. The strength of this result is striking ..."

[14] Eugene F. Fama and Kenneth R. French (1998), "Taxes, Financing Decisions and Firm Value," *The Journal of Finance*, 53:819-843.

thus produce no indication that debt has net tax benefits."[15] A paper by Graham[16] carefully analyzes the factors that might have led a firm not to take advantage of debt. It confirms that a large proportion of firms that ought to benefit substantially from use of additional debt, including large, profitable, liquid firms, appear not to use it "enough."

This research leaves us with only three options: either (1) apparently good, profit-generating managers are making major mistakes or deliberately acting against shareholder interests, (2) the benefits of the tax deduction on debt are less than they appear, or (3) the non-tax costs to use of debt offset the potential tax benefits. Only the first of these possibilities is consistent with the view that the tax deductibility of debt conveys a material cost advantage. Moreover, if the first explanation were interpreted to mean that otherwise good managers are acting against shareholder interests, either deliberately or by mistake, it would require the additional assumption that their competitors (and potential acquirers) let them get away with it.

Q11. Are there any explanations in the financial literature for this puzzle other than stupid or self-serving managers at the most profitable firms?

A11. Yes. For example, Stewart C. Myers, a leading expert on capital structure, made it the topic of his Presidential Address to the American Finance Association.[17] The poor performance of tax-based explanations for capital structure led him to propose an entirely different mechanism, the "pecking order" hypothesis. This hypothesis holds that the net tax benefits of debt (i.e., corporate tax advantage over personal tax disadvantage) are at most of a second order of importance relative to other factors that drive actual debt decisions.[18] Similarly, Baker and Wurgler (2002)[19] observe a strong and persistent

[18] See also Stewart C. Myers (1989), "Still Searching for Optimal Capital Structure," *Are the Distinctions Between Debt and Equity Disappearing?,* R.W. Kopke and E. S. Rosengren, eds., Federal Reserve Bank of Boston.

[19] Malcolm Baker and Jeffrey Wurgler (2002), "Market Timing and Capital Structure," *The Journal of Finance* 57:1-32.

impact that fluctuations in market value have on capital structure. They argue that this impact is not consistent with other theories. The authors suggest a new capital structure theory based on market timing -- capital structure is the cumulative outcome of attempts to time the equity market.[20] In this theory, there is no optimal capital structure, so market timing financing decisions just accumulate over time into the capital structure outcome. (Of course, this theory only makes sense if investors do not recognize what managers are doing.)

Q12. Do inter-firm differences within an industry explain the wide variations in capital structure across the firms in an industry?

A12. No. This view is contradicted by the empirical research. As mentioned before, it has long been found that the most profitable firms in an industry, i.e., those in the best position to take advantage of debt, use the least.[21] Graham (2000) carefully examines differences in firm characteristics as possible explanations for why firms use "too little" debt and concludes that such differences are *not* the explanation: firms that ought to benefit substantially from more debt by all measurable criteria, if the net tax advantage of debt is truly valuable, voluntarily do not use it.[22]

Nor does the research support the view that firms are constantly trying to adjust their capital structures to optimal levels. Additional research on the pecking order hypothesis demonstrates that firms do not tend towards a target capital structure, or at least do not do so with any regularity, and that past studies that seemed to show the contrary actually lacked the power to distinguish whether the hypothesis was true or not.[23] In the words of

---

[20] *Ibid.*, p. 29.

[21] For example, Kester, *op. cit.* and Wald, *op. cit.*

[22] While not contradicting Graham's finding that differences in firm characteristics do not explain capital structure differences, Nengjiu Ju, Robert Parrino, Allen M. Poteshman, and Michael S. Weisbach, "Horses and Rabbits? Trade-Off Theory and Optimal Capital Structure," *Journal of Financial and Quantitative Analysis*, June 2005, pp. 1-24, looks at the issue in a different manner. Their paper uses a dynamic rather than static model to analyze the tradeoff between the tax benefits of debt and the risk of financial distress. It finds that bankruptcy costs by themselves are enough to explain observed capital structures, once dynamic effects are considered. This means debt is not as valuable as suggested by the traditional static analysis (of the sort used by Graham).

the Shyam-Sunder - Myers paper p. 242, "If our sample companies did have well-defined optimal debt ratios, it seems that their managers were not much interested in getting there."

II. EXPANDED EXAMPLE

Q13. What topics do you cover in this section?

A13. The discussion in my testimony did not detail the impact of different starting points for the level of debt nor did it address income earned on the investment, interest expense, or taxes. This section covers these topics. First, it discusses how the level of debt affects the cost of equity. Second, it addresses the influence of income and interest on the investment. Third, it explains the impact of taxes on capital structure decisions. The final topic covered in this section is the combined consequence of tax and non-tax effects of debt.

A. DETAILS OF DIFFERENT LEVELS OF DEBT

Q14. Why does more debt mean more risk for equity holders?

A14. Debt magnifies the variability of the equity return. As a simple example, think of an investor who takes money out of her savings and invests $100,000 in real estate. The future value of the real estate is uncertain. If the real estate market booms, she wins. If the real estate market goes down, she loses. Figure E-1 below illustrates this.

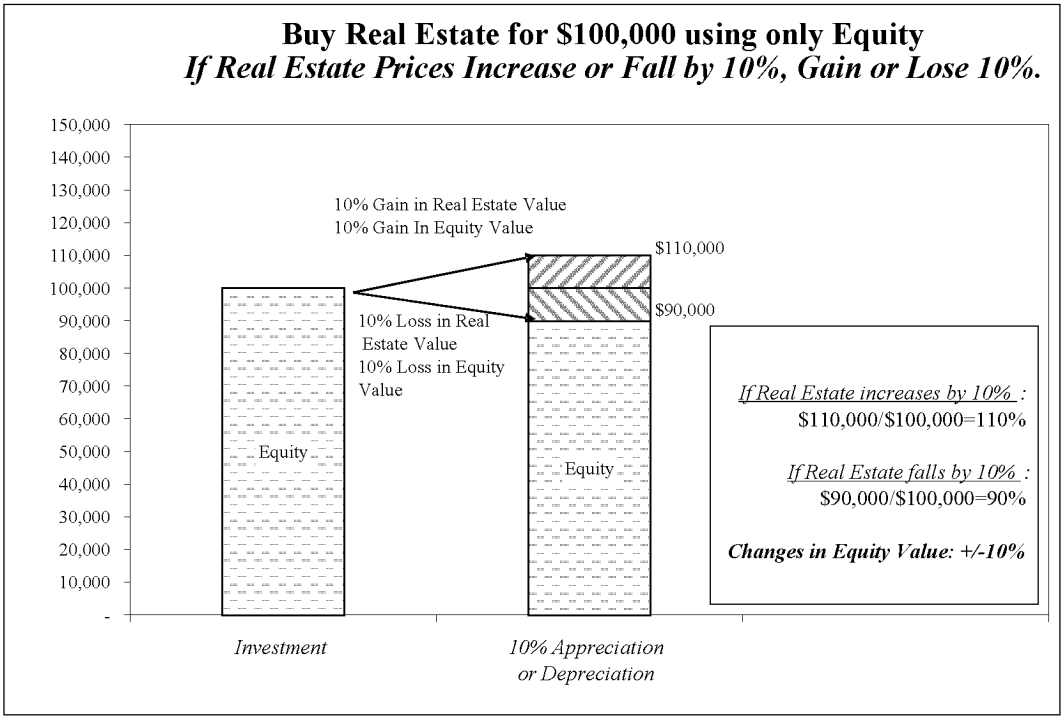

Figure E-1

In the scenario above, the investor financed her real estate purchase through 100 percent equity. Suppose instead that the investor had financed 50 percent of her real estate investment with a mortgage of $50,000. The mortgage lender does not expect to share in any benefits from increases in real estate values. Neither does the mortgage lender expect to share in any losses from falling real estate values, i.e., the investor carries the entire risk of fluctuating real estate prices. Figure E-2 illustrates this effect.

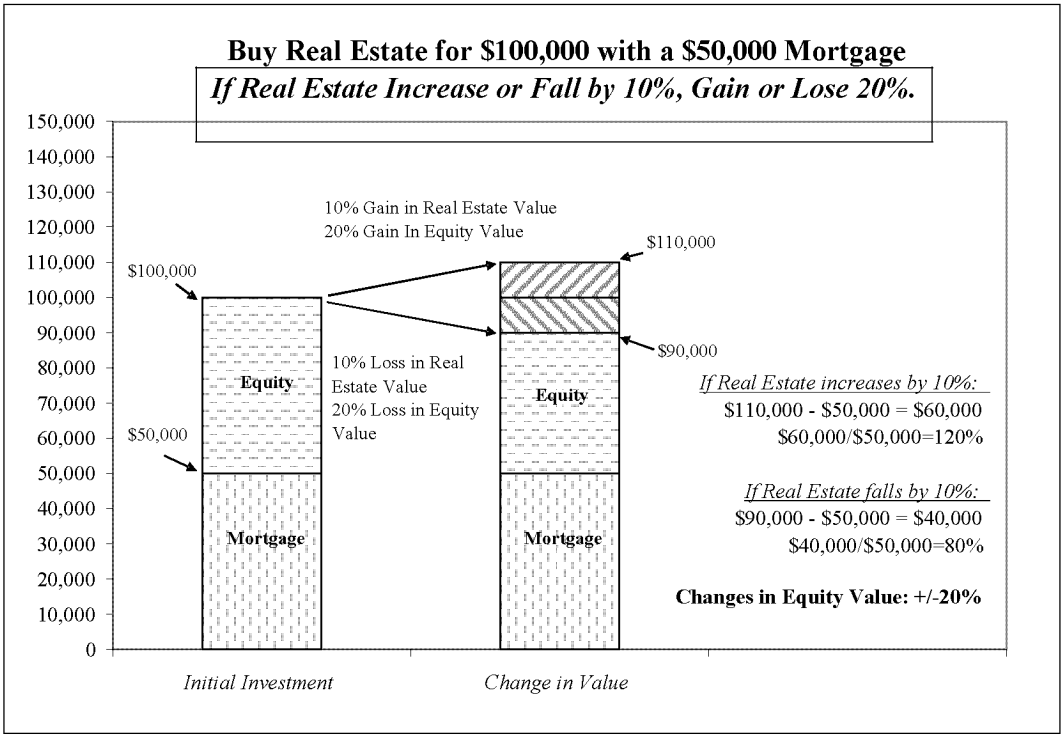

Figure E-2

In Figure E-2 where the investor financed her purchase through 50 percent equity and 50 percent debt, the variability in the investor's equity return is two times greater than that of Figure E-1. The entire fluctuation of 10 percent from rising or falling real estate prices falls on the investor's $50,000 equity investment. The lesson from the example is obvious, debt adds risk to equity.

Q15. What happens if the investor finances the real estate purchase with different proportions of debt?

A15. The equity return becomes more variable when the mortgage percentage is a greater proportion of the initial price. Table E-1 below calculates the return on equity when real estate prices increase by 10 percent when mortgages are 0 percent, 30 percent, 50 percent, and 70 percent of the initial price.

Table E-1: The Impact of Leverage on the Return on Equity

	100% Equity	70% Equity	50% Equity	30% Equity
Debt	$0	$30,000	$50,000	$70,000
Original Equity Investment	$100,000	$70,000	$50,000	$30,000
Increase in Market Value of Equity	$10,000	$10,000	$10,000	$10,000
Return on Equity Investment	10%	14.3%	20%	33.3%

Note that going from 70 percent equity down to 50 percent equity increases the return on the equity investment by 5.7 percent while going from 50 percent equity to 30 percent equity increases the return on equity by 13.3 percent. This illustrates a general point; the rate of return on equity increases more quickly at higher levels of debt than at lower levels. Investors demand a higher equity rate of return to bear more risk and debt magnifies equity's risk at an ever increasing rate. Therefore, the required equity rate of return goes up at an ever increasing rate as debt is added. This is not only basic finance theory, it is the everyday experience of anyone who buys a home. The bigger the mortgage, the more percentage risk the equity faces from changes in housing prices.

Q16. Please provide an example that illustrates why market values are relevant.

A16. Suppose in the above example that the investor has invested in real estate 10 years ago. Further assume that depreciation has reduced the book value of the real estate from $100,000 to $75,000 and assume the investor has paid off 40 percent of his $50,000 mortgage. Thus, the investor has a remaining mortgage of $30,000 (= 60% × $50,000). The book value of the investor's equity investment is therefore $45,000 (= $75,000 - $30,000).

What happens now if real estate prices rise or fall 20 percent? To answer that question, we need to know how real estate prices have developed over the past 10 years. If the market value of the real estate now is $200,000 then a 20 percent decrease in the price of real estate ($40,000) is almost equal to the investor's book value equity. However, his

market value equity (or net worth) is equal to the value of the real estate minus what he owes on the mortgage. If we assume that the market value of the mortgage equals the unpaid balance ($30,000), then the investor's net worth is calculated as follows:

Net Worth	=	Market Value of Real Estate	-	Remaining Mortgage
	=	$200,000	-	$30,000
	=	$170,000		

Therefore, the rate of return on equity due to a 20 percent decline in real estate prices is calculated in Table E-2.

Table E-2: Calculating the Rate of Return on Equity

Decline in Real Estate Value	$40,000
Market-Value Equity	$170,000
Rate of Return on Equity	- $40,000/$170,000 = -23.5%

B. THE IMPACT OF INCOME AND INTEREST

Q17. How does earning income from the investment and paying interest on debt affect the results?

A17. In the following explanation, I ignore income taxes which I deal with in Section C below. Assume the investor is receiving income, e.g., rent, from the real estate. Specifically, assume the investor receives $500 per month in income after all non-interest expenses ($6,000 per year). Also, assume that the expected appreciation is 5 percent per year, so the expected market value is $105,000 after one year. Then the expected rate of return from the real estate with all equity financing is:

$$\text{Expected Return on Equity @ 0\% debt} = \frac{\text{Expected Net Income + Expected Appreciation}}{\text{Initial Investment}}$$

$$= \frac{\$6{,}000 + (\$105{,}000 - \$100{,}000)}{\$100{,}000}$$

$$= 11\%$$

Now suppose that the mortgage interest rate were 5 percent. Then at a mortgage equal to 50 percent, or $50,000, interest expense would be ($50,000 x 0.05), or $2,500. The expected equity rate of return would be:

$$\text{Expected Return on Equity @ 50\% debt} = \frac{\text{Expected (Net Income + Appreciation) – Int. Expense}}{\text{Initial } \textit{Equity} \text{ Investment}}$$

$$= \frac{\$6{,}000 + \$5{,}000 - \$2{,}500}{\$50{,}000}$$

$$= 17\%$$

Notice that the expected return on equity is higher as is the risk carried by equity.

Q18. Can you provide a more general illustration?

A18. Yes. Figure E-3 uses these assumptions at different mortgage levels to plot both (i) the expected rate of return on the equity in the dwelling, and (ii) the realized rate of return on

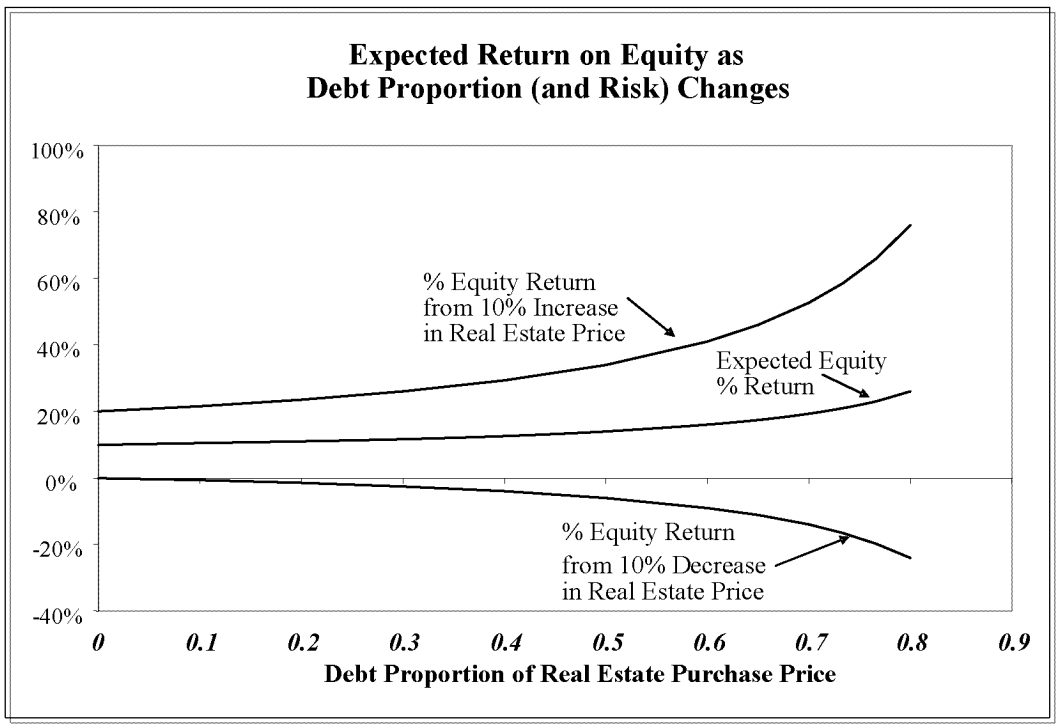

Figure E-3

that equity in a year if the dwelling value increases by 10 percent more than the expected 5 percent rate (i.e., if the value increases by 15 percent) or by 10 percent less than expected (i.e., if it decreases by 5 percent).[24]

The expected rate of return on equity increases at an increasing rate as the investor finances more and more of the real estate through loans (e.g., with a mortgage). Since equity bears all the risk of increases or decreases in real estate values (absent financial distress or bankruptcy), the amount of risk the buyer bears grows at an ever increasing rate as the mortgage percentage also increases.

Q19. What are the implications of this example?

A19. Any time an individual or a company uses debt to finance part an investment, the same risk magnifies. For example, if an investor buys stocks "on margin" -- by borrowing part of the money used to buy the stock -- the expected rate of return will be higher as will the risks the investor carries. As an everyday example, imagine investing your retirement

[24] For simplicity, the figure assumes the debt's interest rate is independent of the debt proportion. This might not always be true, and in general would not be true for a corporation that issued debt. However, the general shape of the graphs remains the same.

savings in a stock portfolio bought with as much margin as possible. If you were lucky, you could end up living very well in retirement. But you would be taking a lot of risk on the opposite outcome, since your portfolio could decline by more than 100 percent of your initial investment.

The same risk-magnifying effects happen when companies borrow to finance part of their investments.

C. THE EFFECT OF TAXES

Q20. What is the impact of taxes?

A20. Analyzing the net effect of taxes in capital structure decisions by corporations is an important part of the financial research. (Other parts of that research address such issues as the risk of financial distress or bankruptcy, and the signals corporations send investors by the choice of how to finance new investments.) The bottom line is that taxes complicate the picture without changing the basic conclusion.

Q21. Please describe the potential impact of taxes.

A21. Interest expense is tax-deductible for corporations. That increases the pool of cash the corporation gets to keep out of its operating earnings (i.e., its earnings before interest expense). With no debt, 100 percent of operating income is subject to taxes. With debt, only the equity part of the operating income is subject to taxes.

All else equal, the extra money kept from operating income increases the value of the corporation. The standard way to recognize that increase in value is to use an after-tax weighted-average cost of capital as a discount rate when valuing a company's operating cash flows.

Q22. Do personal taxes affect the value of debt, too?

A22. Yes, but in the other direction. One offset to debt's tax benefits at the corporate level is its higher tax burden at the personal level. Investors care about the money they get to keep after all taxes are paid, and while the corporation saves taxes by opting for debt over

equity, individuals pay more taxes on interest than on capital gains from equity (and for now, on dividends as well).

Q23. Are there factors other than taxes matter?

A23. Absolutely, "all else" does not remain equal as more debt is added. The more debt, the more the non-tax effects of debt offset the tax benefits. Other costs include such effects as a loss of flexibility, the possibility of sending negative signals to investors, and a host of costs and risks associated with the danger of financial distress.

Q24. Does the tradeoff between the tax and non-tax effects of debt mean that firms have well-defined, optimal capital structures?

A24. No, this sort of "tradeoff" model does not explain actual corporate behavior. A substantial body of economic research confirms that real-world corporations act as if, after a moderate amount of debt is in place, the tax benefits of debt are not worth debt's other costs. In country after country and in industry after industry, the most profitable corporations in an industry tend to use the least debt. The research on this point is quite thorough, and the finding that the most profitable companies tend to use the least debt in a given industry is robust. Yet these are the companies with the most operating income to shield from taxes, who would benefit most if interest tax shields were truly valuable net of debt's other costs. They also presumptively are the best-managed on average (else why are they the most profitable?). This means it is unrealistic to suppose that more debt is always better, or that greater tax savings due to higher interest expense always add value to the firm on balance.

Q25. If the tradeoff model doesn't explain capital structure decisions by firms, is there a model that does?

A25. No single model has (yet) emerged as 'the" explanation of capital structure. However, several alternative models attempt to model the tradeoff (e.g., the "pecking order" hypothesis and "agency cost" explanations).

Q26. What does the absence of an agreed theory of capital structure in the financial literature imply about the overall effect of debt on the value of the firm?

A26. The findings of the financial literature mean that within an industry, there is no well-defined optimal capital structure. The use of some debt does convey some value advantage in most industries, but that advantage is offset by other costs as firms add more debt.[25] The range of capital structures over which the value of the firm in any industry is maximized is wide and should be treated as flat. The location and level of that range, however, does vary from industry to industry, just as the overall cost of capital varies from industry to industry.

Figure E-4 illustrates the picture that emerges from the research. This figure shows the present value of an investment in each of four different industries. For simplicity, the investment is expected to yield $1.00 per year forever. For firms in relatively high-risk industries (Industry 1 in the graph, the lowest line), the $1.00 perpetuity is not worth much and any use of debt decreases firm value. For firms in relatively low-risk industries (Industry 4 in the graph), the perpetuity is worth more and substantial amounts of debt make sense. Industries 2 and 3 are intermediate cases.

The maximum net rate at which taxes can increase value in this figure equals 20 percent of interest expense, representing a balance between the corporate tax advantage to debt and the personal tax disadvantage. The figure plots the maximum possible impact of taxes on value as a separate line, starting at the all-equity value of the lowest-risk industry (Industry 4).

[25] Note that if debt did increase the value of the firm materially, competition would tend to take that value away, since issuing debt is an easy-to-copy competitive strategy. Prices would fall as firms copied the strategy, lowering operating earnings and passing the net tax advantages to debt through to customers (just as happens under rate regulation). Therefore, if also there were a narrow range of optimal capital structures within an industry, competition would drive all firms in the industry to capital structures within that range. This does not happen in practice, which contradicts one or both of the assumptions, i.e., (1) that debt adds material value on balance, and/or (2) that there is a narrow range of optimal capital structures.

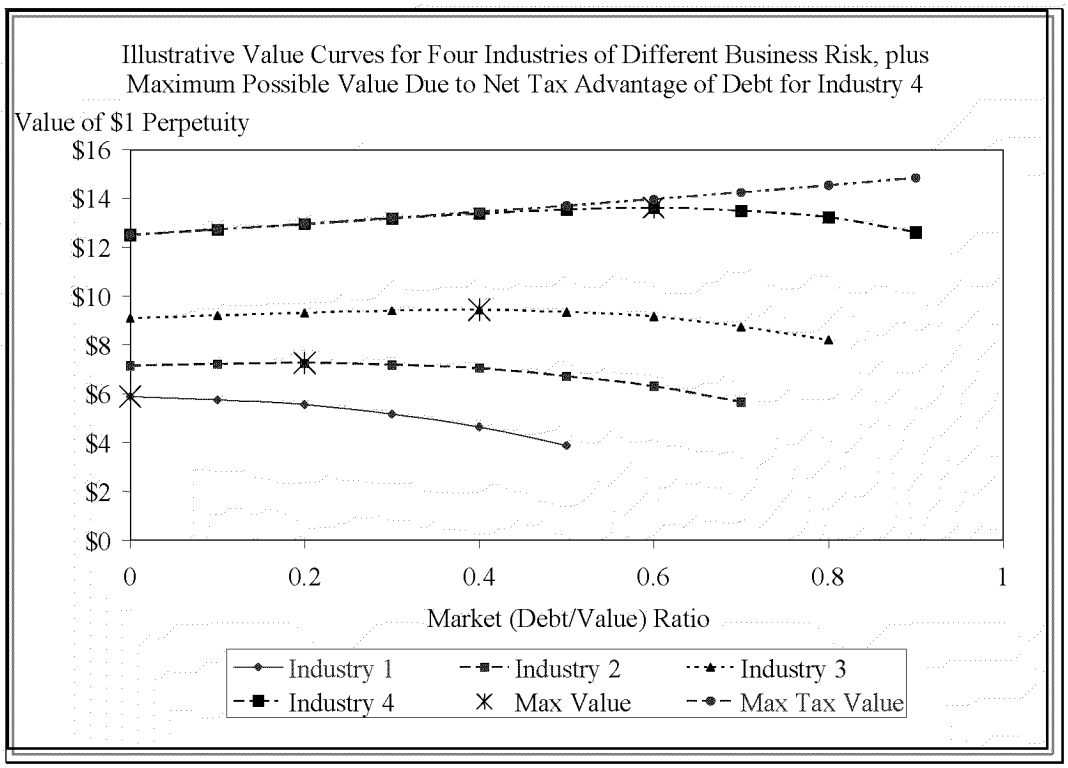

Figure E-4

Figure E-4 identifies a particular point as the maximum value on each of the four curves. However, the research shows that reliable identification of this maximum point, except in the extreme case where no debt should be used, is impossible. In accord with the research, the graph is prepared so that in none of the industries does a change in capital structure make much difference near the top of the curve. Even Industry 4, which increases in value at the maximum rate as quite a lot of debt is added, eventually must reach a broad range where changes in the debt ratio make little difference to firm value, given the research. For Industry 4, debt makes less than a 2 percent difference in the total value of the firm for debt-to-value ratios between 40 and 70 percent. (While these particular values are illustrative, numbers of this order of magnitude are the only ones consistent with the research.)

Q27. What does this imply for the overall cost of capital?

A27. Figure E-5 plots the after-tax weighted-average costs of capital ("ATWACCs") that correspond to the value curves in Figure E-4. This picture just turns Figure E-4 upside

down.[26] All the same conclusions remain, except that they are stated in terms of the overall cost of capital instead of the overall firm value. In particular, except for high-risk industries, the overall cost of capital is essentially flat across a broad middle range of capital structures for each industry, which is the only outcome consistent with the research. For Industry 4, for example, the ATWACC changes by less than 15 basis points for debt-to-value ratios between 40 and 70 percent.

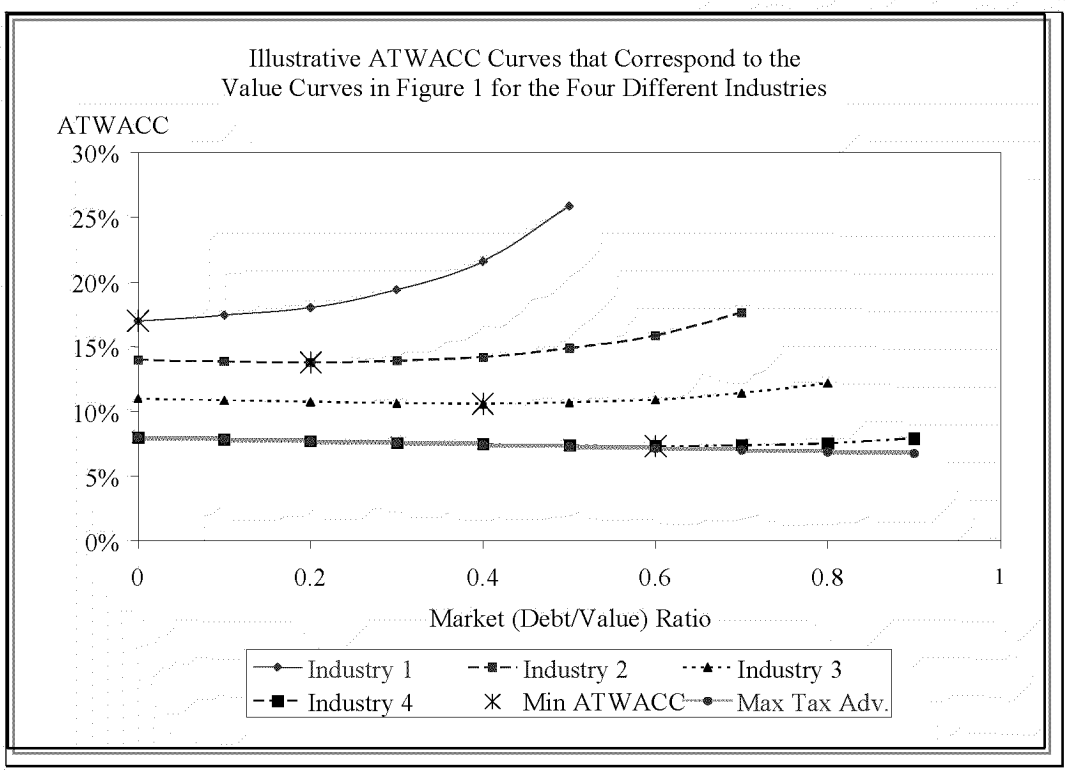

Figure E-5

Q28. How does this discussion relate to estimation of the right cost of equity for ratemaking purposes?

A28. When an analyst estimates the cost of equity for a sample of companies, s/he does so at the sample's actual market-value capital structure. That is, the sample evidence corresponds to ATWACCs that are already out somewhere in the broad middle range in

[26] Note that the actual estimated ATWACC at higher debt ratios will tend to underestimate the ATWACC that corresponds to the value curves in Figure E-4, which are depicted in Figure E-5, and so will tend to overestimate the value of debt to the firm. The reason is that some of the non-tax effects of excessive debt, such as a loss of financial flexibility, may be hard to detect and not show up in cost of capital measurement.

which changes in the debt ratio have little or no impact on the overall value of the firm or the ATWACC.

An analyst therefore should assume the ATWACCs for the sample companies are literally flat. This assumption always provides the exact tradeoff between the cost of equity and capital structure at the literal minimum of the company's ATWACC curve. The research shows that this minimum is actually a broad, flat region, as depicted above. If the company happens to be somewhat to one side or the other of the literal minimum within this region, the recommended procedure may lead to a small understatement or overstatement of the amount that the cost of equity will change as capital structure changes. The degree of this under- or overstatement, however, is very small compared to the inherent uncertainty in estimating the cost of equity in the first place. Otherwise, the financial research would have found very different results about the existence of a narrowly defined optimal capital structure.

D. COMBINED EFFECTS

Q29. Please summarize the implications for the combined impact of the tax and non-tax effects of debt.

A29. The most profitable firms do not behave as if the precise amount of debt they use makes any material difference to value, and competition does not force them into an alternative decision, as it would if debt were genuinely valuable. The explanation that fits the facts and the research is that within an industry, there is no well-defined optimal capital structure. Use of some debt does convey an advantage in most industries, but that advantage is offset by other costs as firms add more debt. The range of capital structures over which the value of the firm in any industry is maximized is wide and should be treated as flat. The location and level of that range, however, does vary from industry to industry, just as the overall cost of capital varies from industry to industry. To conclude that more debt does add more value, once the firm is somewhere in the normal range for the industry, is to conclude that corporate management in general is either blind to an easy source of value or otherwise incompetent (and that their competitors let them get away with it).

The finding that there is no narrowly defined optimal capital structure implies that analysts should estimate the ATWACCs for a sample of companies in a given industry and treat the average ATWACC value as independent of capital structure (at least within a broad middle range of capital structures). The right cost of equity for a rate-regulated company in the same industry is the number that yields the same ATWACC at the capital structure used to set the revenue requirement, since that is the cost of equity that (estimation problems aside) the sample companies would have had if their market-value capital structures had been equal to the regulatory capital structure.

V.	CONCLUSIONS		36

I. INTRODUCTION AND SUMMARY

Q1. Please state your name and address for the record.

A1. My name is Michael J. Vilbert. My business address is The Brattle Group, 44 Brattle Street, Cambridge, MA 02138.

Q2. Please describe your job and your educational experience.

A2. I am a Principal of The Brattle Group, ("Brattle"), an economic, environmental and management consulting firm with offices in Cambridge, Washington, London, San Francisco and Brussels. My work concentrates on financial and regulatory economics. I hold a B.S. from the U.S. Air Force Academy and a Ph.D. in finance from the Wharton School of Business at the University of Pennsylvania. Appendix A of my direct testimony contains additional information on my professional qualifications.

Q3. Did you previously file testimony in this proceeding?

A3. Yes, I filed direct testimony ("Vilbert Direct") on behalf of Virginia Electric and Power Company ("Dominion Virginia Power" or the "Company") in July 2007 regarding the return on equity that Dominion Virginia Power should be allowed an opportunity to earn on the equity financed portion of its assets.

Q4. What is the purpose of your rebuttal testimony?

A4. I have been asked by Dominion Virginia Power to respond to Mr. Michael Gorman, who filed testimony ("Gorman Testimony") on behalf of Virginia Committee for Fair Utility Rates ("VCFUR"), and to Mr. Lawrence T. Oliver, who filed testimony ("Oliver Testimony") on behalf of the Staff of the State Corporation Commission ("Commission Staff" or "Staff"). Specifically, I will be responding to their recommendations for the allowed return on equity for Dominion Virginia Power and Mr. Gorman's recommended

reduction in the equity percentage of Dominion Virginia Power's regulatory capital structure.

Q5. What rate of return on equity does VCFUR witness Gorman recommend?

A5. Mr. Gorman recommends placing the rate of return at what he deems to be a "floor" return on equity of 10.2%, as prescribed by his unique interpretation of the methodologies set forth in Va. Code § 56-585.1.A.2. At the same time, he also recommends that Dominion Virginia Power's debt ratio be increased by 7.25 percentage points to 52% total debt including short-term debt and off-balance sheet liabilities. On a regulatory capital structure basis, the increase in total debt is to 50.4%. Assuming this entire increase comes from a reduction in common equity (instead of preferred), he is recommending an equity return of 10.2% on a capital structure with approximately 43.6% equity, if short-term debt were considered. The recommended reduction in both equity return and equity thickness represents a substantial increase in financial risk for the Company, as well as a large decrease in earnings.

Q6. What allowed return on equity does Staff witness Oliver recommend?

A6. Mr. Oliver considers the overall cost of capital resulting from equity returns of 10, 11, 12 and 13%, but he recommends a 10% return on equity based upon a range of 9.5 to 10.5% derived from the cost of equity estimation models. Unlike VCFUR witness Gorman, Mr. Oliver endorses the Company's filed capital structure and does not recommend any change.

Q7. How is the rest of your rebuttal organized?

A7. In *Section II,* I address the issue of capital structure and financial risk. In particular, I discuss Mr. Gorman's mistreatment of the concept of financial risk. For example,

financial risk is a function of the market value, not book value, capital structure. I also discuss Mr. Gorman's and Mr. Oliver's misunderstanding of the after-tax weighted-average cost of capital ("ATWACC") approach used in my direct testimony to adjust for differences in financial risk. Failure to recognize differences in financial risk represents a material error in both Mr. Gorman's and Mr. Oliver's approaches. In *Section III,* I review Mr. Gorman's cost of equity estimates and note several errors and questionable assumptions, all of which have the effect of reducing the allowed return on equity for Dominion Virginia Power. I also note several problems with Mr. Oliver's implementation of the models. In *Section IV,* I explain why applying the Empirical Capital Asset Pricing Model ("ECAPM") is appropriate even when using adjusted betas from *Value Line. Section V* contains my conclusions.

II. FINANCIAL RISK AND CAPITAL STRUCTURE

Q8. What does this section of your rebuttal address?

A8. First, I will discuss financial risk and how it is properly measured by reference to a company's market value capital structure as opposed to its book value capital structure. Then, I will explain how the ATWACC approach addresses the issue of differences in financial risk among the sample companies and why the ATWACC approach is not a market-to-book value adjustment. Finally, I will demonstrate that credit risk is not a measure of equity risk as asserted by the VCFUR witness Gorman.

A. Financial Risk is Based on Market Value not Book Value Capital Structures

Q9. Before you begin a discussion of financial risk, please clarify some terminology. Mr. Gorman defines business risks as non-systematic risks?[1] Is this definition standard in finance?

A9. No. Normally business risk is defined as the market risk of the assets of a company that uses no debt in its capital structure. In other words, it is the systematic risk of the assets. Diversifiable risk is sometimes referred to as company unique risk or non-systematic risk. In the following, I use the standard definition of business risk, as opposed to the one used by Mr. Gorman.

Q10. Does Mr. Gorman recognize financial risk?

A10. Yes. He claims to recognize the importance of financial risk,[2] but appears to misunderstand the concept.

Q11. What is financial risk?

A11. Financial risk is the additional risk shifted to equity holders from the use of debt in a company's capital structure. Changing a company's capital structure by replacing equity with debt increases the risk that remaining equity holders bear. This is because debt holders are paid a fixed payment stream first before any payments are available to equity holders, but the total risk of the assets is unchanged. As the percentage of equity in the capital structure shrinks, more of the residual risk is left to be shouldered by a smaller equity base.

---

[1] The Pre-filed Testimony and Exhibits of Michael Gorman, on behalf of Virginia Committee for Fair Utility Rates, filed on November 2, 2007 ("Gorman Testimony"), p. 30.

[2] See, *e.g.*, Gorman Testimony, p. 11.

Q12. Why do you say that Mr. Gorman appears to misunderstand the concept of financial risk?

A12. Mr. Gorman's characterization of financial risk is flawed in a fundamental sense.[3] He evaluates the financial risk of his sample based on *book-value* capital structures. This is a mistake. There is no debate in financial theory that financial risk is defined in terms of market value capital structures. It is not defined in terms of book value capital structures. Mr. Gorman has certainly provided no academic reference suggesting that financial risk is measured by book value capital structures.

Q13. What is the evidence that VCFUR witness Gorman relies on book value capital structures to evaluate financial risk?

A13. Mr. Gorman considers the percentage of equity in the book-value capital structures of the companies in his sample and determines that it is on average somewhat lower than that of Dominion Virginia Power's regulatory capital structure. He then incorrectly asserts that financial risk is actually higher for the sample companies than for Dominion Virginia Power.[4] This turns the concept of financial risk on its head. The financial risk (and the cost of capital) for the sample companies is determined in the market place using market values and not by the companies accounting books.

Q14. How does Staff witness Oliver measure financial risk?

A14. Mr. Oliver agrees with Mr. Gorman's assessment of the relative financial risk of the Company to the sample, although he is not specific as to the basis for that assessment.[5]

---

[3] Gorman Testimony, pp. 16-18.

[4] Gorman Testimony, p. 17.

[5] The Pre-Filed Testimony of Lawrence T. Oliver, Division of Economics & Finance, on behalf of the Virginia State Corporation Commission, filed on November 28, 2007, ("Oliver Testimony"), p. 29.

Mr. Oliver references Va. Code § 56-585.1.A.2, but that section discusses setting the "floor" return on equity and does not appear to address the issue of financial risk of the Company. In the following, I assume that Mr. Oliver's assessment is based upon the same or similar considerations as Mr. Gorman.

Q15. Can you provide textbook references indicating that market value capital structures are the correct measure of financial risk?

A15. Yes. This is a well-accepted concept in financial theory. See, for example, Richard A. Brealey, Stewart C. Myers, and Franklin Allen, *Principles of Corporate Finance*, New York: McGraw-Hill/Irwin 8th edition (2006). In discussing financial risk on pages 503-506, the authors say "Why did we show the book value balance sheet? Only so you draw a big X through it. Do so now."[6] As another example, see "The Effect of the Firm's Capital Structure on the Systematic Risk of Common Stock," by Robert S. Hamada in *The Journal of Finance*, 1972, which relies on market value capital structures to adjust for differences in financial leverage.

B. THE ATWACC APPROACH IS NOT A MARKET-TO-BOOK VALUE ADJUSTMENT

Q16. What does this section of your rebuttal address?

A16. I will discuss how the ATWACC approach implemented in my direct testimony addresses differences in financial risk. I will then attempt to clear up the confusion resulting from Mr. Gorman's and Mr. Oliver's misunderstanding of the ATWACC approach. Both testimonies reject any recognition of the differences in financial risk

[6] Brealey, Myers and Allen, *op cit.*, p. 504.

between the sample companies and the Company at its regulated capital structure, and both incorrectly characterize the ATWACC approach as a market-to-book adjustment.

Q17. Is the ATWACC approach a market-to-book adjustment in disguise?

A17. No. The ATWACC approach is *not* a market-to-book adjustment. It is critical to understand this point. If the ATWACC approach is to be accepted or rejected by the Commission, it should be because of what the approach actually recommends and not because it has been incorrectly characterized as a market-to-book adjustment. The following explains the distinction.

Q.18 Mr. Oliver's objection to the ATWACC approach is direct. He simply notes that "investors are well aware of the prevalent and long-standing regulatory practice of applying market based cost of equity estimates to book value equity."[7] How do you respond?

A18. In the U.S., Mr. Oliver's observation is certainly true, although not universally so. For example, the Surface Transportation Board relies upon market value capital structures to estimate the "revenue adequacy" of the railroads it regulates.[8] However, Mr. Oliver does not address the correctness of the fundamental financial theory underlying the ATWACC method. If the theory underlying the ATWACC is recognized as being correct, as I believe that it certainly should be, then rejecting the approach should require more analysis than in essence, "it is different from the way it has always been done." In his objection to the ATWACC approach, Staff witness Oliver also points to market-to-book ratios greater than 1.0 for the companies in the sample as evidence that the allowed

[7] Oliver Testimony, p. 26.

[8] Surface Transportation Board Decision, STB Ex Parte No. 558 (Sub-No. 9), decided on December 19, 2005.

returns on equity must be adequate.[9] However, I do not believe that the current market-to-book ratios are evidence one way or the other of the adequacy of the allowed rate of return on equity for the sample companies. I address this point in more detail below.

Q19. Please review the ATWACC approach and the specific errors made by Mr. Gorman in his critique of the methodology.

A19. The fundamental premise of the ATWACC approach is that the risk of the assets of a company is divided between the debt holders and equity holders, i.e., the company's investors.[10] Mr. Gorman seems to agree with this point.[11] When estimating the cost of equity using the standard models, the estimated cost of equity reflects both the business risk and the financial risk of the sample company, based upon the sample company's *market value* capital structure. There is no academic debate on this point. In particular, note that if the market value capital structure were different, the estimated cost of equity would be different as well because of the difference in financial risk.

However, the sample companies may have capital structures that are quite different both among themselves and compared to Dominion Virginia Power. Simply averaging the estimated costs of equity from the sample companies and recommending that average as the allowed return on equity for the Company does not consider any differences in financial risk. If these differences are not considered, the result could be a material error in the estimated cost of equity for Dominion Virginia Power.

[9] Oliver Testimony, p. 26.
[10] Preferred equity is ignored for simplicity, but the principles do not change with the addition of preferred stock to the capital structure.
[11] Gorman Testimony, p. 27.

Q.20 Is it appropriate to estimate the cost of equity for the sample companies using market data?

A20. Yes. Mr. Gorman, Mr. Oliver and I all estimate the cost of equity for the sample companies using market information. The alternative is to rely on accounting information on the return on equity realized on book value assets, as is done in the comparable earnings approach. The Discounted Cash Flow ("DCF") model and the risk positioning models (CAPM, ECAPM and risk premium method) rely upon market information, and the cost of equity estimates derived from those models reflect the business risk and financial risk of the sample companies at their *market value* capital structures. The returns on equity recommended by Mr. Gorman and Mr. Oliver are derived from these market based models, but then both treat these returns as if they were returns on book value equity.

Q21. How does the ATWACC approach address differences in financial risk?

A21. Most analysts choose sample companies that are expected to be of comparable business risk, but the sample companies may have capital structures that are quite different from each other as well as from the regulated company. As I discussed above, two otherwise identical companies with different (market value) capital structures would have different costs of equity (estimation errors aside) because of differences in financial risk. However their overall cost of capital, i.e., their ATWACCs, would be the same.

The ATWACC approach estimates the overall weighted-average cost of capital of the sample companies. The overall cost of capital estimate captures both the business risk and the financial risk of the company in a single number, i.e., the combined risk of the debt and the equity used to finance the assets. This, in turn, enables an "apples to apples"

comparison among the sample companies. This is why the ATWACC approach is the best way of approaching the cost of equity estimation problem – it is the only cost common to all companies of similar business risk and can therefore provide the only reliable anchor point.

Q.22 Mr. Gorman suggests that the ATWACC approach is "actually a market-to-book ratio adjustment in disguise" and that you were "attempting to repackage this and rename it 'risk positioning'" in your direct testimony.[12] Is this an accurate representation of the ATWACC approach?

A22. No. First, the risk positioning models (the CAPM, ECAPM and risk premium method) are cost of equity estimation models used by Mr. Gorman and Mr. Oliver, as well as in my direct testimony. In my direct testimony, I used the ATWACC method with the DCF model as well, so clearly it is not a "repackaged risk positioning model." Second, this statement reflects confusion regarding the ATWACC approach and represents a misunderstanding of basic financial principles.

Q23. Does the ATWACC methodology depend upon a market-to-book ratio in any way?

A23. No. The market-to-book ratio has no bearing whatsoever on this approach. The book value capital structure of the sample companies does not enter into the ATWACC calculations in any way, so it is impossible for the book value capital structure to have any impact on the ATWACC. Moreover, if the regulatory capital structure differs from the market value capital structure, an adjustment is still warranted even if the market-to-

[12] Gorman Testimony, p. 48.

book ratio were equal to 1.0, yet one could hardly claim that a market-to-book value "inflation" was being made in that scenario.[13]

Q24. Why should market values, as opposed to book values, be used when estimating the capital structure for use in financial risk adjustment?

A24. Market values reflect the actual risks that investors are facing. Consider an investor who purchases a share of stock for $20 in a company with a market-to-book value ratio of 2.0, which means that the book value of the purchased share is actually $10. Suppose also that the expected dividends on the share total $2 for the coming year. Does this mean that the investor is expecting a return of 20% (= $2/$10) that year? Clearly not. The investor put $20 into this investment and is receiving $2 this year – a rate of return of 10%. That is what would be reflected in the DCF and risk positioning estimates – dividend and price data. To match these costs of equity estimates to each company's book value capital structure misrepresents the true risk-return tradeoffs. The money at risk is not the book value of $10, but the market value of $20 dollars. As a simple example of this idea, consider a house purchased 10 years ago for $100,000. If the market value of the house declines from $400,000 to $300,000, you have suffered a loss of $100,000 even though the book value is still $100,000.

In fact, most investors don't even know the book value of the stocks they buy. They focus on the market value. All rates of return demanded by investors are based on market values, not book values. This is why determining the overall cost of capital must necessarily rely on market value capital structures – one of the most basic results from modern finance theory. The cost of equity estimated by both the DCF model and the risk

[13] *Id.*

positioning model reflects each sample company's level of business risk and its level of financial risk in terms of market values.

Q25. Please explain the apparent source of the misunderstanding of the ATWACC approach.

A25. The source of the confusion appears to be a misunderstanding that the ATWACC is a *rate of return*, not a dollar amount of return. The flaw in reasoning can be illustrated in the following simplified example. Suppose that the cost of equity estimated using the DCF or the risk positioning method is 10% for a regulated company with a market value capital structure with 66.6% equity and 33.3% debt. (See Step 1 in Figure 1 below.) Suppose that the book value capital structure of the regulated company is 50% equity and 50% debt and that the ATWACC adjusted return on equity is 12.1% for the regulatory capital structure. (See Step 2 in Figure 1 below.) Does this mean that if the Commission allows a 12.1% return on equity that the return on the market value of equity will be 12.1%? The answer, of course, is no. The reason is that the estimated return on equity is applied to the *book value* of equity in the rate base not the market value of equity. In this example, the market-to-book ratio is 2.0, the market return on equity would be about 6%, half of the allowed return on the equity financed portion of the rate base, which would likely be less than the company's current market cost of debt. (See Step 3 in Figure 1 below.)

Figure 1: Example of ATWACC approach, and the resulting return on the market value of equity.

Step 1: Compute ATWACC using market values

	Market Values		Return	Tax Rate	Wt. Average
Equity	1000	67%	10.0%		0.067
Debt	500	33%	6.0%	40%	0.012
	1500	100%		ATWACC	**0.079**

Step 2: Using book value capital structure, compute allowed return on equity that yields the ATWACC determined in Step 1

	Book Values		Return	Tax Rate	Wt. Average
Equity	500	50%	12.1%		0.061
Debt	500	50%	6.0%	40%	0.018
	1000	100%		ATWACC	**0.079**

Step 3: Implied allowed equity return on market value of equity

	Dollar amount	Rate of Return
Equity Return	60.7	**6.07%**

In the example, note that the overall after-tax cost of capital is constant at 7.9%, but the return on equity must be changed in order for the overall cost of capital to remain constant as the capital structure changes. In other words, the ATWACC approach is recommending a constant overall *rate of return* on assets regardless of the capital structure.

Q26. Please summarize the ATWACC approach you are recommending.

A26. I am recommending that the Commission recognize that financial risk is important and that it affects the cost of equity estimates from the models. The ATWACC approach captures both business risk and financial risk in one estimate of the market required rate of return for the sample companies. Applying that rate of return to the rate base gives a return consistent with the market determined cost of capital and the regulatory capital structure of the Company. If the regulatory capital structure has more debt as recommended by Mr. Gorman, then the return on equity must be higher in order to

maintain a constant ATWACC. If the regulatory capital structure has less debt, then the return on equity should be reduced. Note that if adopted, the ATWACC approach makes the debate about the appropriate capital structure much less contentious.

Q27. If the allowed return on equity is 12% instead of 10%, are you saying that this will or will not maintain the current market-to-book ratio?

A27. The ATWACC approach does not say anything about this. Instead, the ATWACC approach simply says that the estimated return on investments of comparable business risk to the regulated company is equal to the ATWACC. Therefore the regulated assets should be allowed a *rate of return* equal to the ATWACC on the *book value* rate base. Moreover, the dollar amount of equity return is unlikely to justify the market-to-book ratio of 2.0 in the above example. Because, as noted above, the market return on equity is about 6% which may well be less than the company's cost of debt.

Q28. But isn't a market-to-book ratio of 2.0 prima facie evidence that the allowed return on equity has been too high?

A28. No, but it does say that we don't have a complete theory of the determination of security prices. Professor Andrei Shleifer summarizes this point in his book, *Inefficient Markets An Introduction to Behavioral Finance*:

> Despite considerable progress, our knowledge of determination of security prices remains limited. Although we may reject the null hypothesis of market efficiency with more confidence than before, we still know relatively little about such key determinants of prices as expectations about fundamentals, discount rates, and simple movements of demand. Behavioral finance and the finance of the determination of valuations more generally, has many years to grow.

We simply don't have complete explanations of the level of stock prices in the market.

Q29. Is the ATWACC method compatible with the use of a book value rate base?

A29. Yes. The use of book value rate base is perfectly consistent with the use of a rate of return calculated from market data using the ATWACC method. The book value rate base is merely a historical record of the amount of assets purchased by investors to provide service to customers. All rate-of-return analysts estimate a market cost of capital to apply to that investment, as everyone in this proceeding did. The only difference is that I calculated the overall market rate of return on assets in my direct testimony and applied that overall rate of return to the rate base. Because the regulated capital structure differs from the market value capital structures of the sample companies, the allowed return on equity must be adjusted so that the weighted-average cost of capital used to set rates is equal to the market-determined overall cost of capital from the sample of companies with comparable business risk.

Q30. Are there other statements made by VCFUR witness Gorman that confuse the concept of financial risk, the ATWACC approach or your testimony on these matters?

A30. Yes. Mr. Gorman made the following statements, each of which is incorrect.[14]

> ...the underlying assumption of the adjustment is that there is more financial risk in book value capital structures than there is in a market value capital structure... [and similarly] ... there are not two financial risks faced by investors, one based on book value and a second based on market value.
>
> ...his [Dr. Vilbert's] adjustment does not consider the total investment risk of the enterprise but rather is focused only on the amount of financial risk differential between book and market values.

I will address each of these statements below.

[14] Gorman Testimony, pp. 47-48.

Q31. Please address Mr. Gorman's first statement that "the underlying assumption of the [ATWACC] adjustment is that there is more financial risk in book value capital structures than there is in a market value capital structure." Is there a difference in financial risk for a company based upon its market value and book value capital structures?

A31. No. I do not claim that there is more financial risk in the book value capital structure than in the market value capital. There is only one measure of a company's financial risk, and it is based upon the market value capital structure. Nothing in my direct testimony states or intends to state that there are two measures of financial risk. As noted, the ATWACC book values do not appear in the ATWACC calculation, so the basis of these statements is not apparent.

Q32. The Company is regulated on the basis of its book value rate base. How does the difference between the market value capital structures of the sample companies and the book value capital structure of the Company affect the recommended return on equity?

A32. This is the essence of the ATWACC approach, as discussed above. The issue addressed by the ATWACC approach is rate of return that should be allowed on the Company's rate base. The return on equity measured by the standard models is a function of business and financial risk. To apply the "rate of return" estimated in the market to the book value rate base for the regulated company requires that the rate of return be properly estimated. Applying the sample estimated cost of equity to the book value of equity does not consider the financial risk of the sample companies. The ATWACC approach combines the risk of the debt and equity used to finance the regulated assets and applies this overall

market-determined rate of return to the rate base. Capital structure affects the required return on equity, but not the ATWACC.

Q33. Please address the second statement that you did not consider "the total investment risk of the enterprise but rather that you focused only on the amount of financial risk differential between book and market values?"[15]

A33. The meaning of this statement is not clear. Mr. Gorman, Mr. Oliver and I were all attempting to estimate the cost of equity for the Company that, by definition, is not the total investment risk of the enterprise. On the other hand, I am the only one who actually measured the total investment risk of the enterprise by consideration of the overall cost of capital for the sample companies. This is precisely the difference between the approach in my direct testimony and the approach used by both Mr. Gorman and Mr. Oliver.

Q34. Do you have examples of Mr. Gorman's misapplication of the concept of financial risk?

A34. Yes, there are several. First, Mr. Gorman does not take the differences in financial risk between the sample companies and the regulatory capital structure for the Company into account. Second, Mr. Gorman recommends substituting a very large percentage of debt for equity in the Company's regulatory capital structure with no consideration of the corresponding increase in financial risk resulting from the recommendation. As a result, Mr. Gorman's recommendation of 10.2% is inconsistent with the sample evidence and the financial risk of Dominion Virginia Power.

[15] Gorman Testimony, p. 48.

Q35. Mr. Gorman claims that a 10.2% cost of equity is, in fact, consistent with the financial risk of Dominion Virginia Power. How do you respond?

A35. As noted above, Mr. Gorman makes this claim based upon the book value capital structures of the sample companies, but financial risk is a function of the market value capital structures of the sample companies. To argue, as Mr. Gorman does, that financial risk is measured by book value capital structures is incorrect, and it is inconsistent with financial theory and real world economics.

Q36. How do the market value capital structures of the sample companies compare to Dominion Virginia Power's regulatory capital structure?

A36. The average market-value equity ratios in the sample from my direct testimony are 62% for the DCF models, and 57% for the risk positioning models. As such, the sample companies are significantly less leveraged (i.e., have less financial risk) than the Company would be at the approximately 44% equity ratio proposed by Mr. Gorman. This additional financial risk demands additional return in the market.

Q37. If the Commission were to accept Mr. Gorman's recommendation to increase the percentage of debt in the regulatory capital structure, what would be the effect on the required return on equity?

A37. If the Commission were to determine that replacing equity with debt in the regulatory capital structure was warranted for Dominion Virginia Power, the cost of equity would have to be increased to recognize the additional financial risk this would impose on Dominion Virginia Power's remaining equity. Based on my estimates of the overall cost of capital for the sample, shifting 6.8 percentage points from equity to debt in the capital structure would result in a point estimate of the cost of equity above 12%. Table 1 below

displays the effect of the change in capital structure on the cost of equity estimates compared to Table 3 in my direct testimony. Note that only the regulatory capital structure is different. The sample's estimated ATWACC for each estimation method is the same as reported in Table 3 of my direct testimony. Comparison of the two tables shows that reducing the equity percentage in the capital structure increases the cost of equity by more than 1 percentage point because of the increased financial risk inherent in a more leveraged capital structure.

Table 1

Regulatory Capital Structure: 43.9% Equity / 6.1% Preferred / 50.0% Debt — *2008 Tax Rate: 38.8%*

C. Credit Ratings are not a Measure of Equity Risk

Q38. VCFUR witness Gorman also claims that a company's credit rating is a measure of the required return on the company's equity.[16] Is that correct?

A38. No. As Mr. Gorman acknowledges,[17] the cost of equity is a function of the company's systematic risk (i.e., its non-diversifiable risk), not total risk as measured by a company's

[16] Gorman Testimony, p. 17.

[17] Gorman Testimony, p. 42.

credit rating. Systematic risk, also called market risk, is the risk that investors cannot diversify away by holding a portfolio of investments. It is also the risk that affects a company's required return on equity and is measured by a company's beta not its credit rating. Bond holders care about total risk because they cannot diversify their risk exposure the same way equity holders can because bond holders have no upside. Bond investors usually get the promised payments of interest and principal, but they will not get more and may get less. In contrast, equity returns are sometimes greater or lower than expected.

Q39. Can you demonstrate that equity risk is different from credit risk?

A39. Yes, consider Table 2 below, which displays the credit ratings and estimated betas for a number of well-known companies. As can easily be seen, there is no direct relationship between a company's credit rating and its beta estimate. Companies with a high or low credit rating can have a high or a low beta; one is not a predictor or indicator of the other.

Table 2

Comparison of Credit Ratings and Equity Betas

S&P Ranking / Beta	AA	A	BBB	BB
1.50	Goldman Sachs Group (1.51)	Merrill Lynch & Co (1.49)	Raymond James Financial (1.50)	Rock-Tenn Co (1.50)
1.25	Citigroup, Inc. (1.25)	Carnival Corp (1.25)	National Oilwell Varco, Inc. (1.25)	Central Vermont Public Service Corp (1.26)
1.00	Northwest Natural Gas Co (1.02)	Bristol-Myers Squibb Co (1.00)	Goodrich Corp (1.00)	Avista Corp (0.99)
0.75	Merck & Co, Inc. (0.79)	Consolidated Edison, Inc. (0.75)	Energy East Corp (0.75)	TNS, Inc. (0.75)
0.50	Procter & Gamble Co (0.57)	PepsiCo, Inc. (0.57)	Coventry Health Care, Inc. (0.56)	Harrah's Entertainment, Inc. (0.56)

Sources and Notes:
Data were retrieved from Bloomberg as of November 30, 2007.
The companies in this table are actively traded on New York Stock Exchange.
Credit Ranking is based on S&P Long-Term Local Currency Issuer Credit Rating.
Betas are adjusted and derived from the past two years of weekly return data.

Q40. What about companies in the same industry with different credit ratings? Would you agree then that a higher credit rating reflects lower equity risk?

A40. No. In general, the reverse is likely to be true.

Q41. Please explain how it could be that a higher (less risky) credit rating would indicate greater risk for the company's equity.

A41. Consider two otherwise identical companies, both of which have an investment grade credit rating, so neither is in financial distress. All else being equal, a higher credit rating for one is likely to be due to the use of less debt in the company's capital structure. Because the risk of the underlying assets is unchanged by the choice of financing, the higher credit rating leads to a lower cost of debt that, in turn, means that the company's equity must be riskier. This can be illustrated by reference to equation **(1)** from my direct testimony, which calculates the ATWACC:[18]

$$ATWACC = r_D \times (1 - T_C) \times D + r_E \times E \qquad (1)$$

where r_D = market cost of debt,
r_E = market cost of equity,
T_C = corporate marginal income tax rate,
D = percentage of debt in the capital structure, and
E = percentage of equity in capital structure.

The constant risk of the assets means that the ATWACC is constant as the capital structure changes. The higher market cost of debt resulting from a lower credit rating means that the cost of equity consistent with overall cost of capital estimate (i.e., the ATWACC) must be lower than for the identical company with a higher credit rating (i.e., one with a lower cost of debt).

[18] Note that this equation assumes that only debt and equity are in the capital structure, but one can add preferred equity to the equation if appropriate.

Q42. What is the implication of this section?

A42. Credit risk and equity risk are simply not the same, and it is a mistake to treat them as if they were as Mr. Gorman has done. Observing that the average credit ratings for companies in the electric utility industry have improved recently provides no evidence that the risk of the equity of the companies in the industry has been reduced. Credit ratings are derived from the total risk of the enterprise, whereas market risk (i.e., systematic risk) is based upon the relationship between the company's return on equity and return on the market. Risks that can be diversified away reduce credit risk but have no effect on the required return on equity. Recall that beta is a measure of systematic risk, the risk that matters for the cost of capital. The conclusion is that the risk of equity of companies with a low credit rating is not necessarily more risky than that of a company with a higher credit rating.

III. MR. GORMAN MISINTERPRETS HIS OWN RESULTS

Q43. Do you believe that Mr. Gorman's methodology to estimate the sample companies' costs of equity is materially flawed?

A43. No, but Mr. Gorman's interpretation of his results is materially flawed. Although I applied a somewhat different sample selection procedure in my direct testimony to ensure reliable estimates, Mr. Gorman's implementation of the DCF and risk positioning models for the individual sample companies is generally similar to that in my direct testimony with one major exception. My primary concern, however, is how Mr. Gorman's results are interpreted, both in terms of adjusting for differences in financial risk and in terms of the weight that Mr. Gorman appears to place on his multi-stage DCF results.

Q44. What is the major exception you mentioned?

A44. Mr. Gorman's Schedule 12 displays the average beta estimates for the sample companies over the last five years as reported by *Value Line*. Recall that beta is a measure of the company's market risk (i.e., its systematic risk), the risk that affects a company's cost of equity. *Value Line* estimates beta based upon 260 weeks (5 years) of historical return data, and the betas estimated by *Value Line* have been steadily increasing over the period 2003 to 2006, as displayed in Schedule 12. The current average beta for Mr. Gorman's sample is 1.07, but Mr. Gorman uses a beta of 0.82 in his risk positioning (CAPM) estimates. Had Mr. Gorman used the most recent average beta estimate in the model, the cost of equity estimate for the sample would have been about 160 basis points higher (i.e., (1.07 – 0.82) * 6.5%) = 12.1%). It would have been about 50 basis points higher if the current median estimate of 0.90 had been used (i.e., (0.90 – 0.82) * 6.5%) = 11.0%). In other words, Mr. Gorman's CAPM return estimate for the sample would be 12.1% (or 11.0% using the median beta estimate) instead of his reported estimate of 10.5%.[19]

Q45. Why is it incorrect to average the betas over the last five years?

A45. There are a number of reasons, but primarily it is because the *Value Line* beta estimates are already based on 5 years of data. Using betas estimated in 2003 results in the use of data from as long ago as 1998. Much has changed in the electric industry since 1998.

Q46. Mr. Gorman claims that the higher betas do not reflect the risk of the companies going forward.[20] How do you respond?

[19] Gorman Testimony, Schedule 14.

[20] Gorman Testimony, p. 34.

A46. Many of the things that Mr. Gorman references as reducing risk are likely to be diversifiable risks, which are risks that affect total risk but not systematic risk, the risk that affects the cost of equity. This observation is confirmed by the fact that the average credit rating of companies in the electric utility industry is improving. In addition, much of the improvement in average credit ratings comes from a return to investment grade of companies that lost their investment grade in 2002-2003, whereas only a few companies have been moved from, for example, a BBB-rating to an A-rating. On the other hand, changes in the industry referenced in my direct testimony[21] are likely to have increased the risk of the sample companies compared to a few years ago, which is also confirmed by the increase in the average betas of the sample companies. It is highly likely that betas measured over the last 5 years fully capture any changes in risk either an increase or a decrease, so that using data from as long ago as 1998 is unnecessary and likely to bias the results.

Q47. You have already described your concerns with the financial risk adjustment process. Please explain your concerns with the emphasis Mr. Gorman placed on his DCF estimates.

A47. Mr. Gorman's results are summarized in Table 1 of his filed testimony and are reproduced below in Table 3.[22] The left hand side of Table 3 illustrates Mr. Gorman's results as reported, and the right hand side illustrates the correct values from Mr. Gorman's schedules. Only the CAPM estimates reflect a change in assumption. The other changes are simply corrections to the results reported in the schedules. Note that of

[21] Testimony of Michael J. Vilbert, on behalf of Virginia Electric and Power Company, filed on July 13, 2007, ("Vilbert Direct"), p. 27.

[22] Gorman Testimony, p. 36.

the four methods reported, only the two-stage DCF estimates are less than 10.2%, yet Mr. Gorman recommends a rate of return on equity of 10%.

Q48. How did Mr. Gorman arrive at his cost of equity recommendation?

A48. According to the Gorman Testimony, Mr. Gorman takes "the midpoint of my [his] estimated return on equity range for VEPCo of 9.4% to 10.6%".[23] Ignoring the fact that the range is misstated and should be 9.5% to 10.7% based upon the corrected results from Mr. Gorman's Table 1, taking the midpoint effectively gives the low outlier range of 9.4%-9.6% (corrected it should be 9.5% to 9.6%) for the two-stage DCF model greater weight than any of its peers. For example, an average estimate of the four methods would be about 10.3%, and the median would be 10.4%. Mr. Gorman must have greater confidence in the two-stage DCF methodology than any other method he employs to arrive at the recommendation in this way.

Table 3

[23] Gorman Testimony, p. 36.

Q49. Why is the heavy reliance on the multi-stage DCF model a concern?

A49. As noted in my direct testimony,[24] there are a number of issues that make the reliability of DCF model questionable at this time for the electric utility industry. Mr. Gorman echoes some of these concerns on pages 23-25 of his testimony. Moreover, Mr. Gorman correctly recognizes that abnormal growth rates can greatly reduce the reliability of the constant growth DCF methodology.[25] However, my concern arises from Mr. Gorman's failure to recognize that this problem with growth rates also raises concern over the reliability of his two-stage DCF model as well. The results of the DCF model depend critically on the forecasts of dividend growth rates, but cost of capital analysts generally have no information on forecast growth rates of earnings or dividends for periods longer than five years. All analysts are forced to assume a pattern of dividend growth for years six through infinity for the model, but those assumptions determine the results. Since investor expectations drive current prices used in the DCF formula, errors forecasting growth rates at this horizon will typically translate into material errors estimating the cost of equity. Investor expectations for growth beyond year five are likely to be very diverse when there are abnormal growth rate forecasts in the short run, as well as when there is great uncertainty as to the long-term path of the industry as there is today.

As a consequence, the DCF model is unreliable unless it is being applied to an industry that is in a stable growth path for the foreseeable future. Mr. Gorman applies an estimate of the growth in domestic product ("GDP") in year six to infinity for each of his sample companies. Unless investors believe that the industry's uncertainty and growth will

[24] Vilbert Direct, p. 3.

[25] Gorman Testimony, pp. 21-22.

dissipate by that time, DCF estimates will be biased. There is enough evidence to doubt, however, that the regulated electric utility industry can be currently characterized as stable – and similar doubts apply to its future outlook as well. As a result, the DCF methodology is not reliable at this time in any form for the electric utility industry.

Q50. Why do you believe that the industry is not likely to be stable six years from now?

A50. There are several reasons why uncertainty about the industry's future is not likely to have decreased as Mr. Gorman implicitly assumes. First, echoing Mr. Gorman's statements, a September 28, 2007 *Value Line* report points to the need for substantial investment in generation and transmission.[26] This point is repeated in several reports commissioned by the *Edison Electric Institute.*[27,28] The Virginia Energy Plan also calls for significant expenditure on transmission and other infrastructure.[29] The prices of fossil fuels have increased dramatically over the last few years. Construction prices have also recently increased rapidly, and uncertainties exist about how the rise in prices will affect the infrastructure investment strategy:

> However, rising construction costs will put additional upward pressure on retail rates over time, and may alter the pace and composition of investments going forward. The overall impact on the industry and on customers, however, will be borne out in various ways, depending on how utilities, markets and regulators respond to these cost increases.[30]

---

[29] The Virginia Energy Plan, Chapter 4.

[30] *Ibid,* p. 31.

Second, public concern with environmental sustainability and the need for renewable sources of energy has led to the adoption in many states of renewable generation requirements. It seems certain that environmental concerns will increase in the future, but the impact of these concerns on renewable energy requirements and restrictions on greenhouse gases is uncertain. This uncertainty is a clear source of risk for electric utility investors. For example, at the federal level, the House passed a bill this summer proposing a 15% renewable energy requirement by 2020, while an earlier Senate bill on energy did not include a similar requirement.[31,32] Clearly, environmental issues are an important source of uncertainty about future costs and regulation, and increase the risk of regulated electric utilities. The sheer magnitude of the infrastructure need and the complexities involved make it highly doubtful that the outlook five years from now will be significantly different from what it is today.

Q51. Please summarize your conclusions regarding the stability of the electric utility industry at this time.

A51. The future structure of the electric utility industry is far from certain. The industry faces the need for substantial capital investment going forward to meet the challenges of new environmental and safety standards as well as the need for conservation. Acquiring the capital necessary for the required investments will require a supportive regulatory environment including an adequate return on equity. These challenges and the resulting uncertainty mean that the industry will not be the stable, low risk environment envisioned

[31] These pieces of legislation have been widely reported in the national press. For a specific reference, see *Edison Electric Institute* press release of August 4, 2007, available at http://www.eei.org/newsroom/press_releases/070804.htm.

[32] The Virginia Energy Plan calls for 7 percent renewable energy by 2012 and 12 percent by 2022.

by Mr. Gorman, but that stability is precisely the condition required for the reliable estimation of cost of equity using the DCF model.

Q52. Please summarize your conclusions from this section of your rebuttal.

A52. Only by relying heavily on the results of the multi-stage DCF model is Mr. Gorman able to arrive at a recommendation as low as 10% based on the results from his own models, but as noted above, the necessary conditions for the reliable implementation of the DCF model do not exist at this time. Moreover, the CAPM results are understated because Mr. Gorman arbitrarily uses a five-year average of *Value Line* estimated betas which are themselves based on five years of data. Had Mr. Gorman relied on the most recent *Value Line* betas, the mid-point of the range of estimates would have been at least 50 basis points higher, even given the unwarranted weight that Mr. Gorman gives the multi-stage DCF model.

IV. THE ECAPM APPROACH

Q53. Mr. Gorman claims that the CAPM estimates in your direct testimony are flawed. In particular he claims that using *Value Line's* adjusted betas with the ECAPM alpha adjustment "double counts the increase in the CAPM return estimate for companies with betas lower than 1."[33] Is this correct?

A53. No. Contrary to Mr. Gorman's opinion, *Value Line's* adjustment of raw betas is not "to accomplish the same thing"[34] as adjusting the security market line to conform to the evidence cited in my direct testimony. *Value Line's* adjustment is a standard industry practice meant to reflect the tendency of betas to regress toward a mean of one. In the

[33] Gorman Testimony, p. 46.

[34] *Id.*

presence of regression toward the mean, estimating beta based on past returns yields a biased estimate of the true beta. This point was first raised by Professor Marshall Blume in 1971,[35] and it has been widely acknowledged since. The important point to remember is that the *Value Line* adjustment is applied to the *estimated* beta, not the true beta. If the true company betas were known, the adjustment would not be necessary. The need to adjust beta is a different concept, however, from a having a *true* security market line that is flatter than that predicted by the CAPM. (See Figure 1 in the Vilbert Direct.)

Q54. But didn't you respond that you knew of no studies using *Value Line* beta estimates in the studies you referenced with regard to the ECAPM?

A54. Yes, I also noted that researchers typically calculate their own betas rather than rely on estimates from *Value Line;* however, the issue is not who publishes the betas but whether adjusted betas are an explanation of the higher intercept and shallower slope of the ECAPM. Mr. Gorman appears to misinterpret the cited literature. Indeed, the paper by Litzenberger, R., K. Ramaswamy, and H. Sosin (1980), cited in both my direct testimony and my data responses explicitly considers the alpha parameter using both adjusted and "individually" adjusted betas. While it is true that the academic articles did not rely upon betas published by *Value Line*, the use of adjusted betas was considered and not determined to be the explanation addressed by the ECAPM. Indeed, most of the studies documenting the under estimation of the required return from the CAPM were published after the 1971 Blume study, so if mean-reversion in the beta had been the explanation, it is likely the researchers would have reached that conclusion, but clearly they did not. Furthermore, I use values of "alpha" that are conservative relative to existing estimates. Therefore, even if the beta adjustment were to "flatten" the security market line more

[35] Blume, Marshall E. (1971), "On the Assessment of Risk," *Journal of Finance*, 26(1), pp. 785-795.

than necessary to account for the bias in the estimate (which cannot be known with certainty), it is very unlikely that the combined effect of the two adjustments would result in overestimating the Company's return on equity.

Q55. Mr. Gorman asserts that "using the Treasury bond yield as a proxy for the risk-free rate in the CAPM analysis can produce an overstated estimate of the CAPM return." Do you agree?

A55. Not if the market risk premium ("MRP") is matched with the proxy for the risk free rate. This is why I use a MRP of 6.5% (as did Mr. Gorman) when using a long-term ("LT") Treasury bond yield in the CAPM and a MRP of 8.0% when using a Treasury bill yield. The 1.5 difference in MRP is equal to the average difference in the yields on Treasury bills compared to Treasury bonds.[36] In a footnote, Mr. Oliver references Mr. Gorman's testimony on this point but seems to make no judgment on the accuracy of the statement. Finally, as shown in table MJV-C1 in Appendix C of my direct testimony, the size of the correction needed for the CAPM is greater than the 1.5% maturity premium used to adjust the MRP when using the LT Treasury bond yield.

Q56. Mr. Oliver also questions your use of the ECAPM, claiming that the ECAPM does "nothing more than inflate [Dr. Vilbert's] cost of equity estimate."[37] How do you respond?

A56. In a manner similar to the objection to my use of the ATWACC approach, Mr. Oliver does not challenge the empirical evidence underlying the use of the ECAPM. Instead, he simply charges that the ECAPM results in a higher estimated cost of equity for the

[36] See Workpaper #1, Panel B, Table No. MJV-9, in my direct testimony, for the calculation of the 1.5% maturity premium.

[37] Oliver Testimony, p. 29.

sample companies. The ECAPM provides higher estimates of the cost of equity for stocks with betas less than 1.0 and lower estimates for the cost of equity for stocks with betas greater than 1.0. But the critical point is the ECAPM is consistent with the empirical evidence from repeated tests of the CAPM over many years, as documented extensively in my direct testimony, Appendix C. I attempted to estimate the cost of equity as accurately as possible, and it is wrong to ignore evidence of a bias in the model particularly when correcting the bias is so straightforward. Moreover, as shown in Appendix C, Table No. MJV C-1, the correction applied in my direct testimony is lower than would be justified by the empirical evidence.

Q57. Mr. Oliver also criticizes your use of forecasted U.S. government interest rates in the risk positioning models, claiming that interest rates have declined since the time that your direct testimony was filed.[38] How do you respond?

A57. This seems to be a misunderstanding. In my direct testimony, I used the actual (not forecast) U.S. government bond yield curve based upon a 15-day period ending June 11, 2007, a time period corresponding to the preparation of my direct testimony. The long-term bond yields I used were the actual yields at the time. I also estimated the short-term interest rates inherent in the yield curve from the data at the time, but these are not forecast interest rates. At the time short-term interest rates were actually higher at the time than the 4.1% used in my testimony. Had actual short-term rates been used, the value would have been about 4.85%.

[38] Oliver Testimony, p. 27.

Q58. The Fed reduced interest rates again on December 11, 2007. Does this suggest that your cost of equity estimates should also be reduced?

A58. Not necessarily. It is true that interest rates have declined recently as fears of a recession resulting from the sub-prime mortgage defaults have increased, but inflation fears are also increasing with high energy costs, high budget deficits, high trade deficits and a weakened U.S. dollar. As a result, the path of interest rates going forward is uncertain because the Fed may be forced to increase interest rates to control inflation or may reduce interest further to prevent a recession.[39]

Q59. Do you have any other comments on the cost of equity estimation methods employed by Mr. Oliver?

A59. Yes. I will briefly address his DCF estimates and his risk premium approach.

Q60. What are your comments on Mr. Oliver's DCF estimates?

A60. I have already discussed my concerns with the reliability of the DCF method at this time for an industry lacking the stable conditions necessary for reliable application. I also have a concern with the growth rate estimate used in his DCF. Mr. Oliver's Schedule 9 displays the growth rate estimates he used in the model. As can be seen in the Schedule, the growth rate estimates vary widely from company to company and for the same company. Moreover, the method by which he determines the range of growth rate estimates for the model is not clear. It seems he simply selected the values to use from the range of observed estimates. All of this calls into question the reliability of the estimates.

[39] See the Economist.com, "From Santa to Scrooge," December 12, 2007.

Q61. What are your comments on Mr. Oliver's risk premium estimates?

A61. I believe that Mr. Oliver has made a fundamental error regarding the Ibbotson and Chen estimate of 9.76% displayed in his Schedule 15.

Q62. What is the fundamental error?

A62. First, the estimate of 9.76% is for the stock market as a whole, not an individual stock.[40] Second, the estimate is a geometric average return, not the arithmetic average return, which is a mistake when estimating the required return. The arithmetic average for the market is 11.18% based upon a market risk premium of 6.35%.[41]

Q63. Is it appropriate to use the geometric mean to estimate the expected return from the risk positioning model?

A63. No. While the geometric mean return is appropriate for consideration of achieved returns over a period of time, it is well established that the geometric mean is not correct for estimating the expected return, especially in a regulatory setting. This is well understood in the broader finance community. For example, Ibbotson Associates state,

> The equity risk premium data presented in this book are arithmetic average risk premia as opposed to geometric average risk premia. The arithmetic average equity risk premium can be demonstrated to be most appropriate when discounting future cash flows. For use as the expected equity risk premium in either the CAPM or the building block approach, the arithmetic mean or the simple difference of the arithmetic means of stock market returns and riskless rates is the relevant number. This is because both the CAPM and the building block approach are additive models, in which the cost of capital is the sum of its parts. The geometric average is more appropriate for the reporting past performance, since it represents the compound average return.[42]

---

[40] This estimate is displayed in the *Morningstar 2007 Yearbook, Valuation Edition*, p. 96.

[41] *Morningstar, 2007 Yearbook, Valuation Edition*, p. 97.

[42] Ibbotson Associates, *Stock, Bonds, Bills and Inflation, Valuation Edition*, 2007 Yearbook, p. 77.

Similarly, the *New Regulatory Finance* text by Roger A. Morin (2006) argues,

> Only arithmetic means are correct for forecasting purposes and for estimating the cost of capital. There is no theoretical or empirical justification for the use of geometric mean rates of returns as a measure of the appropriate discount rate in computing the cost of capital or in computing present values. There is no dispute in academic circles as to whether the arithmetic or geometric average should be used for purposes of computing the cost of capital.[43]

Finally, the text by Bodie, Kane, and Marcus (2005) states,

> [I]f our focus is on future performance, then the arithmetic average is the statistic of interest because it is an unbiased estimate of the portfolio's expected return (assuming, of course, that the expected return does not change over time). In contrast, because the geometric return over a sample period is always less than the arithmetic mean, it constitutes a downward-biased estimator of the stock's expected return in any future year.[44]

Based on academic and other literature, the geometric average based MRP is not appropriate for estimating cost of capital in a regulatory setting.

Q64. Please summarize your comments on Mr. Oliver's estimation methods.

A64. In my opinion, the conditions necessary to implement the DCF model reliably are not present. Mr. Oliver's risk premium estimates appear to be geometric average returns for the market as a whole, which is inappropriate to estimate required returns for a regulated company. Moreover, it is not clear what the direct relevance of the geometric average return on the entire market may be to setting the allowed return for the Company.

V. CONCLUSIONS

Q65. Please summarize your comments on Mr. Gorman's and Mr. Oliver's estimates of recommended allowed return on equity for Dominion Virginia Power.

A65. Neither testimony recognizes financial risk because both simply apply the cost of equity estimated from the models directly to the Company. To arrive at his 10% estimate, Mr. Gorman inappropriately gives a disproportionately greater weight to the two-stage DCF results than he gives his other estimates. This action is highly debatable. Moreover, some of the estimates reported in his Table 1 are incorrect, including his reliance on betas that are the average of those estimated over a nine year period instead of the most recent beta estimates. Even without considering financial risk, Mr. Gorman's estimates are more consistent with a recommendation of 10¾% than 10%.

Mr. Oliver's recommendation of 10% is similarly flawed. His implementation of the DCF model is highly subjective because of his estimation of the growth rates in the model. Moreover, the conditions for the reliable implementation of the DCF model do not exist at this time for this industry. The relevance of his risk premium estimates is also questionable in that they are geometric average estimates for the market as whole. Neither geometric average estimates nor estimates of the return on the market are directly relevant for estimating the allowed return for the Company.

Q66. Does this conclude your testimony?

A66. Yes, it does.

TABLES AND WORKPAPERS

I. INTRODUCTION AND SUMMARY

Q1. Please state your name and address for the record.

A1. My name is Michael J. Vilbert. My business address is The Brattle Group, 44 Brattle Street, Cambridge, MA 02138, USA.

Q2. Please describe your job and your educational experience.

A2. I am a Principal of The Brattle Group, ("Brattle"), an economic, environmental and management consulting firm with offices in Cambridge, Washington, London, San Francisco and Brussels. My work concentrates on financial and regulatory economics. I hold a B.S. from the U.S. Air Force Academy and a Ph.D. in finance from the Wharton School of Business at the University of Pennsylvania.

Q3. What is the purpose of your testimony in this proceeding?

A3. I have been asked by Dominion East Ohio (the "Company" or "DEO") to estimate the cost of equity that the Public Utilities Commission of Ohio (the "PUCO" or the "Commission") should allow DEO an opportunity to earn on the equity financed portion of its rate base.

To accomplish this task, I estimate the overall cost of capital for a sample of regulated natural gas local distribution companies ("gas LDCs") using the discounted cash flow ("DCF") and the risk positioning models. I then evaluate the relative risk of DEO compared to the sample companies to determine the recommended cost of equity for a regulatory capital structure with 44.8 percent equity, 0.8 percent preferred, and 54.3 percent debt, which is the Company's proposed capital structure in this proceeding based on its parent company's, Dominion Resources, Incorporated's, consolidated capital structure as of March 31, 2007.

Q4. Please summarize the parts of your background and experience that are particularly relevant to your testimony on these matters.

A4. Brattle's specialties include financial economics, regulatory economics, and the gas and electric industries. I have worked in the areas of cost of capital, investment risk and

related matters for many industries, regulated and unregulated alike, in many forums. I have testified or filed cost of capital testimony before the Federal Energy Regulatory Commission, the Arizona Corporation Commission, the Pennsylvania Public Utility Commission, the Public Service Commission of West Virginia, the Tennessee Regulatory Authority, the Public Service Commission of Wisconsin, the South Dakota Utilities Board, the California Public Utilities Board, the Canadian National Energy Board, Alberta Energy and Utilities Board, the Ontario Energy Board, and the Labrador & Newfoundland Board of Commissioners of Public Utilities. I have not previously testified before this Commission, but I submitted testimony on behalf of FirstEnergy's Ohio electric distribution companies in June 2007. Appendix A contains more information on my professional qualifications.

Q5. Please summarize how you approached this task.

A5. I review the evidence from a sample of regulated gas LDC's which were selected to be of comparable business risk to the Company's gas distribution operations in Ohio. My analyses consider cost of capital evidence from the risk positioning and discounted cash flow models, but I rely primarily on the risk positioning results because I do not believe that the DCF method is completely reliable at this time.

Specifically, I estimate the cost of equity for companies in the sample group using both cost-of-equity estimation methods. For each cost-of-equity estimate, I combine the cost of equity estimate with the sample company's market costs of debt and preferred stock to calculate each firm's overall cost of capital, i.e. its after-tax weighted-average cost of capital ("ATWACC"), using each company's market value capital structure as the weights. For each method of estimating the return on equity, I report the sample average ATWACC and the estimated cost of equity for this line of business at a capital structure with 44.8 percent equity. I thus present the cost of equity that is consistent with both the sample's market information and the Company's regulatory capital structure. (By

"regulatory capital structure," I mean the capital structure that DEO utilizes in its application.[1])

The use of the overall cost of capital automatically avoids problems that can arise when an analyst focuses separately on the individual components of the overall cost of capital (i.e., the cost of equity and the appropriate capital structure). The danger with that approach is that the estimated cost of equity from the sample may correspond to a very different level of financial risk than would exist at the regulated company's capital structure. The result could be an inconsistency between the allowed return on equity and the financial risk inherent in the regulatory capital structure.

Q6. What is your conclusion on the market-determined cost of capital for DEO based upon the results from the sample of regulated companies you selected?

A6. The best point estimate of the cost of equity for DEO is 12 percent for a capital structure with 44.8 percent equity, 0.8 percent preferred, and 54.3 percent debt, but it is more correct to say that the sample results indicate a range for the cost of equity estimates from 11½ to 12½ percent. The corresponding midpoint of the range of the overall cost of capital estimates, i.e., the ATWACC, for the benchmark sample companies is 7¾ percent with a range of 7½ to 8 percent. Note, that I specify a plus or minus ½ percent range for the return on equity and specify the point estimate to the nearest ¼ percent because I do not believe that it is possible to estimate the cost of equity more precisely than that.

Q7. What are the results for the DCF model?

A7. Results from the simple DCF model and for the multistage model are set out in the accompanying tables. (See Table No. MJV-6, Panel A - simple DCF and Panel B - multistage DCF.) After properly adjusting for the financial risk in the Company's regulatory capital structure, the sample average for the simple DCF model is 10.3 percent and for the multistage DCF model is 10.7 percent (See Table No. MJV-8). The results

[1] The capital structure that I customarily use in these analyses is based upon the long-term sources of capital, i.e., long-term debt, preferred equity and common equity. I do not use short-term debt because long-term assets are not generally financed with short-term debt.

for a sub-sample of companies with fewer data issues are 9.9 percent and 10.6 percent respectively.

Q8. Why do you believe that the DCF model is less reliable for this industry at this time than the risk positioning model?

A8. Results for the DCF model depend critically on the estimate of the dividend growth rate. A one percentage point error in the estimate of the growth rate results in a greater than one percentage point error in the cost of equity estimates. Natural gas prices have increased substantially and have become much more volatile recently compared to just a few years ago, which has affected the demand for natural gas. Although all of the companies in the sample have fuel cost adjustment clauses, the increased volatility of gas prices has increased the uncertainty of the industry's earnings going forward because full cost recovery on a timely basis is not guaranteed. The electric industry is a major source of demand for natural gas and it, too, is undergoing a period of uncertainty surrounding the ultimate structure of the industry. In addition, the potential imposition of additional environmental and safety restrictions on both the natural gas industry and the electric industry increases the uncertainty about future growth in earnings. For example, implementation of distribution integrity management rules to be introduced within the next year will inevitably lead to substantial capital and O&M expenditures among gas LDCs nationwide.[2] Uncertainty regarding the timely recovery of and return on these expenditures is likely to affect analysts' earnings forecasts. There have also been a number of mergers and acquisitions in the industry which may have the effect of increasing the market prices of the companies in the industry even if they are not the immediate target of a takeover which thereby reduces the dividend yield. These facts are not a description of an industry that could be characterized as stable with earnings and

[2] See "Distribution Integrity Management Program – Rulemaking is Under Way," *American Gas*, July 2007, pp. 12-16. However, according the American Public Gas Association's website, "APGA has learned that the proposed Distribution Integrity Management Program (DIMP) rule will not be issued until sometime this Fall due to concerns about the cost-benefit analysis. This means that the final rule will likely not take effect until sometime in 2008. This provides operators with additional time to prepare for this major rulemaking. APGA, through the Security and Integrity Foundation (SIF), is developing a model DIMP plan to assist public gas systems to develop written DIMP programs. The model plan will be available when the final rule is issued sometime next year."

dividends likely to grow at a constant rate over the foreseeable future, but that is precisely the condition necessary for the reliable implementation of the DCF model.

Although the DCF model results are less reliable than those based upon the risk positioning model at this time, I provide results using the DCF method, because it is a method that has been relied upon by commissions frequently in the past. In addition, results from the DCF model serve as a check on the results from the equity risk positioning approach.

Q9. What are the results for the risk positioning model?

A9. The sample average risk positioning results, again adjusted for differences in financial risk, range from 12.7 to 13.0 percent for the full sample, when using the long-term risk-free rate, and 12.4 to 12.7 percent for the sub-sample. I also report results for the risk positioning model using the short-term risk-free rate which are about 30-70 basis points ("bps") higher than for the long-term version of the model, but I place very little weight on those estimates in this proceeding because short-term interest rates have been quite variable lately. (See Table No. MJV-12 or Table 3 on page 35 below.)

Q10. You mentioned the importance of considering financial risk when evaluating the results of the models. Please explain how you adjust for financial risk.

A10. Both the DCF and the risk positioning models rely on market data to estimate the cost of equity for the sample companies. Those cost of equity estimates capture both the business risk and the financial risk of the sample companies' stocks. Business risk is the risk that the company would have if it were financed entirely with equity. Financial risk is the additional risk carried by the equity holders when debt is used to finance some of the assets. The more debt that is used by a company, the riskier the company's equity becomes. As explained in more detail below, the procedures I use consider both the business risk and the financial risk of the sample companies in comparison to DEO in determining my recommended cost of equity.

Q11. How is your testimony organized?

A11. *Section II* formally defines the cost of capital and touches on the principles relating to the cost of capital and capital structure for a business. *Section III* presents the methods used to estimate the cost of capital for the benchmark sample and the associated numerical analyses, and explains the basis of my conclusions for the benchmark sample's returns on equity and overall costs of capital. *Section IV* presents the results of these methods applied to the benchmark sample group, and presents the costs of equity implied by the results. My conclusions on the cost of equity for the Company are presented in *Section V*. Appendix B provides additional details on the selection of the sample and the calculation of the market value capital structures of the sample companies. Appendices C and D support *Sections III and IV* with additional details on the risk positioning model and DCF approach, respectively, including the details of the numerical analyses. Appendix E discusses the effect of debt on the cost of equity in more detail.

II. COST OF CAPITAL THEORY

A. THE COST OF CAPITAL AND RISK

Q12. Please formally define the "Cost of Capital."

A12. The cost of capital can be defined as *the expected rate of return in capital markets on alternative investments of equivalent risk*. In other words, it is the rate of return investors require based on the risk-return alternatives available in competitive capital markets. The cost of capital is a type of opportunity cost: it represents the rate of return that investors could expect to earn elsewhere without bearing more risk. "Expected" is used in the statistical sense: the mean of the distribution of possible outcomes. The terms "expect" and "expected" in this testimony, as in the definition of the cost of capital itself, refer to the probability-weighted average over all possible outcomes.

The definition of the cost of capital recognizes a tradeoff between risk and return that is known as the "security market risk-return line," or "security market line" for short. This line is depicted in Figure 1. The higher the risk, the higher is the cost of capital. A version of Figure 1 applies for all investments. However, for different types of securities,

the location (i.e., the intercept and the slope) of the line may depend on corporate and personal tax rates.

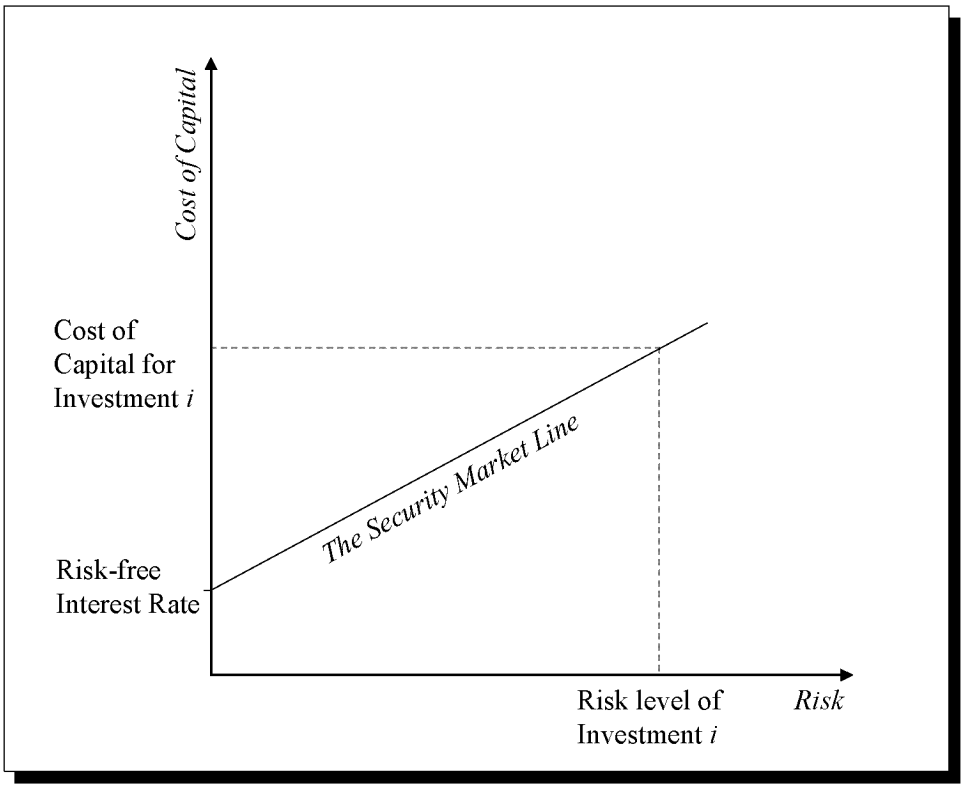

Figure 1: The Security Market Line

Q13. Why is the cost of capital relevant in rate regulation?

A13. It has become routine in U.S. rate regulation to accept the "cost of capital" as the right expected rate of return on utility investment.[3] That practice is normally viewed as consistent with the U.S. Supreme Court's opinions in *Bluefield Waterworks & Improvement Co. v. Public Service Commission*, 262 U.S. 678 (1923), and *Federal Power Commission v. Hope Natural Gas*, 320 U.S. 591 (1944).

From an economic perspective, rate levels that give investors a fair opportunity to earn the cost of capital are the lowest levels that compensate investors for the risks they bear. Over the long run, an expected return above the cost of capital makes customers overpay

[3] A formal link between the cost of capital as defined by financial economics and the right expected rate of return for utilities is established by Stewart C. Myers, "Application of Finance Theory to Public Utility Rate Cases," *The Bell Journal of Economics and Management Science*, 3:58-97 (Spring 1972).

for service. Regulatory commissions normally try to prevent such outcomes, unless there are offsetting benefits (e.g., from incentive regulation that reduces future costs). At the same time, an expected return below the cost of capital does a disservice not just to investors but, importantly, to customers as well. In the long run, such a return denies the company the ability to attract capital, to maintain its financial integrity, and to expect a return commensurate with that of other enterprises attended by corresponding risks and uncertainties.

More important for customers, however, are the economic issues an inadequate return raises for them. In the short run, deviations of the expected rate of return on the rate base from the cost of capital may seemingly create a "zero-sum game"-- investors gain if customers are overcharged, and customers gain if investors are shortchanged. But in fact in the short run, such action may adversely affect the utility's ability to provide stable and favorable rates because some potential efficiency investments may be delayed or because the company is forced to file more frequent rate cases. In the long run, inadequate returns are likely to cost customers – and society generally – far more than is gained in the short run. Inadequate returns lead to inadequate investment, whether for maintenance or for new plant and equipment. The costs of an undercapitalized industry can be far greater than the short-run gains from shortfalls in the cost of capital. Moreover, in capital-intensive industries (such as the natural gas distribution industry), systems that take a long time to decay cannot be fixed overnight. Thus, it is in the customers' interest not only to make sure the return investors expect does not exceed the cost of capital, but also to make sure that it does not fall short of the cost of capital, either.

Of course, the cost of capital cannot be estimated with perfect certainty, and other aspects of the way the revenue requirement is set may mean investors expect to earn more or less than the cost of capital even if the allowed rate of return equals the cost of capital exactly. However, a commission that sets rates so investors expect to earn the cost of capital on average treats both customers and investors fairly, and acts in the long-run interests of both groups.

B. Business Risk & Financial Risk: Capital Structure and the Cost of Equity

Q14. Please explain briefly the difference between business risk and financial risk.

A14. Business risk is the risk of a company from its line of business if it used no debt financing. When a firm uses debt to finance its assets, the business risk of the assets is shared between the debt holders and the equity holders, but the equity holders bear more of the risk because debt holders have a prior claim on the company's cash flows. Equity holders are residual claimants, which simply means that equity holders get paid last. In other words, the use of debt imposes financial risk on the equity holders. Therefore, the goal of selecting a sample is to choose companies whose business risk is judged to be comparable to that of the Company's gas distribution operations in Ohio.

Q15. Please explain why it is necessary to report the cost of equity adjusted for capital structure.

A15. Briefly, rate regulation in North America tends to focus on the components of the overall cost of capital, and in particular, on what the "right" cost of equity and capital structure should be. Frequently, there is no consideration of whether the financial risks of the sample companies differ among themselves or differ from the regulated company. The cost of equity estimated using the standard models (e.g., the DCF model or the risk positioning model) reflects both the business and financial risk of the sample companies. The cost of equity estimates for the sample companies will vary, in part, due to small differences in business risk and, in part, due to differences in financial risk. However, the overall cost of capital depends primarily on the business the firm is in, i.e., the business risk of the company's assets, while the costs of the debt and equity components depend not only on this business risk alone but also on the distribution of revenues between debt and equity, i.e. financial risk. The overall cost of capital is thus the more basic concept. The overall cost of capital is constant within a broad middle range of values of capital structures, but the distribution of the costs and risks among debt and equity is not. Appendix E sets out the principles and procedures on which I rely.

C. IMPLICATIONS FOR ANALYSIS

Q16. Please explain the implications of the relationship between capital structure and the cost of equity in your testimony.

A16. The risk equity holders bear, and therefore the cost of equity, depends on the capital structure. As leverage increases, financial risk increases, and hence the required return on equity increases. An approach that estimates the cost of equity for each of the sample firms without explicit consideration of the market value capital structure (i.e., the financial risk) underlying those costs risks material errors. The costs of equity of the sample companies at their actual market-value capital structures do not necessarily reflect the same degree of financial risk as faced by equity holders in the regulated company, and thus could lead to an unfair rate of return if the sample's cost of equity estimate were simply and mechanically applied to the regulated company's capital structure. I avoid this problem by calculating each sample company's ATWACC using its market value capital structure. Using the sample's average overall cost of capital (i.e., the average of the sample companies' ATWACCs) as an estimate of the Company's overall cost of capital, I then determine the corresponding return on equity at the Company's filed regulatory capital structure. This procedure ensures that the capital structure (i.e., financial risk) and the estimated cost of equity are consistent with the market derived sample information.

In the following analyses, I estimate the cost of equity for each of the sample firms using the DCF and risk positioning estimation methods. I use each company's estimated cost of equity along with the Company's estimated 2008 marginal income tax rate[4] and each sample company's cost of debt and market-value capital structure to estimate the company's overall cost of capital. I then calculate the sample's average overall cost of capital for each equity estimation method. Using the procedure discussed above, I then determine the cost of equity at DEO' regulated capital structure that is consistent with the sample's overall cost of capital information for each estimation method.

[4] Ohio levies no state income tax on regulated utilities so the marginal tax rate is equal to the 35 percent federal income tax rate. Instead, utilities pay a gross receipts tax.

Q17. To assess the magnitude of financial risk for a rate regulated company, should you use the market-value or the book-value capital structure?

A17. The market-value capital structure is the relevant quantity for analyzing the cost of equity evidence, which is based on market information.

Q18. Has the need to use market-value capital structures to estimate the cost of equity been widely recognized in the academic community?

A18. Yes. The need to use market-value capital structures to analyze the effect of debt on the cost of equity has been recognized in the financial literature for a long time. For example, the initial reconciliation of the Modigliani-Miller theories[5] of capital structure with the Capital Asset Pricing Model, in Robert S. Hamada, "Portfolio Analysis, Market Equilibrium and Corporate Finance," The Journal of Finance 24: 13-31 (March 1969) works with market-value capital structures. For a more recent presentation of the concept, see, for example, Richard A. Brealey, Stewart C. Myers, and Franklin Allen, *Principles of Corporate Finance*, New York: McGraw-Hill/Irwin 8th ed. (2006) pp. 503-06. Book values may be relevant for some issues, e.g., for covenants on individual bond issues, but as explained in the text, market values are the determinants of the impact of debt on the cost of equity.

Q19. Is the use of market values to calculate the impact of capital structure on the risk of equity incompatible with use of a book-value rate base for a regulated company?

A19. No. The cost of capital is the fair rate of return on regulatory investment (i.e., rate base) for both investors and customers. Most regulatory jurisdictions in North America measure the rate base using the net book value of assets, not current replacement value or historical cost trended for inflation, but the jurisdictions still apply market-derived measures of the cost of equity (such as derived from the DCF or the risk positioning models) to that net book value rate base.

[5] The basic idea of the Modigliani-Miller theories is that the required return on equity increases with the amount of debt in the capital structure, but the overall cost of capital remains constant within a broad middle range of capital structures. See Appendix E, Section I.A. for a more detailed discussion of the Modigliani-Miller theories regarding the effect of debt on a company's overall cost of capital.

The issue here is "what level of risk is reflected in that cost of equity estimate?" That equity risk level depends on the sample company's market-value capital structure, not its book-value capital structure. *That risk level would be different if the sample company's market-value capital structure exactly equaled its book-value capital structure, so the estimated cost of equity would be different, too.*

Q20. Please sum up the implications of this section.

A20. The market risk, and therefore the cost of equity, depends directly on the market-value capital structure of the company or asset in question. It therefore is impossible to compare validly the measured costs of equity of different companies without taking capital structure into account. Capital structure and the cost of equity are unbreakably linked, and any effort to treat the two as separate and distinct questions violates both everyday experience (e.g., with home mortgages as shown in the extended example in Appendix E) and basic financial principles.

Q21. How should a cost of capital analyst implement the principle that the cost of equity changes as financial risk changes?

A21. As discussed further in Appendix E, there has been a great deal of financial research on the effects of capital structure on the value of the firm. One of the key conclusions that results from the research is that no narrowly defined optimal capital structure exists within industries, although the typical range of capital structures does vary among industries.[6] Instead, there is a relatively wide range of capital structures within any industry in which fine-tuning the debt ratio makes little or no difference to the value of the firm, and hence to its overall after-tax cost of capital.

Accordingly, analysts should treat the market-value weighted average of the cost of equity and the after-tax current cost of corporate debt, or the "ATWACC" for short,[7] as

[6] An exception is that very high-risk industries should avoid debt entirely, which makes their optimal capital structure zero percent debt.

[7] This quantity typically is called the "weighted-average cost of capital" or "WACC" in finance textbooks. The textbook WACC equals the *market*-value weighted average of the cost of equity and the *after-tax*, *current* cost of debt. However, rate regulation in North America has a legacy of working with another, and very different, weighted-average cost of capital, the *book*-value weighted average of the cost of equity and

constant within a broad middle range of capital structures for the industry. Sample evidence should be analyzed to determine the sample's average ATWACC, which can be compared across different firms or industries. The economically appropriate cost of equity for a regulated firm is the quantity that, when applied to the *regulatory* capital structure, produces the same ATWACC. That value is the cost of equity that the sample would have had estimation problems aside, if the sample's market-value capital structure had been equal to the regulatory capital structure in question.

Q22. Can you provide an example of the calculation of the cost of equity consistent with the market-determined estimate of the sample's average overall cost of capital?

A22. Yes. Consider the following equation to calculate the ATWACC:[8]

$$ATWACC = r_D \times (1 - T_C) \times D + r_E \times E \qquad (1)$$

where r_D = market cost of debt,
r_E = market cost of equity,
T_C = corporate income tax rate,
D = percentage of debt in the capital structure, and
E = percentage of equity in capital structure.

The cost of equity consistent with overall cost of capital estimate (ATWACC), the market cost of debt and equity, the marginal corporate income tax rate and the amount of debt and equity in the capital structure can be determined by solving equation (1) for r_E.

D. THE COMPANY'S REGULATORY CAPITAL STRUCTURE

Q23. What is the basis of the Company's filed regulatory capital structure in this proceeding?

A23. The regulatory capital structure for the Company in this proceeding is based upon the March 31, 2007 consolidated capital structure of its parent company, Dominion

---

the *before-tax*, *embedded* cost of debt. Accordingly, in regulatory settings it's useful to refer to the textbook WACC as the "ATWACC," or "after-tax weighted-average cost of capital." I follow that practice here.

[8] Note that this equation assumes that only debt and equity are in the capital structure, but preferred equity can be added to the equation if appropriate.

Resources, Inc. ("DRI").[9] The underlying information supporting the filed capital structure is included in Schedules D-1 to D-4 (revised) which are attached to this testimony as Appendix F.[10] As of March 31, 2007, DRI's consolidated capital structure was approximately 44.8 percent equity, 0.8 percent preferred equity and 54.3 percent debt as shown on Schedule D-1.[11]

Q24. What is the source of the data for the capital structure shown on Schedules D-1 to D-4?

A24. The source of the data is DRI's financial information as published in its Form 10-Q as of March 31, 2007. (See footnote 9.)

Q25. Why is it appropriate to use the Company's parent company's consolidated capital structure in this proceeding?

A25. It is appropriate to use DRI's consolidated capital structure for two reasons: 1) going forward, DRI will provide debt and equity financing for Dominion East Ohio, and 2) in the past, the Commission has favored use of the parent company's consolidate capital structure particularly when the parent is the source of financing for the operating company.

However, the use of the ATWACC approach makes the source of the regulatory capital structure less important than it would be if the return on equity were set without regard to the capital structure, because the recommended return on equity changes as the regulatory capital structure changes in order to maintain a constant ATWACC. Note in particular that using the constant ATWACC approach results in no change in the cost to ratepayers as the capital structure changes.

Q26. What information is provided in Schedules D-1 to D-4?

A26. Schedule D-1 provides the consolidated capital structure and the embedded costs of debt and preferred equity based upon the information in Schedules D-2 to D-4. Schedule D-1

[9] Financial information was obtained from DRI's (unaudited) financial statements as reported in their first quarter 2007 Form 10-Q. More detailed information was also provided directly by DRI.

[10] Schedules D-1 to D-4 attached to this testimony are the revised versions not the versions originally filed.

[11] The percentages do not add to 100 percent due to rounding.

also demonstrates the calculation of the 8.72 percent regulatory weighted-average cost of capital ("WACC") for DEO in this proceeding.[12] The regulatory WACC reflects the weighted-average of the embedded costs of long-term debt and preferred stock as well as the 12 percent return on equity that I recommend using the capital structure percentages as weights.

Q27. Please describe the information contained in Schedules D-2 through D-4.

A27. Schedule D-2 entitled "Embedded Cost of Short-Term Debt," Schedule D-3 entitled "Embedded Cost of Long-Term Debt," and Schedule D-4 entitled "Embedded Cost of Preferred Equity," provide the calculations of the embedded costs of short-term debt, long-term debt and preferred equity, respectively.

Q28. Please comment on the parent company information presented in Section D.

A28. The Standard Filing Requirements for Schedule D-3 quantify the embedded cost of long-term debt by dividing Annual Interest Cost by Carrying Value, which is calculated as:

Carrying Value equals	Face Amount Outstanding
	+ Unamortized (Discount) or Premium
	- Unamortized Debt Expense
	+ Unamortized Gain (Loss) on Reacquired Debt

On Schedule PCD-3, DEO includes additional information that it is subsequently reflected in Schedule PCD-1 to establish the overall rate of return requested by the Company. To be more specific, DEO has added a column for Other Related Unamortized Costs in Schedule PCD-3 that reduces the embedded cost of long-term debt by including the effects of pre-issuance hedge gains or losses, embedded option receipts or payments, and swap termination gains or losses.

By reducing the embedded cost of long-term debt by those effects, the Company passes the benefits of those effects on to ratepayers. However, DOE recognizes that the historical approach taken by the Commission would exclude those effects. As a result,

[12] This is the regulatory weighted-average cost of capital discussed earlier because it is the weighted-average of the *before-tax* cost of debt and the after-tax cost of equity in contrast to the ATWACC, which is based on the weighted average of the after-tax costs of debt and equity.

DEO has understated the embedded cost of long-term debt relative to the approach indicated by the Standard Filing Requirements.

Q29. Has the Commission addressed that approach in prior DEO rate cases?

A29. No. The Company did not include such adjustments in prior applications. As a result, the proposed adjustment has not been before the Commission in previous Dominion rate cases.

Q30. Do you have any other comments on Schedules PCD-3 or PCD-4?

A30. Yes. After submitting the Application, the Company noted that the Other Related Unamortized Cost adjustment for the debt issue noted on line 52 was incorrect. Appendix F to my testimony includes updated PDC Schedules with the data corrected.

In addition to the PCD-3 information, a sign error was noted on Schedule PCD-4, which nominally adjusted the embedded cost of preferred stock. However, the weighted cost for that component of capital was unaffected due to the small portion of the overall capital structure that is comprised of preferred stock. Nonetheless, the updated Schedule D-4 included in Appendix F also incorporates the correction of that error.

III. COST OF CAPITAL METHODOLOGY

Q31. How is this section of your testimony organized?

A31. As noted in Section II, I estimate the cost of capital using a sample of comparable risk companies. This section first outlines the steps involved in selecting the benchmark sample, in determining the market-value capital structures, and in estimating the sample companies' costs of debt. It then turns to the procedures for estimating the cost of equity and describes the two cost of equity estimation methodologies used in this testimony, the DCF method and the risk positioning approach. These are the foundations of my cost of capital calculations which I present in the following section and which I use to derive a recommended cost of equity for DEO at the regulatory capital structure.

A. SAMPLE SELECTION

Q32. What is the goal of the sample selection process?

A32. The goal of the sample selection process is to select companies with comparable business risk to the regulated company. The overall cost of capital for a part of a company depends on the risk of the business in which the part is engaged, not on the overall risk of the parent company on a consolidated basis. According to financial theory, the overall risk of a diversified company equals the market-value-weighted average of the risks of its components.

Estimating the cost of capital for the Company's regulated natural gas distribution assets is the subject of this proceeding. The ideal sample would be a number of publicly traded "pure play" companies that distribute natural gas and have a requirement to serve as providers of last resort (PoLR). "Pure Play" is an investment term referring to companies with operations only in one line of business. Publicly traded firms, firms whose shares are freely traded on stock exchanges, are ideal because the best way to infer the cost of capital is to examine evidence from capital markets on companies in the given line of business.

In this case, a sample of companies whose operations are concentrated solely in the regulated distribution portion of the natural gas industry would be ideal. So, I start with the universe of natural gas distribution utility companies covered by *Value Line*. This resulted in an initial group of 23 companies, to which I added Vectren Corporation because it is often viewed as a natural gas LDC. Companies were first eliminated if their operating regions were outside of the continental USA. I then applied my standard selection criteria to narrow the sample to those companies likely to have reliable cost of equity estimates. This resulted in a benchmark sample of ten companies. Financial characteristics of the sample companies are outlined in Table 1 below. Additional details on the sample selection process are discussed below and in Appendix B.

B. CAPITAL STRUCTURE & THE COST OF DEBT

1. Market-Value Capital Structure

Q33. What capital structure information do you require?

A33. For reasons discussed in Appendix E, explicit evaluation of the market-value capital structures of the sample companies is vital for a correct interpretation of the market evidence on the return on equity. This requires estimates of the market values of common equity, preferred equity and debt, and the current market costs of preferred equity and debt.

Q34. Please describe how you calculate the market values of common equity, preferred equity and debt.

A34. I estimate the capital structure for each sample company by estimating the market values of common equity, preferred equity and debt from the most recent publicly available data. The details are in Appendix B.

Briefly, the market value of common equity is the price per share times the number of shares outstanding. For the risk positioning approach, I use the last five trading days of each year to calculate the market value of equity for the year. I then calculate the average capital structure over the corresponding five-year period used to estimate the "beta" risk measures for the sample companies.[13] This procedure matches the estimated beta to the degree of financial risk present during its estimation period. In the DCF analyses, I use the average closing stock price over the 15 trading days ending on the day that the earnings growth rate forecasts are obtained from Bloomberg.[14]

The market value of debt is estimated at its book value adjusted by the difference between the "estimated fair (market) Value" and the "carrying cost" of long-term debt reported in each company's 10-K.[15] The market value of preferred stock for the samples

[13] *Value Line* uses five years of historical data to estimate its forecasted betas.

[14] Forecasts were obtained on June 11, 2007 for all companies in the sample.

[15] The book value of debt from Bloomberg includes all interest-bearing financial obligations that are not current and includes capitalized leases and mandatory redeemable preferred and trust preferred securities in

is set equal to its book value because the percent of preferred stock in the capital structures of the sample companies is relatively small compared to the debt and common equity components.

2. Market Costs of Debt and Preferred Equity

Q35. How do you estimate the current market cost of debt?

A35. The market cost of debt for each company is set equal to the yield on an index of public utility bonds that have the same credit rating, and the yield is reported by Bloomberg's for an index of public utility company bonds with the same S&P rating. The DCF analyses use the current credit rating whereas the risk positioning analyses use the current yield of a utility bond that corresponds to the five-year average debt rating of each company so as to match consistently the horizon of information used by *Value Line* to estimate company's beta.

Q36. How do you estimate the market cost of preferred equity?

A36. For each company with preferred stock, the cost of preferred equity for each company is set equal to the yield on an index of preferred stock as reported in the Mergent Bond Record[16] corresponding to the S&P rating of that company's debt.

3. Risk-Free Interest Rate Forecast

Q37. What is the risk-free rate?

A37. The risk-free rate is the interest rate that can be earned with certainty. A common measure of this rate is the yield on the government's Treasury bills and bonds. This rate is usually significantly below the rate which other borrowers pay for debt.

---

accordance with FASB 150 effective June 2003. See Bloomberg definition of long-term debt for additional detail.

[16] Published monthly, *Mergent's Bond Record* offers a comprehensive review of over 68,000 bond issues including coverage of corporate, government, municipal, industrial development/environmental control revenue and international bonds, plus structured finance and equipment trust issues, medium-term notes, convertible issues, preferred stocks and commercial paper issues.

Q38. How do you obtain the forecasts of the risk-free interest rates over the period the utility rates set here are to be in effect?

A38. I obtain these forecast rates using data provided by Bloomberg. In particular, I use the reported government debt yields from the "constant maturity series". This information is displayed in Panels A and B of Table No. MJV-9.

Q39. What values do you use for the short-term and long-term risk-free interest rates?

A39. I use a value of 4.1 percent for the short-term risk-free interest rate and a value of 5.1 percent for the long-term risk-free interest rate as the benchmark risk-free interest rates in the equity risk premium analyses. The short-term interest rate forecast is constructed by using historical yield curve data to find the long-run average implied maturity term premia on government securities, and combining these with recent yield curve data. Details of their calculation can be found in the Workpapers to Table No. MJV-9.

C. COST OF EQUITY METHODS

Q40. How do you estimate the cost of equity for your sample companies?

A40. Recall the definition of the cost of capital from the outset of my testimony: the expected rate of return in capital markets on alternative investments of equivalent risk. My cost of capital estimation procedures address three key points implied by the definition:

1. Since the cost of capital is an expected rate of return, it cannot be directly observed; it must be inferred from available evidence.

2. Since the cost of capital is determined in capital markets (e.g., the New York Stock Exchange), data from capital markets provide the best evidence from which to infer it.

3. Since the cost of capital depends on the return offered by alternative investments of equivalent risk, measures of the risks that matter in capital markets are part of the evidence that needs to be examined.

Q41. How does the above definition help in cost of capital estimation?

A41. The definition of the cost of capital recognizes a tradeoff between risk and expected return, plotted above in Figure 1, the security market line. Cost of capital estimation

methods take one of two approaches: (1) they try to identify a comparable-risk sample of companies and to estimate the cost of capital directly; or (2) they establish the location of the security market line and estimate the relative risk of the security, which jointly determine the cost of capital. In terms of Figure 1, the first approach focuses directly on the vertical axis, while the second focuses both on the security's position on the horizontal axis and on the position of the security market line.

The first type of approach is more direct, but ignores the wealth of information available on securities not thought to be of precisely comparable risk. The "discounted cash flow" or "DCF" model is an example. The second type of approach, sometimes known as "equity risk premium approach," requires an extra step, but as a result can make use of information on all securities, not just a very limited subset. The Capital Asset Pricing Model ("CAPM") is an example. While both approaches can work equally well if conditions are right, one may be preferable to the other under a given set of circumstances. In particular, approaches that rely on the entire security market line (e.g., the risk positioning model) are less sensitive to deviations from the assumptions that underlie the model, all else equal. In this proceeding, I examine sample evidence from both the DCF and risk positioning models.

1. The Risk Positioning Approach

Q42. Please explain the risk positioning method.

A42. The risk positioning method estimates the cost of equity as the sum of a current interest rate and a company specific risk premium. It is therefore sometimes also known as the "risk premium" approach. This approach may sometimes be applied informally. For example, an analyst or commission may check the spread between interest rates and what is believed to be a reasonable estimate of the cost of capital at one time, and then apply that spread to changed interest rates to get a new estimate of the cost of capital at another time.

More formal applications of the risk positioning approach take full advantage of the security market line depicted in Figure 1: they use information on all securities to

identify the security market line and derive the cost of capital for the individual security based on that security's relative risk. This reliance on the entire security market line makes the method less vulnerable to the kinds of problems that arise for the DCF method, which relies on one stock at a time. The risk positioning approach is widely used and underlies most of the current research published in academic journals on the nature, determinants and magnitude of the cost of capital.

Section I of Appendix C to this testimony provides more detail on the principles that underlie the risk positioning approach. Section II of Appendix C provides the details of the risk positioning approach empirical estimates I obtain.

Q43. How are the "more formal" applications of risk positioning approach implemented?

A43. The first step is to specify the current values of the parameters that determine the security market line. The second is to determine the security's or investment's relative risk. The third is to specify exactly how the parameters combine to produce the security market line, so the company's cost of capital can be calculated based on its relative risk. All of these elements and how they relate are usefully formulated in the framework of the CAPM.

a) The Capital Asset Pricing Model

Q44. Please start with the CAPM, by describing the model.

A44. As noted above, the modern models of capital market equilibrium express the cost of equity as the sum of a risk-free rate and a market risk premium. The CAPM is the longest-standing and most widely used of these theories. The CAPM states that the cost of capital for an investment, *s*, (e.g., a particular common stock) is given by the following equation:

$$k_s = r_f + \beta_s \times MRP \qquad (2)$$

where k_s is the cost of capital for investment *s*; r_f is the risk-free rate, β_s is the beta risk measure for the investment *s*; and *MRP* is the market risk premium.

The CAPM relies on the empirical fact that investors price risky securities to offer a higher expected rate of return than safe securities do. It says that the security market line starts at the risk-free interest rate (that is the return on a zero-risk security, the y-axis intercept in Figure 1, equals the risk-free interest rate). It further says that the risk premium over the risk-free rate equals the product of beta and the risk premium on a value-weighted portfolio of all investments, which by definition has average risk.

b) The Empirical Capital Asset Pricing Model

Q45. What other equity risk premium model do you use?

A45. Empirical research has long shown that the CAPM tends to overstate the actual sensitivity of the cost of capital to beta: low-beta stocks tend to have higher risk premia than predicted by the CAPM and high-beta stocks tend to have lower risk premia than predicted. A number of variations on the original CAPM theory have been proposed to explain this finding, but this finding can also be used to estimate the cost of capital directly, using beta to measure relative risk without simultaneously relying on the CAPM.

The second model makes use of these empirical findings. It estimates the cost of capital with the equation, where α is the "alpha" adjustment of the risk-return line, a constant,

$$k_s = r_f + \alpha + \beta_s \times (MRP - \alpha) \qquad (3)$$

and the other symbols are defined as above. I label this model the Empirical Capital Asset Pricing Model, or "ECAPM." The alpha adjustment has the effect of increasing the intercept but reducing the slope of the security market line in Figure 1, which results in a security market line that more closely matches the results of empirical tests.

Q46. Why is it appropriate for you to use the empirical CAPM?

A46. Although the CAPM is still the most widely used cost of capital estimation model, it has not been completely satisfactory as an empirical model; however, its short-comings are directly addressed by the ECAPM. The ECAPM recognizes the consistent empirical observation that the CAPM underestimates (overestimates) the cost of capital for low (high) beta stocks. In other words, the ECAPM is based on the recognition that the actual

slope of the risk-return tradeoff is flatter than predicted and the intercept higher based upon repeated empirical tests of the CAPM. The alpha parameter (α) in the ECAPM adjusts for this fact. The difference between the CAPM and the type of relationship identified in the empirical studies is depicted in Figure 2.

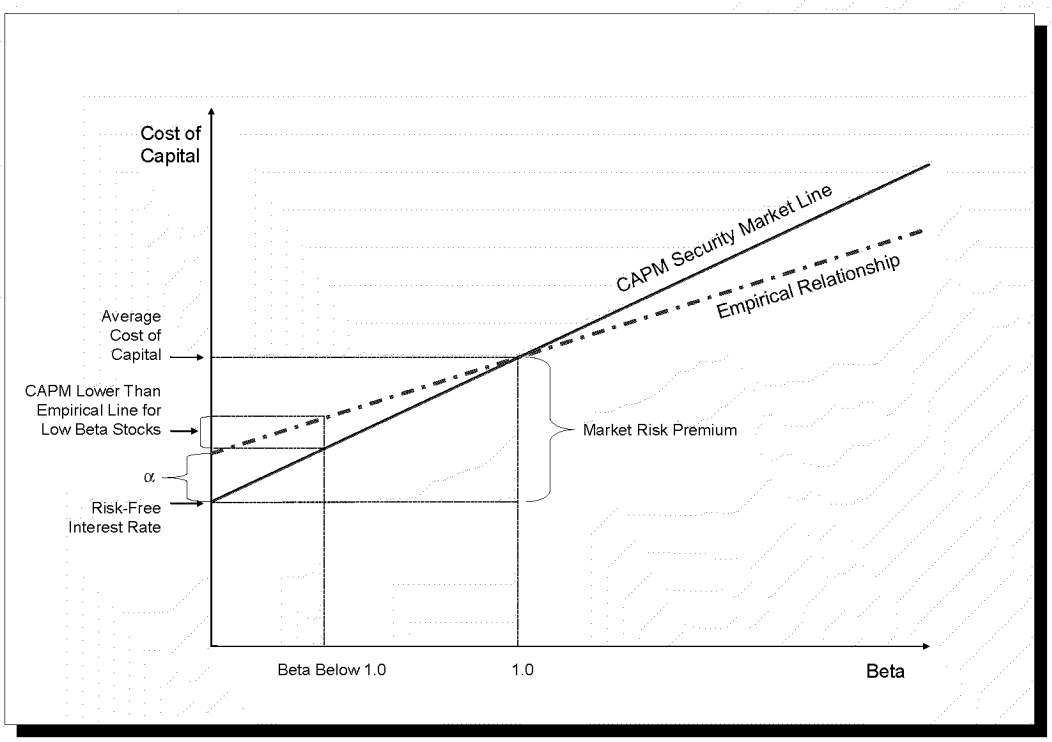

Figure 2: The Empirical Security Market Line

Research supports values for α of one to seven percent when using a short-term interest rate. I use baseline values of α of 2 percent for the short-term risk-free rate and 0.5 percent for the long-term risk-free rate. I also conduct sensitivity tests for different values of α. For the short-term risk-free rate I use values for α of 1, 2 and 3 percent. These α values are lower than would be justified by the magnitude of the correction revealed in the tests of the CAPM. For the long-term risk-free rate, the corresponding α values are 0, 0.5 and 1.5 percent. The use of a long-term risk-free rate incorporates some of the desired effect of using the ECAPM. That is, the long-term risk-free rate version of the security market line has a higher intercept and a flatter slope than the short-term risk-free version which has been extensively tested. Thus, I do not need to make the same degree of refinement when I use the long-term risk-free rate. Please see Table No. MJV-

C1 in Appendix C for a summary of the empirical evidence on the size of the required adjustment necessary to better match the results of the empirical tests.

2. Discounted Cash Flow Method

Q47. Please describe the discounted cash flow approach.

A47. The DCF model takes the first approach to cost of capital estimation, i.e., to attempt to estimate the cost of capital in one step. The method assumes that the market price of a stock is equal to the present value of the dividends that its owners expect to receive. The method also assumes that this present value can be calculated by the standard formula for the present value of a cash flow stream:

$$P = \frac{D_1}{(1+k)} + \frac{D_2}{(1+k)^2} + \frac{D_3}{(1+k)^3} + \cdots + \frac{D_T}{(1+k)^T} \quad (4)$$

where "P" is the market price of the stock; "D_t" is the dividend cash flow expected at the end of period t (i.e., subscript period 1, 2, 3 or T in the equation); "k" is the cost of capital; and "T" is the last period in which a dividend cash flow is to be received. The formula just says that the stock price is equal to the sum of the expected future dividends, each discounted for the time and risk between now and the time the dividend is expected to be received.

Very often, when the DCF is applied in regulatory proceedings, very strong (i.e., unrealistic) assumptions are used that yield a simplification of the standard formula, which then can be rearranged to estimate the cost of capital. Specifically, it is assumed that investors expect a dividend stream that will grow *forever* at a steady rate, and if so, the market price of the stock will be given by a very simple formula,

$$P = \frac{D_1}{(k-g)} \quad (5)$$

where "D_1" is the dividend expected at the end of the first period, "g" is the perpetual growth rate, and "P" and "k" are the market price and the cost of capital, as before. Equation (5) is a simplified version of equation (4) that can be solved to yield the well known "DCF formula" for the cost of capital:

$$k = \frac{D_1}{P} + g$$
$$= \frac{D_0 \times (1+g)}{P} + g \qquad (6)$$

where "D_0" is the current dividend, which investors expect to increase at rate g by the end of the next period, and the other symbols are defined as before. Equation (6) says that if equation (5) holds, the cost of capital equals the expected dividend yield plus the (perpetual) expected future (forever constant) growth rate of dividends. I refer to this as the simple DCF model. Of course, the "simple" model is simple because it relies on very strong (i.e., very unrealistic) assumptions.

Q48. Are there other versions of the DCF models besides the "simple" one?

A48. Yes. The constant growth rate DCF model requires that dividends and earnings grow at the same rate for companies that earn their cost of capital on average.[17] It is inconsistent with the theory on which the model is based to have different growth rates in earnings and dividends over the period when growth is assumed to be constant. If the growth in dividends and earnings were expected to vary over some number of years before settling down into a constant growth period, then it would be appropriate to estimate a multistage DCF model. In the multistage model, earnings and dividends can grow at different rates, but must grow at the same rate in the final, constant growth rate period. A difference between forecasted dividend and earnings rates therefore is a signal that the facts do not fit the assumptions of the simple DCF model.

So, I consider a variant of the DCF model that relies on slightly less strong assumptions in that it allows for varying dividend growth rates in the near term before assuming a perpetual growth rate beginning in year eleven. I use the forecast growth of GDP as the forecast of the long-term growth rate, i.e. year eleven on. This is a "multistage" variant

[17] Why must the two growth rates be equal in a steady-growth DCF model? Think of earnings as divided between reinvestment, which funds future growth, and dividends. If dividends grow faster than earnings, there is less investment and slower growth each year. Sooner or later dividends will equal earnings. At that point, growth is zero because nothing is being reinvested (dividends are constant). If dividends grow slower than earnings, each year a bigger fraction of earnings are reinvested. That makes for ever faster growth. Both scenarios contradict the steady-growth assumption. So if you observe a company with different

of the DCF method. The DCF models are described in detail in Section I.A of Appendix D. (Section II of Appendix D provides the details of my empirical DCF results.)

Q49. What are the merits of the DCF approach?

A49. The DCF approach is conceptually sound if its assumptions are met, but can run into difficulty in practice because those assumptions are so strong[18], and hence so unlikely to correspond to reality. Dividends, earnings and prices are unlikely to grow at a constant rate literally forever. Two conditions are also well known to be necessary for the DCF approach to yield a reliable estimate of the cost of capital: the variant of the present value formula that is used must actually match the variations in investor expectations for the growth of dividends, and the growth rate(s) used in that formula must match current investor expectations. Less frequently noted conditions may also create problems (see Appendix D for details).

Q50. Is estimating the "right" dividend growth rate the most difficult part for the implementation of the DCF approach?

A50. Yes. Finding the right growth rate(s) is the usual "hard part" of a DCF application. The original approach to estimation of *g* relied on average historical growth rates in observable variables, such as dividends or earnings, or on the "sustainable growth" approach, which estimates *g* as the average book rate of return times the fraction of earnings retained within the firm. The use of historical growth rates versus the use of analysts' estimates is frequently the source of heated debated in regulatory proceedings, but it is highly unlikely that these historical averages over periods with widely varying rates of inflation and costs of capital will equal current growth rate expectations. As discussed above, this is particularly true for the natural gas industry at present because of the changes the industry is undergoing as a result of the highly volatile price of gas, the possible imposition new environmental and safety regulations and the emphasis on conservation and demand reduction. The increase in the numbers of mergers and

---

expectations for dividend and earnings growth, you know the company's stock price and its dividend growth forecast are inconsistent with the assumptions of the steady-growth DCF model.

[18] In this context "strong" means that the assumption is unlikely to match reality and that it also has a substantial impact on the model's results.

acquisition in the industry adds an additional concern for the applicability of the model to the industry at this time. In addition, the electric industry is a major source of demand for natural gas, and that industry is also undergoing a period of great uncertainty regarding the ultimate structure of the industry. Similar environmental and conservation pressures are affecting the electric industry and the resulting uncertainty of the demand for electricity will have a ripple effect on the natural gas industry. This is not a description of the stable conditions necessary for the reliable implementation of the DCF model.

IV. DEO'S COST OF CAPITAL

A. THE COMPANY'S OPERATIONS AND RISKS

Q51. Please describe the Company's operations in Ohio.

A51. As explained in the testimony of Company witness Jeffrey Murphy, DEO serves approximately 1.2 million customers in over 400 communities in northeastern, southeastern and western Ohio using its over 19,000 miles of pipelines and related distribution, transmission, storage and gathering assets.

B. SAMPLE SELECTION

Q52. How did you select your sample of natural gas LDCs?

A52. The goal was to create a sample of companies whose primary business is as a regulated natural gas LDC with business risk generally similar to that of DEO's operations in Ohio. I considered the universe of 23 companies classified by the *Value Line Investment Survey Plus* as natural gas LDCs, and added Vectren Corporation to my sample because it is often viewed as a natural gas LDC.[19] Vectren is a highly regulated company involved in both gas and electric distribution activities, but more of its regulated assets are invested in the gas distribution operations.[20] This company is also covered by *Value Line*, but is

[19] The 24 companies are from Value Line Investment Survey Plus, June 11, 2007.

[20] Vectren Utility Holdings, Inc.'s 2006 10-K reveals that about 57 percent of its assets are regulated natural gas distribution assets and 37 percent are regulated electric assets. Because it has a substantial amount of regulated electric utility operations, I exclude it from the sub-sample of companies I consider to be the most

classified as an Electric Utility due to its regulated electric operations.[21] I required that the sample companies have a high percentage of assets devoted to the regulated natural gas distribution line of business. I then eliminated companies by applying additional selection criteria designed to remove companies with unique circumstances which may bias the cost of capital estimates.

Specifically, I eliminated all companies whose S&P bond rating as reported by Bloomberg was not investment grade, i.e., less than BBB- or which were not rated. To guard against measurement bias caused by "thin trading," I also restricted the sample to companies with total operating revenues greater than $300 million in 2006 as reported by Bloomberg.[22] Companies that had a large merger during the period January 2004 to June 2007 (i.e., just over the past three years) were also generally removed from the sample, although two companies which would otherwise not survive the process were included since their primary M&A activity occurred in 2004. These two companies were Atmos Energy and AGL Resources, and they were subsequently excluded from the sub-sample of companies I believe to have the fewest data issues. The screen for M&A activity was primarily done by scanning each company's news history on Bloomberg and a search of company web pages.[23] Finally, I required that the companies have historical data available from Bloomberg for the relevant period and had no dividend cuts or restatement of financial statements in the past five years, since the latter can be signs of financial distress and could cause the earnings growth rates or beta estimates to be biased.

The final sample consists of ten gas LDCs, from which I also consider a sub-sample of five companies with the fewest data issues that may affect cost of capital estimates. Table No. MJV-2 reports the estimated share of total assets for each company devoted to

---

representative of the natural gas distribution line of business and to be most free of characteristics that may bias cost of equity estimates.

[21] The 23 companies are from *Value Line Investment Survey Plus*, dated June 15, 2007. Vectren's *Value Line* report is dated June 29, 2007.

[22] Data were reviewed during the second week of June 2007.

[23] Company web pages were searched in December 2003 for M&A activities during the 2001-2003 period, in July 2006 for M&A activities during the period 2004 through July 2006, and in December 2006 for the period August through December 2006.

regulated activities in 2006. Additional details on the sample selection process can be found in Appendix B. Some of the financial characteristics of the sample companies are displayed in Table 1 below.

Table 1: Financial Characteristics of the Sample Companies

Company		S&P Business Classification	Revenue (2006) ($MM)	Regulated Utility Assets	Market Cap. (2006) ($MM)	S&P Bond Rating (2007)	Beta	Long-Term Growth Estimate
		[1]	[2]	[3]	[4]	[5]	[6]	[7]

C. Potential Data Problems with the Sample

Q53. Do you have concerns regarding the data for the gas LDC sample?

A53. Possibly. Although still investment grade, Southwest Gas is at the bottom of the scale of investment grade credit ratings and has a relatively low average equity thickness over the past five years – 41.8 percent compared to 63 percent for the remaining companies. Closer investigation shows that Southwest Gas's capital structure has been shifting rapidly towards equity over the last five years, with a level of about 50 percent over the most recent two years. The Laclede Group's market capitalization of $753 million is a bit smaller than the average of the group, but with revenues of more than $1.9 billion, it is still a large company. South Jersey Industries' revenues are less than $1 billion and smaller than its market capitalization. In 2006, Piedmont Natural Gas restated some portions of its 2003-2005 financial reports. Although this can generally lead to less reliable estimates from the equity estimation models, the restatements were not caused by fraudulent activities but were due to an accounting error in the classification of hedging amounts. This type of reclassification would not be expected to change the value of the firm and prices did not show any erratic behavior in the period surrounding the announcement of this reclassification. As noted earlier, the industry has experienced a sustained level of merger and acquisition activity over the last five years that has implication for the stability of the industry and the actual cash flows that underlie the prices paid for the stocks of these companies.

Due to the concerns with some of the companies in the sample, I also report the results for a sub-sample of the gas LDC sample that consists of companies with no material data issues. Of course, the selection of such a sub-sample does not address possible biases in DCF estimates due to expected cash flows reflected in the stock price but not in the data used to estimate DCF dividends and growth rates; to the contrary, purer play companies may be more attractive targets, which would produce and even greater downward bias in their DCF calculations.

D. Relative Risk of the Sample Compared to DEO

Q54. Could you please summarize the general characteristics of the companies in the sample and those of the Company's operations in Ohio?

A54. Yes. The sample consists of ten gas LDCs with generally similar risk characteristics to those of DEO. Table 2: Risk Characteristics of the Sample companies summarizes information related to the risks of the sample and of the Company's operations in Ohio. Like the Company's operations, they all have some form of gas-cost adjustment clause, which either removes or significantly reduces their exposure to this risk. In their 10-Ks, all sample companies report that they engage in hedging activities to further reduce the risk of large changes in the price of natural gas. Eight of the ten sample companies have weather adjustment clauses, which Dominion East Ohio does not.

I have been informed by DEO that the Company is in the process of transitioning out of the merchant function of purchasing gas for its customers. In the first phase of that process, its gas cost recovery rider is being replaced by a Standard Service Offer with supply acquired through a PUCO-approved auction. However, Dominion remains the Provider of Last Resort if a supplier defaults on its obligation to provide service. As a result, while Dominion's traditional risk of under recovery of gas commodity costs will be reduced, it still faces operational and financial risks associated with that POLR obligation. Dominion also has a bad debt tracker that reduces its exposure to the inability of its customers to pay for service.

As discussed in the direct testimony of Company witness Jeffrey Murphy, Dominion still faces significant risks associated with the overall economic climate and, in particular, the economy within its service territory. Dominion receives considerable revenue from its commercial and industrial base of customers. Much of its industrial base is centered on the steel and automotive sectors, which can readily relocate production elsewhere in North America or offshore and which can face ongoing structural problems given the age of the production facilities.

Unlike many gas LDCs, DEO operates an extensive transmission system, which was affected by the provisions of the Pipeline Safety Improvement Act of 2002 that required

transmission pipeline operators to develop extensive integrity management programs involving substantial O&M and capital expenses. Given the age of its system, DEO will also be heavily impacted by final rules that result from the notice of proposed rulemaking expected from the Department of Transportation's Pipeline and Hazardous Materials Safety Administration regarding distribution pipeline integrity management programs.

Recently enacted Ohio minimum gas service standards pose additional business risk to DEO as they entail increased service levels in a variety of areas ranging from call center response times to appointment scheduling and complaint handling. Even though the Company may not have historically experienced significant problems in providing quality natural gas service, there is uncertainty imposed by the new standards.

DEO is proposing a Sales Reconciliation Rider to address conservation-related impacts on base revenues, which will decouple gas usage from the company's ability to meet its revenue requirements. It does not, however, currently have, nor has it proposed, a weather normalization clause to eliminate the effect of variations from normal weather on its earnings. Gas LDCs throughout the country have received approval to include such clauses in their rates and charges for utility service, which serves to reduce their single largest business risk. By not having such a clause, DEO is at greater risk than many other comparable LDCs in this regard.

Although DEO has begun the process of exiting the traditional regulated merchant function, that transition is far from complete, and the Commission has retained the right to place the company back in its traditional Gas Cost Recovery role if that transition does not go as well as planned. Transitions can sometimes pose more risk than maintaining the status quo. Thus, the Company's risks, which include an ongoing responsibility to act as the provider of last resort, are still substantial and may, in fact, be greater in the short-term than comparable companies that are not undergoing such a dramatic transition. If the transition turns out as expected, DEO will be less risky than the sample on average, but if the transition turns out differently than expected, the Company's business risk may be greater than, not less than, the sample on average.

Table 2: Risk Characteristics of Sample Companies

Company [1]	Fuel Cost Adjustment [2]	Weather Normalization [3]	Fuel Cost Hedging [4]	Storage Facilities [5]	S&P Business Profile [6]

E. COST OF CAPITAL ESTIMATES

Q55. Please summarize the results of the risk positioning and DCF methodologies in estimating the average cost of capital for the benchmark sample and the implications for DEO's cost of equity?

A55. Table 3 summarizes the sample average ATWACCs derived from the risk positioning and DCF models, along with the implied cost of equity for the Company at its filed regulatory capital structure with 44.8 percent equity.

Table 3: Cost of Equity Results

Regulatory Capital Structure: *44.8% Equity / 0.8% Preferred / 54.3% Debt* *2008 Tax Rate* *35.0%*

	METHODS								
	RISK POSITIONING (Long-Term Risk-Free Rate)			RISK POSITIONING (Short-Term Risk-Free Rate)				DCF	
	CAPM	α = 0.5%	α = 1.5%	CAPM	α = 1%	α = 2%	α = 3%	Simple	Multi

[1],[2] See Tables 1 and 2 above for a summary of the sample and its characteristics.
[3] See Appendix C for details on the Risk Positioning parameters used in the estimates, and Appendix D for the DCF parameters and additional implementation details.

Q56. How did you determine a representative tax rate to use in your cost of capital estimation?

A56. DEO's estimated marginal income tax rate for 2008 was set the Federal corporate tax rate. Ohio does not levy a corporate income tax on regulated utilities.

Q57. How are the cost of equity estimates derived from the risk positioning approach for the benchmark sample?

A57. I derive two sets of risk-positioning estimates, one using long-term forecasts of the risk-free rate and market risk premium, and one using short-term forecasts. My long-term

interest rate forecast is 5.1 percent and the corresponding estimated market risk premium is 6.5 percent. When using the short-term risk-free rate of 4.1 percent, the estimated MRP is 8.0 percent. Details on the derivation of these forecasts can be found in Appendix C.

For each estimated risk-free rate, the two risk positioning models (CAPM and ECAPM) are estimated utilizing the different values of the ECAPM parameter (0.5% and 1.5% for the long-term model and 1%, 2%, and 3% for the short-term model). I therefore obtain three long-term and four short-term estimates of each sample company's cost of equity. The results using the long-term risk-free rate are displayed in Table MJV-10, Panel A, and the results using the short-term risk-free rate are displayed in Table MJV-10, Panel B. Next, the cost of equity estimates are combined with each company's estimated cost of debt and preferred equity to calculate the company's ATWACC using each company's market value capital structure. These calculations and the resulting sample average ATWACCs are presented in Table No. MJV-11. Panels A-C rely on the cost of equity estimates from the long-term version of the model, while Panels D-G utilize the estimates from the short-term version of the model. The sample average ATWACCs and costs of equity at the Company's 44.8 percent equity capital structure for each risk positioning cost of equity estimate are displayed in Table No. MJV-12. These results are summarized in Table 3 above.

Q58. What are the DCF estimates for the benchmark sample?

A58. For each sample company, cost-of-equity estimates are calculated for the two versions of the DCF method, the simple DCF model and multistage DCF model. The DCF estimates for each company are displayed in Table No. MJV-6, Panel A (simple DCF) and Panel B (multistage DCF). The sample and sub-sample average ATWACC for each method is calculated in Table No. MJV-7, and these are used in Table No. MJV-8 to derive the return on equity at the Company's 44.8 percent equity capital structure for each estimation method (see also Table 3 above). Table 3 shows the estimated cost of equity to be 10.3 percent (simple DCF model) and 10.7 percent (multistage DCF model) for the full sample, and 9.9 percent (simple DCF) and 10.6 percent (multistage DCF) for the sub-sample. The estimates from the simple and multistage DCF models are about 2.5 to 3.0

percent lower than the estimates from risk-positioning models, for both the long-term term and short-term versions of the risk positioning model. (See Table 3: Cost of Equity Results above).

V. CONCLUSIONS

Q59. What are your conclusions from the DCF model regarding the cost of equity at the Company's 44.8 percent equity ratio?

A59. The estimated costs of equity from the simple DCF model are somewhat lower than the estimates from the multistage model, and significantly lower than any of the risk positioning model estimates. The simple DCF model relies on company-specific growth rate forecasts, but those forecasts are likely to be downward biased due to concerns about volatile natural gas prices, the series of mergers and acquisitions and potential changes in the industry. The high level of recent mergers and acquisitions is likely to have increased the market prices of the sample companies if investors anticipate potential interest in additional acquisitions in the industry, and earnings growth rates are likely to be affected following a merger as the new company consolidates its operations. Together these factors will tend to reduce the DCF estimates. In addition, the simple DCF results are unreliable because the long-run growth rate forecast drives the results, and there are no objective data on the long-run growth rate investors truly expect, or on when the industry is expected to settle down into some sort of stable-growth equilibrium. The somewhat more reliable multistage DCF estimate, after adjustment for financial risk, is about 10.7 percent which is about 40 to 80 basis points higher than the simple DCF estimates from the full sample and sub-sample, but about 200 to 230 basis points lower than the long-term risk positioning estimates. The multistage model is also affected by the same uncertainties about the industry that make the simple DCF model unreliable at this time. Although I do not put much weight upon the DCF model results in my recommended cost of equity for DEO, I believe that DCF cost capital estimates provide a useful check on the risk positioning results.

Q60. Do you have any comments regarding the results of the risk positioning models?

A60. As noted earlier, the risk positioning results are also summarized in Table 3 above. At this time, the estimated costs of equity for the long-term version of the model are lower than for the short-term version of the model. Of those results, the CAPM values deserve the least weight, because this method does not adjust for the empirical finding that the cost of capital is less sensitive to beta than predicted by the CAPM (which my testimony considers by using the ECAPM). Conversely, the ECAPM numbers deserve the most weight, because this method adjusts for the empirical findings. The cost of equity estimates using the long-term risk free rate and adjusted for a capital structure with a 44.8 percent equity ratio range from 12.7 to 13.0 percent for the full sample, and from 12.4 to 12.7 percent for the sub-sample. For the estimates based upon the short-term risk-free rate, the estimates range from 13.0 to 13.7 percent and from 12.7 to 13.4 percent for the full sample and sub-sample respectively.

The estimates based upon the short-term risk-free rate are about 30 to 70 basis points higher on average than the estimates using the long-term risk-free rate. This is partially due to the fact that the yield curve is currently less steep than it has been historically, i.e., the yield on long-term Treasury bonds only marginally exceeds the yield on short-term Treasury bills. Panel A of Table No. MJV-9 shows that 30-day Treasury bills are currently yielding an average of 4.86 percent compared to only 5.14 percent for long-term Treasury bonds. This 28 basis point difference between the yield on short-term and long-term Treasury securities is unusual. Yields on long-term Treasury bonds have averaged about 150 basis points more than the yields on 30-day Treasury bills over the last 80 years (see Workpaper #1, Panel B to Table No. MJV-9). It should be noted that although the current difference is relatively small by historical standards, it represents a movement towards normalcy from the flat and even "inverted" yield curves observed last year and early this year.

Treasury yields have exhibited a number of unusual behaviors over the past few years in response to a multitude of factors, from the uncertainty after 9/11 and a ballooning U.S. debt and trade deficit (which among other things led to the reintroduction of 30 year Treasury bonds), to a remarkable resiliency of the U.S. economy that continues to

outperform expectations. The yield on short-term Treasury bills reflects the efforts by the Federal Reserve ("Fed") to prevent the rate of inflation from increasing any further, while at the same time providing enough liquidity for economic growth. If the Fed believes that inflation is not yet contained, short-term rates are likely to increase further. On the other hand, if inflation is judged to be under control, short-term rates may decline as fears of recession replace those of inflation. At this time, a great deal of additional uncertainty surrounds the policy that will be followed by the Fed in the near term as a result of a potential deterioration in credit markets and wavering confidence in future economic performance. This fear – triggered by widespread defaults in the U.S. subprime mortgage market and fueled further by negative job growth statistics– may require the Fed to maintain or even lower rates in order to avoid a large order macroeconomic downturn. On the other hand, the Fed does not want to give the appearance that it is bailing out investors who simply realized bad bets in the sub-prime market. As such, it is currently walking a fine line that could tip in either direction as events unfold. Because of this near term uncertainty, I believe that the estimates using the long-term risk-free rate are more reliable at this time.

Q61. Given the results of the two models, what is your conclusion regarding the cost of equity for DEO?

A61. The results for the somewhat more reliable multistage version of the DCF model are an average ATWACC of about 7.1 percent for both the full- and sub-sample, with a corresponding cost of equity of between 10.6 and 10.7 percent, but as noted above, I do not believe that the DCF results are reliable at this time, so I rely primarily on the results from the risk positioning model. At best, the DCF estimates serve as a floor for the estimates of the cost of equity for the Company.

I noted above, I believe that the long-term version of the risk positioning model in more reliable at this time. Focusing on the middle values in Table 3 for the results from the long-term risk positioning model (ECAPM with $\alpha = 0.5$), the average ATWACC is 8.1 percent for the full sample and 7.9 percent for the sub-sample, with corresponding costs of equity estimates of 12.8 percent and 12.5 percent respectively, but I believe that if the ongoing changes in the Company's gas supply acquisition process, the potential exit from

the merchant function and the Sales Reconciliation Rider are fully implemented, the Company will be somewhat less risky than the sample on average.

Considering all of the evidence from both models, the best point estimate for the cost of equity for DEO is 12 percent. This result is about ½ percent lower than the average risk positioning results from the long-term model estimates for the sub-sample, but about 1⅓ percent higher than the multistage DCF estimates. Although I believe the DCF results to be less reliable at this time, I give some weight to the estimates in evaluating the results of the risk positioning. However, it is more correct to say that the estimates from the sample provide a range of values from a low of 11½ percent to a high of 12½ percent. As previously noted, in estimating the cost of equity I round to the nearest ¼ percent (25 basis points) because I do not believe that cost of capital estimates can be made more precisely than that.

Q62. Does this conclude your testimony?

A62. Yes

APPENDIX A

RESUMÉ

MICHAEL J. VILBERT **PRINCIPAL**

Michael Vilbert is an expert in cost of capital, financial planning and valuation who has advised clients on these matters in the context of a wide variety of investment and regulatory decisions. He received his Ph.D. in Financial Economics from the Wharton School of the University of Pennsylvania, an MBA from the University of Utah, an M.S. from the Fletcher School of Law and Diplomacy, Tufts University, and a B.S. degree from the United States Air Force Academy. He joined The Brattle Group in 1994 after a career as an Air Force officer, where he served as a fighter pilot, intelligence officer, and professor of finance at the Air Force Academy.

REPRESENTATIVE CONSULTING EXPERIENCE

- In a securities fraud case, Dr. Vilbert designed and created a model to value the private placement stock of a drug store chain as if there had been full disclosure of the actual financial condition of the firm. He analyzed key financial data and security analyst's reports regarding the future of the industry in order to recreate pro forma balance sheet and income statements under a variety of scenarios designed to establish the value of the firm.

- For pharmaceutical companies rebutting price-fixing claims in antitrust litigation, Dr. Vilbert was a member of a team which prepared a comprehensive analysis of industry profitability. The analysis replicated, tested and critiqued the major recent analyses of drug costs, risks and returns. The analyses helped develop expert witness testimony to rebut allegations of excess profits.

- For an independent electric power producer, Dr. Vilbert created a model that analyzed the reasonableness of rates and costs filed by a natural gas pipeline. The model not only duplicated the pipeline's rates, but it also allowed simulation of a variety of "what if" scenarios associated with cost recovery under alternative time patterns and joint cost allocations. Results of the analysis were adopted by the intervenor group for negotiation with the pipeline.

- For the CFO of an electric utility, Dr. Vilbert developed the valuation model used to support a stranded cost estimation filing. The case involved a conflict between two utilities over the responsibility for out-of-market costs associated with a power purchase contract between them. In addition, he advised and analyzed cost recovery mechanisms

that would allow full recovery of the stranded costs while providing a rate reduction for the company's rate payers.

- Dr. Vilbert has testified as well as assisted in the preparation of testimony and the development of estimation models in numerous cost of capital cases for natural gas pipeline, water utility and electric utility clients before the Federal Energy Regulatory Commission ("FERC") and state regulatory commissions. These have spanned standard estimation techniques (e.g., Discounted Cash Flow and Risk Positioning models). He has also developed and applied more advanced models specific to the industries or lines of business in question, e.g., based on the structure and risk characteristics of cash flows, or based on multi-factor models that better characterize regulated industries.

- Dr. Vilbert has valued several large, residual oil-fired generating stations to evaluate the possible conversion to natural gas or other fuels. In these analyses, the expected pre- and post-conversion station values were computed using a range of market electricity and fuel cost conditions.

- For a major western electric utility, Dr. Vilbert helped prepare testimony that analyzed the prudence of QF contract enforcement. The testimony demonstrated that the utility had not been compensated in its allowed cost of capital for major disallowances stemming from QF contract management.

- Dr. Vilbert analyzed the economic need for a major natural gas pipeline expansion to the Midwest. This involved evaluating forecasts of natural gas use in various regions of the United States and the effect of additional supplies on the pattern of natural gas pipeline use. The analysis was used to justify the expansion before the FERC and the National Energy Board of Canada.

- For a Public Utility Commission in the Northeast, Dr. Vilbert analyzed the auction of an electric utilities purchase power agreements to determine whether the outcome of the auction was in the ratepayers' interest. The work involved the analysis of the auction procedures as well as the benefits to ratepayers of transferring risk of the PPA payments to the buyer.

- Dr. Vilbert led a team tasked to determine whether bridge tolls were "just and reasonable" for a non-profit port authority. Determination of the cost of service for the authority required estimation of the value of the authority's assets using the trended original cost methodology as well as evaluation of the operations and maintenance budgets. Investment costs, bridge traffic information and inflation indices covering a 75 year period were utilized to estimate the value of four bridges and a passenger transit line valued in excess of $1 billion.

- Dr. Vilbert helped a recently privatized railroad in Brazil develop an estimate of its revenue requirements, including a determination of the railroad's cost of capital. He also helped evaluate alternative rate structures designed to provide economic incentives to shippers as well as to the railroad for improved service. This involved the explanation

and analysis of the contribution margin of numerous shipper products, improved cost analysis and evaluation of bottlenecks in the system.

- For a utility in the Southeast, Dr. Vilbert quantified the company's stranded costs under several legislative electric restructuring scenarios. This involved the evaluation of all of the company's fossil and nuclear generating units, its contracts with Qualifying Facilities and the prudence of those QF contracts. He provided analysis concerning the impact of securitizing the company's stranded costs as a means of reducing the cost to the rate payers and several alternative designs for recovering stranded costs.

- For a recently privatized electric utility in Australia, Dr. Vilbert evaluated the proposed regulatory scheme of the Australian Competition and Consumer Commission for the company's electric transmission system. The evaluation highlighted the elements of the proposed regulation which would impose uncompensated asymmetric risks on the company and the need to either eliminate the asymmetry in risk or provide additional compensation so that the company could expect to earn its cost of capital.

- For an electric utility in the Southwest, Dr. Vilbert helped design and create a model to estimate the stranded costs of the company's portfolio of Qualifying Facilities and Power Purchase contracts. This exercise was complicated by the many variations in the provisions of the contracts that required modeling in order to capture the effect of changes in either the performance of the plants or in the estimated market price of electricity.

- Dr. Vilbert helped prepare the testimony responding to a FERC request for further comments on the appropriate return on equity for electric transmission facilities. In addition, Dr. Vilbert was a member of the team that made a presentation to the FERC staff on the expected risks of the unbundled electric transmission line of business.

- Dr. Vilbert and Mr. Frank C. Graves, also of The Brattle Group, prepared testimony evaluating an innovative Canadian stranded cost recovery procedure involving the auctioning of the output of the province's electric generation plants instead of the plants themselves. The evaluation required the analysis of the terms and conditions of the long-term contracts specifying the revenue requirements of the plants for their entire forecasted remaining economic life and required an estimate of the cost of capital for the plant owners under this new stranded cost recovery concept.

- Dr. Vilbert served as the neutral arbitrator for the valuation of a petroleum products tanker. The valuation required analysis of the Jones Act tanker market and the supply and demand balance of the available U.S. constructed tanker fleet.

TESTIMONY

Direct and rebuttal testimony before the Alberta Energy and Utilities Board on behalf of TransAlta Utilities Corporation in the matter of an application for approval of its 1999 and 2000 generation tariff, transmission tariff, and distribution revenue requirement, October 1998.

Direct testimony before the Federal Energy Regulatory Commission on behalf of Central Maine Power in Docket No. ER00-982-000, December 1999.

Direct testimony before the Alberta Energy and Utilities Board on behalf of TransAlta Utilities Corporation for approval of its 2001 transmission tariff, May 2000.

Direct testimony before the Federal Energy Regulatory Commission on behalf of Mississippi River Transmission Corporation in Docket No. RP01-292-000, March 2001.

Written evidence, rebuttal, reply and further reply before the National Energy Board in the matter of an application by TransCanada PipeLines Limited for orders pursuant to Part I and Part IV of the *National Energy Board Act*, Order AO-1-RH-4-2001, May 2001, Nov. 2001, Feb. 2002.

Written evidence before the Public Utility Board on behalf of Newfoundland & Labrador Hydro - Rate Hearings, October 2001.

Direct testimony (with Bill Lindsay) before the Federal Energy Regulatory Commission on behalf of DTE East China, LLC in Docket No. ER02-1599-000, April 2002.

Direct and rebuttal reports before the Arbitration Panel in the arbitration of stranded costs for the City of Casselberry, FL, Case No. 00-CA-1107-16-L, July 2002.

Direct reports before the Arbitration Board for Petroleum products trade in the Arbitration of the Military Sealift Command vs. Household Commercial Financial Services, fair value of sale of the Darnell, October 2002.

Direct testimony and hearing before the Arbitration Panel in the arbitration of stranded costs for the City of Winter Park, FL, In the Circuit Court of the Ninth Judicial Circuit in and for Orange County, FL, Case No. C1-01-4558-39, December 2002.

Direct testimony before the Federal Energy Regulatory Commission on behalf of Florida Power Corporation, dba Progress Energy Florida, Inc. in Docket No. SC03-___-000, March 2003.

Direct report before the Arbitration Panel in the arbitration of stranded costs for the Town of Belleair, FL, Case No. 000-6487-C1-007, April 2003.

Direct and rebuttal reports before the Alberta Energy and Utilities Board in the matter of the Alberta Energy and Utilities Board Act, R.S.A. 2000, c. A-17, and the Regulations under it; in the matter of the Gas Utilities Act, R.S.A. 2000, c. G-5, and the Regulations under it; in the matter of the Public utilities Board Act, R.S.A. 2000, c. P-45, as amended, and the Regulations

under it; and in the matter of Alberta Energy and Utilities Generic Cost of Capital Hearing, Proceeding No. 1271597, July 2003, November 2003.

Written evidence before the National Energy Board in the matter of the National Energy Board Act, R.S.C. 1985, c. N–7, as amended, (Act) and the Regulations made under it; and in the matter of an application by TransCanada PipeLines Limited for orders pursuant to Part IV of the *National Energy Board Act*, for approval of Mainline Tolls for 2004, RH-2-2004, January 2004.

Direct and rebuttal testimony before the Public Service Commission of West Virginia, on Cost of Capital for West Virginia-American Water Company, Case No 04-0373-W-42T, May 2004.

Direct and rebuttal testimony before the Federal Energy Regulatory Commission, on Energy Allocation of Debt Cost for Incremental Shipping Rates for Edison Mission Energy, Docket No. RP04-274-000, December 2004 and March 2005.

Direct testimony before the Arizona Corporation Commission, Cost of Capital for Paradise Valley Water Company, a subsidiary of Arizona-American Water Company, Docket No. WS-01303A-05, May 2005.

Written evidence before the Ontario Energy Board, Cost of Capital for Union Gas Limited, Inc., Docket No. EB-2005-0520, January 2006.

Direct and rebuttal testimony before the Pennsylvania Public Utility Commission, Return on Equity for Metropolitan Edison Company, Docket No. R-00061366 and Pennsylvania Electric Company, Docket No. R-00061367, April 2006 and August 2006.

Expert report in the United States Tax Court, Docket No. 21309-05, 34th Street Partners, DH Petersburg Investment, LLC and Mid-Atlantic Finance, Partners Other than the Tax Matters Partner, Petitioner, v. Commissioner of Internal Revenue, Respondent, July 28, 2006.

Direct and supplemental testimony before the Federal Energy Regulatory Commission, Docket No. ER06-427-003, on behalf of Mystic Development, LLC on the Cost of Capital for Mystic 8 and 9 Generating Plants Operating Under an Reliability Must Run Contract, August 2006 and September 2006.

Direct testimony before the Federal Energy Regulatory Commission, Docket No. ER07-46-000, on behalf of Northwestern Corporation on the Cost of Capital for Transmission Assets, October 2006.

Direct and rebuttal testimony before the Tennessee Regulatory Authority, Case No. 06-00290, on behalf of Tennessee American Water Company, on the Cost of Capital, November, 2006 and April 2007.

Direct testimony before the Public Service Commission of Wisconsin, Docket No. _____, on behalf of Wisconsin Energy Corporation, on the Cost of Capital for Wisconsin Electric Power Company and Wisconsin Gas LLC, May 2007.

Rebuttal testimony before the California Public Utilities Commission, Docket No. A. 07-01-036-39, on behalf of California-American Water Company, on the Cost of Capital, May 2007.

Direct testimony before the Public Utilities Commission of the State of South Dakota, Docket No. NG-07-013, on behalf of NorthWestern Corporation, on the Cost of Capital for NorthWestern Energy Company's natural gas operations in South Dakota, June 2007.

Direct testimony before the Public Utilities Commission of Ohio, Case No. 07-551-EL-AIR, Case No. 07-552-EL-ATA, Case No. 07-553-EL-AAM, and Case No. 07-554-EL-UNC, on behalf of Ohio Edison Company, The Toledo Edison Company, and The Cleveland Electric Illuminating Company, on the cost of capital for the FirstEnergy Company's Ohio electric distribution utilities, June 2007.

Direct testimony before the State Corporation Commission of Virginia on behalf of Virginia Electric and Power Company, on the cost of capital for its southwest coal plant, July 2007.

APPENDIX B

SELECTING THE BENCHMARK SAMPLE AND USE OF MARKET VALUES

I. SAMPLE SELECTION AND THE SAMPLE'S CHARACTERISTICS B-1

II. MARKET VALUE CAPITAL STRUCTURE, COSTS OF DEBT & COSTS OF PREFERRED EQUITY B-4

I. SAMPLE SELECTION AND THE SAMPLE'S CHARACTERISTICS

Q1. How do you select your gas LDC benchmark sample?

A1. To select this sample, I started with the universe of publicly traded natural gas distribution utilities covered by *Value Line Investment Survey Plus*. This resulted in an initial group of 23 companies, to which I added Vectren Corporation because it is often viewed as a natural gas LDC (by Bloomberg, for example). Vectren is involved in both gas and electric distribution activities, but more of its regulated assets are invested in the gas distribution operations.[1] This company is also covered by *Value Line*, but is classified as an Electric Utility due to its regulated electric operations.[2] I then eliminated companies by applying additional selection criteria designed to remove companies with unique circumstances which may bias the cost of capital estimates. The final sample consists of ten gas LDCs, from which I also consider a sub-sample of four companies with the fewest reliability concerns. Table No. MJV-2 reports the estimated range for share of total assets for each company devoted to regulated activities in 2006.

Q2. What are the other selection criteria you applied?

A2. Companies were first eliminated if their operating regions were outside of the continental USA. I then applied my standard selection criteria to narrow the sample to those companies likely to have reliable cost of equity estimates. Specifically, I eliminated all companies whose S&P bond rating as reported by Bloomberg was not investment grade, i.e., less than BBB-, or which were not rated. To guard against measurement bias caused by "thin trading," I also restricted the sample to companies with total operating revenues greater than $300 million (USD) in 2006 as reported by Bloomberg.[3] Companies that

---

[1] The 24 companies are from *Value Line Investment Survey Plus*, reviewed June 11, 2007.

[2] Vectren Utility Holdings, Inc.'s 2006 10-K reveals that about 57 percent of its assets are regulated natural gas distribution assets and 37 percent are regulated electric assets. Because it has a substantial amount of regulated electric activity, I exclude it from the sub-sample of companies I consider to be the most representative of the natural gas distribution line of business and to be most free of characteristics that may bias cost of equity estimates.

[3] Data were reviewed during the second week of June 2007.

had a large merger during the period January 2004 to June 2007 (i.e., just over the past three years) were also generally removed from the sample, although two companies which would otherwise not survive the process were included since their primary M&A activity occurred in 2004. These two companies were Atmos Energy and AGL Resources, and they were subsequently excluded from a sub-sample of cleanest companies I also considered as part of my analysis. The screen for M&A activity was primarily done by scanning each company's news history on Bloomberg and a search of company web pages.[4]

Finally, I required that the companies have historical data available from Bloomberg for the relevant period and had no dividend cuts or restatement of financial statements in the past five years, since the latter can be signs of financial distress.

Q3. Please elaborate on how companies were eliminated from your sample.

A3. Five companies were eliminated immediately because they had a less than investment grade bond rating or no bond rating whatsoever. Three more companies -- Cascade Natural Gas Corp, Keyspan Corp, and Southern Union Co – were eliminated for excessive M&A over the past three years.[5] Nicor Inc. was eliminated because it restated earnings for 1999-2001 and because it settled regulatory compliance issues with the Federal Energy Regulatory Commission ("FERC") in 2003.[6] At the time of the restatement, Nicor's price dropped about 50 percent and issues related to the restatement remained unresolved until recently. UGI Corp. was removed because it primarily sells propane, which is not regulated, and four final companies – Chesapeake Utilities Corp, Energy West Inc, EnergySouth Inc, and RGC Resources Inc – were eliminated for low revenues.

---

[4] Company web pages were searched in December 2003 for M&A activities during the 2001-2003 period, in July 2006 for M&A activities during the period 2004 through July 2006, and in December 2006 for the period August through December 2006.

[5] Keyspan additionally had recent dividend cuts.

[6] Nicor announced on October 29, 2002 that its earnings for 1999-2001 would be revised downwards by $15-35 million. March 4, 2003, Nicor released its restated earnings for 1999-2001 along with 2002 earnings.

Q4. Are there any issues with the remaining companies in your sample?

A4. Perhaps. Several companies in the sample engage in natural gas marketing activities. Given the turmoil of the energy trading markets, the companies' cost of capital estimates may be more volatile than those of more stable companies. Also, although it is characterized as investment grade, Southwest Gas is at the bottom of the scale of investment grade credit ratings and has a relatively low average equity thickness over the past five years – 42 percent compared to over sixty percent for the remaining companies. Closer investigation shows that Southwest Gas's capital structure has been shifting rapidly towards equity over the last five years, with a level of about 50 percent over the most recent two years. These factors suggest a potential reliability problem for estimates of this company's cost of capital at this time. The Laclede Group and South Jersey Industries Inc have lower than average market caps (within the full sample), but with revenues of more than $1.9 billion and $900 million, respectively, they are still large companies. In 2006, Piedmont Natural Gas restated some portions of its 2003-2005 financial reports. Although this can generally lead to less reliable estimates from the equity estimation models, the restatements were not caused by fraudulent activities but were due to an accounting error in the classification of hedging amounts. This type of reclassification would not be expected to change the value of the firm and prices did not show any erratic behavior in the period surrounding the announcement of this reclassification. A potential concern for the DCF estimates is that the industry has experienced a sustained level of M&A activity over the last five years, which has implications discussed in the body of my testimony and in Appendix D for the reliable application of the DCF model. Due to the concerns with the sample, I also report the results for a sub-sample of the gas LDC sample that consists of companies with no material data issues.

Q5. What companies are in the subsample?

A5. The subsample consists of Laclede Group, Northwest Natural Gas, Piedmont Natural Gas, Southwest Gas, and WGL Holdings. Vectren was eliminated because of its mix of both regulated natural gas and regulated electric operations. Atmos Energy and AGL

Resources were eliminated because of concerns about M&A activities in 2004, and South Jersey Industries was eliminated from the sub-sample because of the accounting restatements. All remaining companies fall into the "Regulated" category and as a group have an average S&P business profile lower (i.e., less risky) than Dominion's overall profile.

II. MARKET VALUE CAPITAL STRUCTURE, COSTS OF DEBT & COSTS OF PREFERRED EQUITY

Q6. What capital structure information do you require?

A6. For reasons discussed in my direct testimony and explained in detail in Appendix E, explicit evaluation of the market-value capital structures of the sample companies versus the capital structure used for rate making is vital for a correct interpretation of the market evidence. This requires estimates of the market values of common and preferred equity and debt, and the current market costs of preferred equity and debt.

Q7. How do you calculate the market-value capital structures of the sample companies?

A7. I estimate the capital structure for each company by estimating the market values of common equity, preferred equity and debt from publicly available data. The calculations are in Panels A to J of Table No. MJV-3.

The market value of equity is straightforward: the price per share times the number of shares outstanding. The market value of preferred is set equal to its book value because the portion of the capital structure financed with preferred equity is generally small. The market value of debt is estimated at the book value of debt reported by Bloomberg plus or minus the difference in the estimated fair (market) value and book value of long-term debt as reported in the companies' 10-Ks or annual reports.[7]

[7] See Panels A through J in Table No. MJV-3 for details. The adjustment relies on the difference between the companies' self-reported fair value of long-term debt and the carrying value of the same line items. This information was obtained from the sample companies' annual reports.

For purposes of assessing financial risk to common shareholders, I add an adjustment for short-term debt to the debt portion of the capital structure. This adjustment is used only for those companies whose short-term (current) liabilities exceed their short-term (current) assets. I add an amount equal to the minimum of the difference between short-term liabilities and short-term assets or the amount of short-term debt. The reason for this adjustment is to recognize that when current liabilities exceed current assets, a portion of the companies long-term assets are being financed, in effect, by short-term debt.

The market value capital structure is calculated to be consistent with the time period over which the cost of capital is estimated for the sample. The capital structure is determined over the historical period over which the relevant risk positioning parameters were determined and as of the date analysts provide forward looking growth forecasts. Therefore, Table No. MJV-3 reports the market value capital structure at year end for the years ending 2002 – 2006, and as of the first quarter in 2007. The output of these tables is the market equity-to-value, debt-to-value, and preferred equity-to-value ratios. The overall cost of capital calculation for the risk positioning estimates samples rely on the average of the market value capital structure computed for the years 2002 through 2006 as shown in Table No. MJV-4. The results in columns [1]-[3] are used in the DCF model calculations, while columns [4]-[6] are for the risk positioning models.

Q8. How do you estimate the current market cost of preferred equity?

A8. For companies with preferred equity, the cost of preferred equity for each company was set equal to the yield on an index of preferred stock as reported in the Mergent Bond Record corresponding to the S&P rating of that company's debt. The yields from Mergent were as of May 2007. In general, the average amount of preferred equity in the sample companies' capital structures is very small and frequently zero. No company has more than two percent preferred on average.[8]

[8] Dominion Resources, Inc. holds 0.8 percent preferred equity in its capital structure.

Q9. How do you estimate the current market cost of debt?

A9. The market cost of debt for each company in the DCF analysis is the current yield reported by Bloomberg for a public utility company bond corresponding to the sample company's current debt rating as classified by S&P. The risk positioning analysis, on the other hand, uses the current yield of a utility bond that corresponds to the five-year average debt rating of each company so as to match consistently the horizon of information used by *Value Line* to estimate company betas. The current S&P debt ratings were obtained from Bloomberg.

Bloomberg reports that as of June 11, 2007, the average yield on A-rated Public Utility bonds was 6.23 percent, and 6.43 percent on average for BBB-rated Public Utility bonds.[9] (See Panel C of Workpaper #1 to Table No. MJV-11 for the yields on utility bonds and preferred stock by credit rating.) As discussed in the main body of the Testimony, calculation of the after-tax cost of debt uses the projected marginal tax rate of 35 percent.

[9] All companies in the sample are either BBB, AA, or A. The yield on AA-rated utility bonds is calculated as the yield on A-rated utility bonds minus ½ times the spread between the yield on BBB and A rated utility bonds.

APPENDIX C

RISK POSITIONING METHODOLOGY AND EMPIRICAL RESULTS

I. EQUITY RISK PREMIUM METHODOLOGY 1

A. THE BASIC EQUITY RISK PREMIUM MODEL 1

C. COST OF CAPITAL ESTIMATES 17

Q1. What is the purpose of this appendix?

A1. This appendix reviews the principles behind the risk positioning methodologies, describes the estimation of the parameters used in the models, and details the cost of capital estimates obtained from these methodologies. This appendix intentionally repeats portions of my direct testimony, because I want the reader to be able to have a full discussion of the issues addressed here, rather than having to continually turn back to the corresponding section of the testimony.

I. EQUITY RISK PREMIUM METHODOLOGY

Q2. How is this section of the appendix organized?

A2. It first reviews the basic nature of the equity risk premium approach. It then discusses the individual components of the model: the benchmark risk premium, the relative risk of the company or line of business in question, the appropriate interest rate, and the combination of these elements in a particular equity risk premium model.

A. THE BASIC EQUITY RISK PREMIUM MODEL

Q3. How does the equity risk premium model work?

A3. The equity risk premium approach estimates the cost of equity as the sum of a current interest rate and a risk premium. (It therefore is sometimes also known as the "risk premium" or the "risk positioning" approach.)

This approach may sometimes be applied informally. For example, an analyst or a commission may check the spread between interest rates and what is believed to be a reasonable estimate of the cost of capital at one time, and then apply that spread to changed interest rates to get a new estimate of the cost of capital at another time.

More formal applications of equity risk premium method implement the second approach to cost of capital estimation. They use information on all securities to identify the security market line (Figure 1 in the body of the testimony) and derive the cost of capital

for the individual security based on that security's relative risk. This equity risk premium approach is widely used and underlies most of the current scholarly research on the nature, determinants and magnitude of the cost of capital.

Q4. How are "more formal applications" put into practice?

A4. The essential benchmarks that determine the security market line are the risk-free interest rate and the premium that a security of average risk commands over the risk-free rate. This premium is commonly referred to as the "market risk premium" ("MRP"), i.e., the excess of the expected return on the average common stock over the risk-free interest rate. In the equity risk premium approach the risk-free interest rate and MRP are common to all securities. A security-specific measure of relative risk (beta) is estimated separately and combined with the MRP to obtain the company-specific risk premium.

In principle, there may be more than one factor affecting the expected stock return, each with its own security-specific measure of relative risk and its own benchmark risk premium. For example, the "arbitrage pricing theory" and other "multi-factor" models have been proposed in the academic literature. These models estimate the cost of capital as the sum of a risk-free rate and several security-specific risk premia. However, none of these alternative models has emerged in practice as "the" improvement to use instead of the original, single-factor model. I use the traditional single-factor model in this testimony.

Accordingly, the required elements in my formal equity risk premium approach are the market risk premium, an objective measure of relative risk, the risk-free rate that corresponds to the measure of the market risk premium, and a specific method to combine these elements into an estimate of the cost of capital.

B. MARKET RISK PREMIUM

Q5. Why is a risk premium necessary?

A5. Experience (e.g., the U.S. market's October Crash of 1987) demonstrates that shareholders, even well diversified shareholders, are exposed to enormous risks. By investing in stocks instead of risk-free Government bills, investors subject themselves not only to the risk of earning a return well below those they expected in any year but also to the risk that they might lose much of their initial capital. This is why investors demand a risk premium.

I estimate two versions of the Capital Asset Pricing Model ("CAPM"). The first version measures the market risk premium as the risk premium of average risk common stocks over the long-term risk-free rate. The second version measures the risk premium relative to a short-term risk-free rate, which is the usual measure of the "market risk premium" used in capital market theories.

Q6. Please discuss some of the issues involved in selecting the appropriate MRP?

A6. To determine the cost of capital in a regulatory proceeding, the MRP should be used with a forecast of the same interest rate used to calculate the MRP (i.e., the short-term Treasury bill rate or the long-term Government rate). For example, it would be inconsistent to utilize a short-term risk-free with an estimate of the MRP derived from comparisons to long-term interest rates. In addition, the appropriate measure of the MRP should be based upon the arithmetic mean not the geometric mean return.[1] The arithmetic mean is the simple average while the geometric mean is the compound rate of return between two periods.

Q7. How do you estimate the MRP?

A7. There is presently little consensus on "best practice" for estimating the MRP, which does not mean that each approach is equally valid. For example, the latest edition of the

[1] See, for example, Morningstar, Stocks, Bonds, Bills, and Inflation: Valuation Edition 2007 Yearbook, pp. 75-77.

leading graduate textbook in corporate finance, after recommending use of the arithmetic average realized excess return on the market for many years (which for a while was noticeably over 9 percent), now reviews the current state of the research and expresses the view that the a range between 5 to 8 percent is reasonable for the U.S.[2,3]

My written testimony considers both the historical evidence and the results of scholarly studies of the factors that affect the risk premium for average-risk stocks in order to estimate the benchmark risk premium investors currently expect. I consider the historical difference in returns between the Standard and Poor's 500 Index ("S&P 500") and the risk-free rate, recent academic literature on the MRP and the results of recent surveys to estimate the market risk premium.

Q8. Please summarize the recent literature on the MRP and the conclusions you draw from it?

A8. Some recent research based upon U.S. data challenges the conventional wisdom of using the arithmetic average historical excess returns to estimate the MRP. However, after reviewing the issues in the debate, I remain skeptical for several reasons that the market risk premium has declined in the U.S. as much as is claimed in some of the literature.

First, despite eye-catching claims like "equity risk premium as low as three percent,"[4] and "the death of the risk premium,"[5] not all recent research arrives at the same conclusion. In his presidential address to the American Finance Association in 2001, Professor Constantinides seeks to estimate the unconditional equity premium based on

---

[2] Richard A. Brealey, Stewart C. Myers, and Franklin Allen, *Principles of Corporate Finance*, McGraw-Hill, 8th edition, 2006, pp. 151-154.

[3] In past editions, the authors expressed the view that they are "most comfortable" with values toward the upper end of that range, but this language does not appear in the 8th edition. Although Professor Myers still holds this view, this language and other sections were dropped to accommodate a request to reduce the length of the text.

average historical stock returns.[6] (Note that this address was based upon evidence just before the major fall in market value.) He adjusts the average returns downward by the change in price-earnings ratio because he assumes no change in valuations in an unconditional state. His estimates for 1926 to 2000 and 1951 to 2000 are 8.0 percent and 6.0 percent, respectively, over the 3-month T-bill rate. In another published study in 2001, Professors Harris and Marston use the DCF method to estimate the market risk premium for the U.S. stocks.[7] Using analysts' forecasts to proxy for investors' expectation, they conclude that over the period 1982-1998 the MRP over the *long-term* risk-free rate is 7.14 percent. As yet another example, the paper by Drs. Ibbotson and Chen (2003) adopts a supply side approach to estimate the forward looking long-term sustainable equity returns and equity risk premium based upon economic fundamentals. Their equity risk premium over the *long-term* risk-free rate is estimated to be 3.97 percent in geometric terms and 5.90 percent on an arithmetic basis. They conclude their paper by stating that their estimate of the equity risk premium is "far closer to the historical premium than being zero or negative."[8]

Second, Professor Ivo Welch surveyed a large group of financial economists in 1998 and 1999. The average of the estimated MRP was 7.1 percent in Prof. Welch's first survey and 6.7 percent in his second survey which was based on a smaller number of individuals. However, a more recent survey[9] by Prof. Welch reported only a 5.5 percent MRP.[10] In characterizing these results Prof. Welch notes that "[T]he equity premium consensus

forecast of finance and economics professors seems to have dropped during the last 2 to 3 years, a period with low realized equity premia."[11]

The above quotation from Prof. Welch emphasizes the caution that must attend survey data even from knowledgeable survey participants: the outcome is likely to change quickly with changing market circumstances. Regulatory commissions should not, in my opinion, attempt to keep pace with such rapidly changing opinions.

Third, some of the evidence for negative or close to zero market risk premium simply does not make sense. Despite the relatively high valuation levels, stock returns remain much more volatile than Treasury bond returns. I am not aware of any empirical or theoretical evidence showing that investors would rationally hold equities and not expect to earn a positive risk premium for bearing their higher risk.

Fourth, I am unaware of a convincing theory for why the future MRP should have substantially declined. At the height of the stock market bubble in the U.S., many claimed that the only way to justify the high stock prices would be if the MRP had declined dramatically,[12] but this argument was heard less frequently after the market declined substantially from its tech bubble high. All else equal, a high valuation ratio such as price-earnings ratio implies a low required rate of return, hence a low MRP. However, there is considerable debate about whether the high level of stock prices (despite the burst of the internet bubble from its high in the summer of 2000) represents the transition to a new economy or is simply an "irrational exuberance," which cannot be sustained for the long term. If the former case is true, then the MRP may have decreased permanently. Conversely, the long-run MRP may remain the same even if expected market returns in the short-term are smaller.

[11] *Ibid*, p. 8.

[12] See Robert D. Arnott and Peter L. Bernstein, "What Risk Premium is 'Normal'?," *Financial Analysts Journal* 58:64-85, for an example.

Another common argument for a lower expected MRP is that the U.S. experienced very remarkable growth in the 20th century that was not anticipated at the start of the century. As a result, the average realized excess return is overestimated meaning the standard method of estimating the MRP would be biased upward. However, one recent study by Profs. Jorion and Goetzmann finds, under some simplifying assumptions, that the so-called "survivorship bias" is only 29 basis points.[13] Furthermore, "[I]f investors have overestimated the equity premium over the second half of the last century, Constantinides (2002) argues that 'we now have a bigger puzzle on our hands' Why have investors systematically biased their estimates over such a long horizon?"[14]

To sum up the above, I cite two passages from Profs. Mehra and Prescott's review of the theoretical literature on equity premium puzzle:[15]

> Even if the conditional equity premium given current market conditions is small, and there appears to be general consensus that it is, this in itself does not imply that it was obvious either that the historical premium was too high or that the equity premium has diminished.
>
> In the absence of this [knowledge of the future], and based on what we currently know, we can make the following claim: over the long horizon the equity premium is likely to be similar to what it has been in the past and the returns to investment in equity will continue to substantially dominate that in T-bills for investors with a long planning horizon.

Q9. Is there other scholarly support for the conclusion?

A9. Yes. Another line of research was pursued by Steven N. Kaplan and Richard S. Ruback. They estimate the market risk premium in their article, "The Valuation of Cash Flow

---

[13] Jorion, P., and W. Goetzmann (1999), "Global Stock Markets in the Twentieth Century," *Journal of Finance* 54:953-980. Dimson, Marsh, and Staunton (2003) make a similar point when they comment on the equity risk premia for 16 countries based on returns between 1900 and 2001: "While the United States and the United Kingdom have indeed performed well, compared to other markets there is no indication that they are hugely out of line." p.4.

[14] Mehra, R., and E.C. Prescott (2003), "The Equity Premium in Retrospect," in *Handbook of the Economics of Finance*, Edited by G.M. Constantinides, M. Harris and R. Stulz, Elsevier B.V, p. 926

[15] *Ibid*, p. 926.

Forecasts: An Empirical Analysis."[16] Professors Kaplan and Ruback compare published cash flow forecasts for management buyouts and leveraged recapitalization over the 1983 to 1989 period against the actual market values that resulted from these transactions. One of their results is an estimate of the market risk premium over the long-term Treasury bond yield that is based on careful analysis of actual major investment decisions, not realized market returns. Their median estimate is 7.78 percent and their mean estimate is 7.97 percent.[17] This is considerably higher than my estimate of 6.5 percent. Even if the maturity premium of Treasury bonds over Treasury bills were only 1 percent, well below the best estimate of 1.5 percent the resulting estimate of the market risk premium over Treasury bills is higher than my estimate of 8.0 percent.

Q10. In addition to the scholarly articles and survey evidence you discussed in Section I of your Direct Testimony, what other evidence do you consider to estimate the MRP?

A10. I also consider the long-run realized equity premia reported in Morningstar *SBBI Valuation Edition 2007 Yearbook*. The data provided cover the period 1926 through 2006. The results are discussed below.

Q11. What is the "long-run realized risk premium" in the U.S.?

A11. From 1926 to 2006, the full period reported, Morningstar's data show that the average premium of stocks over Treasury bills is 8.6 percent. I also examine the "post-War" period. The risk premium for 1947-2006 is 8.4 percent.[18] (I exclude 1946 because its economic statistics are heavily influenced by the War years; e.g., the end of price controls yielded an inflation rate of 18 percent. It is not really a "post-War" year, from an economic viewpoint.) These averages often change slightly when another year of data is added to the Ibbotson series. The average premium of stocks over the income returns on

[16] *Journal of Finance*, 50, September 1995, pp. 1059-1093.

[17] *Ibid*, p. 1082.

[18] Morningstar, SBBI Valuation Edition 2007 Yearbook, Appendix A.

long-term Government bonds is 7.1 percent for the 1926 to 2006 period and 7.1 for the 1947 to 2006 period.

Recently there has been a great deal of academic research on the MRP. This research has put practitioners in a dilemma: there is nothing close to a consensus about how the MRP should be estimated, but a general agreement in the academic community seems to be emerging that the old approach of using the average realized return over long periods gives too high an answer.

Q12. What is your conclusion regarding the MRP?

A12. Estimation of the MRP remains controversial. There is no consensus on its value or even how to estimate it. Given a careful review of all of the information, I estimate the risk premium for average risk stocks to be 8.0 percent over Treasury bills and 6.5 percent over long-term Government bonds.

C. RELATIVE RISK

Q13. How do you measure relative risk?

A13. The risk measure I examine is the "beta" of the stocks in question. Beta is a measure of the "systematic" risk of a stock — the extent to which a stock's value fluctuates more or less than average when the market fluctuates. It is the most commonly used measure of risk in capital market theories.

Q14. Please explain beta in more detail.

A14. The basic idea behind beta is that risks that cannot be diversified away in large portfolios matter more than those that can be eliminated by diversification. Beta is a measure of the risks that *cannot* be eliminated by diversification.

Diversification is a vital concept in the study of risk and return. (Harry Markowitz won a Nobel Prize for work showing just how important it was.) Over the long run, the rate of return on the stock market has a very high standard deviation, on the order of 15 - 20 percent per year. But many individual stocks have much higher standard deviations than

this. The stock market's standard deviation is "only" about 15 - 20 percent because when stocks are combined into portfolios, some of the risk of individual stocks is eliminated by diversification. Some stocks go up when others go down, and the average portfolio return — positive or negative — is usually less extreme than that of individual stocks within it.

In the limiting case, if the returns on individual stocks were completely uncorrelated with one another, the formation of a large portfolio of such stocks would eliminate risk entirely. That is, the market's long-run standard deviation would be not 15-20 percent per year, but virtually zero.

The fact that the market's actual annual standard deviation is so large means that, in practice, the returns on stocks are correlated with one another, and to a material degree. The reason is that many factors that make a particular stock go up or down also affect other stocks. Examples include the state of the economy, the balance of trade, and inflation. Thus some risk is "non-diversifiable". Single-factor equity risk premium models derive conditions in which all of these factors can be considered simultaneously, through their impact on the market portfolio. Other models derive somewhat less restrictive conditions under which several of them might be individually relevant.

Again, the basic idea behind all of these models is that risks that cannot be diversified away in large portfolios matter more than those that can be eliminated by diversification, because there are a large number of large portfolios whose managers actively seek the best risk-reward tradeoffs available. Of course, undiversified investors would like to get a premium for bearing diversifiable risk, but they cannot.

Q15. Why not?

A15. Well-diversified investors compete away any premium rates of return for diversifiable risk. Suppose a stock were priced especially low because it had especially high diversifiable risk. Then it would seem to be a bargain to well diversified investors. For example, suppose an industry is subject to active competition, so there is a large risk of

loss of market share. Investors who held a portfolio of all companies in the industry would be immune to this risk, because the loss on one company's stock would be offset by a gain on another's stock. (Of course, the competition might make the whole industry more vulnerable to the business cycle, but the issue here is the diversifiable risk of shifts in market share among firms.)

If the shares were priced especially low because of the risk of a shift in market shares, investors who could hold shares of the whole industry would snap them up. Their buying would drive up the stocks' prices until the premium rates of return for diversifiable risk were eliminated. Since all investors pay the same price, even those who are not diversified can expect no premium for bearing diversifiable risk.

Of course, substantial non–diversifiable risk remains, as the October Crash of 1987 demonstrates. Even an investor who held a portfolio of all traded stocks could not diversify against that type of risk. Sensitivity to such market–wide movements is what beta measures. That type of sensitivity, whether considered in a single- or multi-factor model, determines the risk premium in the cost of equity.

Q16. What does a particular value of beta signify?

A16. By definition, a stock with a beta equal to 1.0 has average non-diversifiable risk: it goes up or down by 10 percent on average when the market goes up or down by 10 percent. Stocks with betas above 1.0 exaggerate the swings in the market: stocks with betas of 2.0 tend to fall 20 percent when the market falls 10 percent, for example. Stocks with betas below 1.0 are less volatile than the market. A stock with a beta of 0.5 will tend to rise 5 percent when the market rises 10 percent.

Q17. How is beta measured?

A17. The usual approach to calculating beta is a statistical comparison of the sensitivity of a stock's (or a portfolio's) return to the market's return. Many investment services report betas, including Merrill Lynch's quarterly Security Risk Evaluation, Bloomberg and the *Value Line Investment Survey*. Betas are not always calculated the same way, and

therefore must be used with a degree of caution, but the basic point that a high beta indicates a risky stock has long been widely accepted by both financial theorists and investment professionals.

Q18. Are there circumstances when the "usual approach to calculating beta" should not be used?

A18. There are at least two cases where the standard estimate of beta should be viewed skeptically.

First, companies in serious financial distress seem to "decouple" from their normal sensitivity to the stock market. The stock prices of financially distressed companies tend to change based more on individual news about their particular circumstances than upon overall market movements. Thus, a risky stock could have a low estimated beta if the company was in financial distress. Other circumstances that may cause a company's stock to decouple include an industry restructuring or major changes in a company's supply or output markets.

Second, similar circumstances seem to arise for companies "in play" during a merger or acquisition. Once again, the individual information about the progress of the proposed takeover is so much more important for that stock than day-to-day market fluctuations that, in practice, beta estimates for such companies seem to be too low.

Q19. How reliable is beta as a risk measure?

A19. Scholarly studies have long confirmed the importance of beta for a stock's required rate of return. It is widely regarded as the best single risk measure available. The merits of beta seemed to have been challenged by widely publicized work by Professors Eugene F. Fama and Kenneth R. French.[19] However, despite the early press reports of their work as signifying that "beta is dead," it turns out that beta is still a potentially important

[19] See for example, "The Capital Asset Pricing Model: Theory and Evidence", Eugene F. Fama and Kenneth R. French, *Journal of Economic Perspectives*, Volume 18, Summer 2004, pp. 25-46.

explanatory factor (albeit one of several) in their work. Thus, beta remains alive and well as the best single measure of relative risk.

D. INTEREST RATE FORECAST

Q20. What interest rates do your procedures require?

A20. Modern capital market theories of risk and return use the short-term risk-free rate of return as the starting benchmark. My measures of the MRP incorporate this approach, since they represent the excess of the expected return on the market over the 30-day U.S. Treasury bill rate and over the long-term U.S. Government bond rate. Accordingly, implementation of my procedures requires use of a forecast of the 30-day Treasury bill rate and the long-term Government bond rate.

E. COST OF CAPITAL MODELS

Q21. How do you combine the above components into an estimate of the cost of capital?

A21. By far the most widely used approach to estimation of the cost of capital is the "Capital Asset Pricing Model," and I do calculate CAPM estimates. However, the CAPM is only one equity risk premium approach technique, and I also use another.

Q22. Please start with the CAPM, by describing the model.

A22. As noted above, the modern models of capital market equilibrium express the cost of equity as the sum of a risk-free rate and a risk premium. The CAPM is the longest-standing and most widely used of these theories. The CAPM states that the cost of capital for investment *s* (e.g., a particular common stock) is given by the following equation:

$$k_s = r_f + \beta_s \times MRP \qquad \textbf{(C-1)}$$

where k_s is the cost of capital for investment *s*; r_f is the risk-free rate, β_s is the beta risk measure for the investment *s*; and *MRP* is the market risk premium.

The CAPM relies on the empirical fact that investors price risky securities to offer a higher expected rate of return than safe securities do. It says that the security market line starts at the risk-free interest rate (that is, that the return on a zero-risk security, the y-axis intercept in Figure 1 in the body of my testimony, equals the risk-free interest rate). Further, it says that the risk premium over the risk-free rate equals the product of beta and the risk premium on a value-weighted portfolio of all investments, which by definition has average risk.

Q23. What other equity risk premium approach model do you use?

A23. Empirical research has long shown that the CAPM tends to overstate the actual sensitivity of the cost of capital to beta: low-beta stocks tend to have higher risk premia than predicted by the CAPM and high-beta stocks tend to have lower risk premia than predicted. A number of variations on the original CAPM theory have been proposed to explain this finding. The difference between the CAPM and the type of relationship identified in the empirical studies is depicted in Figure MJV-C1.

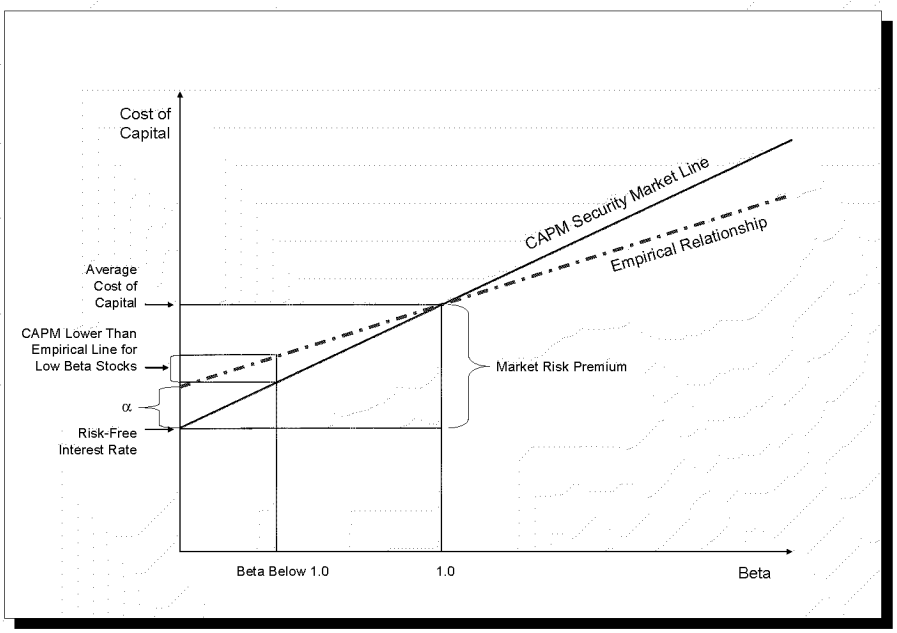

Figure MJV-C1: The Empirical Security Market Line

The second model makes use of these empirical findings. It estimates the cost of capital with the equation,

$$k_s = r_f + \alpha + \beta_s \times (MRP - \alpha) \quad \textbf{(C-2)}$$

where α is the "alpha" of the risk-return line, a constant, and the other symbols are defined as above. I label this model the Empirical Capital Asset Pricing Model, or "ECAPM." For the short-term risk-free rate models, I set alpha equal to 1, 2, and 3 percent which are values somewhat lower than that estimated empirically. For low-beta stocks such as regulated utilities, the use of a lower value for alpha leads to a lower estimate of the cost of capital. For the long-term risk-free rate models, I set alpha equal to both 0.5 percent and 1.5 percent, but I rely more heavily on the 0.5 percent results. The use of a long-term risk-free rate incorporates some of the desired effect of using the ECAPM. That is, the long-term risk-free rate version of the Security Market Line has a higher intercept and a flatter slope than the short-term risk-free version which has been tested. Thus, it is likely that I do not need to make the same degree adjustment when I use the long-term risk-free rate. A summary of the empirical evidence on the magnitude of alpha is provided in Table No. MJV-C1 below.

II. EMPIRICAL EQUITY RISK PREMIUM RESULTS

Q24. How is this part of the appendix organized?

A24. This section presents the full details of my equity risk premium approach analyses, which are summarized in the body of my testimony. Details behind the forecasts of the short-term and the long-term risk-free interest rates are discussed. Next, the beta estimates, and the estimates of the MRP I use in the models are addressed. Finally, this section reports the CAPM and ECAPM results for the sample's costs of equity, and then describes the results of adjusting for differences between the benchmark sample and Dominion's regulated capital structure.

A. RISK-FREE INTEREST RATE FORECAST

Q25. How do you obtain the forecasts of the risk-free interest rates over the period the utility rates set here are to be in effect?

A25. I obtain these forecast rates using data provided by Bloomberg. In particular, I use their reported government debt yields from the "constant maturity series". This information is displayed in Panels A and B of Table No. MJV-9.

Q26. What values do you use for the short-term and long-term risk-free interest rates?

A26. I use a value of 4.1 percent for the short-term risk-free interest rate and a value of 5.1 percent for the long-term risk-free interest rate as the benchmark interest rates in the equity risk premium analyses. These forecasts are constructed by using historical yield curve data to find the long-run average implied term premia on government securities, and combining these with recent yield curve data. Details of their calculation can be found in the Workpapers to Table No. MJV-9.

B. BETAS AND THE MARKET RISK PREMIUM

1. Beta Estimation Procedures

Q27. How do you estimate beta?

A27. I use the beta estimates reported in the *Value Line* for the sample companies. The current *Value Line* beta estimates range from 0.70 to 0.95 for the benchmark sample (See Workpaper #1 to Table No. MJV-10).

2. Market Risk Premium Estimation

Q28. Given all of the evidence, what MRP do you use in your analysis?

A28. It is clear that market return information is volatile and difficult to interpret, but based on the collective evidence, the MRP I use for the short-term risk-free rate is 8 percent and for the long-term risk-free rate is 6.5 percent.

C. Cost Of Capital Estimates

Q29. Based on these data, what are the values you calculate for the overall cost of capital and the corresponding cost of equity for the sample?

A29. Panels A and B of Table No. MJV-10 present the cost of equity results using the equity risk positioning methods. Panel A uses the long-term risk-free rate forecast while Panel B uses the short-term risk-free rate forecast. These returns on equity are replicated and the overall cost of capital for the various equity risk positioning methods are reported in Table No. MJV-11, Panels A to G. Panels A through C utilize the long-term risk-free rate while Panels D through G use the short-term risk free rate. Panel A reports the cost of capital estimates using the CAPM results for the long-term risk-free rate, while Panels B and C report these estimates for the ECAPM cost of equity results using ECAPM parameters of 0.5 and 1.5 percent, respectively. Panel D reports the CAPM estimates using the short-term risk free rate, while Panels E, F and G report ECAPM results using ECAPM parameters of 1, 2 and 3 respectively. In each panel, column [8] reports the overall cost of capital for each company. The last row of each panel reports the sample average.

Q30. What does the sample market data imply about the sample's cost of equity at Dominion's proposed 44.8 percent equity ratio?

A30. The sample average ATWACC from each panel of Table No. MJV-11 is reproduced in column [1] of Table No. MJV-12, which then reports the cost of equity for each of the risk positioning methods that is consistent with the sample information and Dominion's proposed capital structure. The sample average ATWACCs and corresponding costs of equity at a 44.8 percent equity ratio are also displayed in Table 3 of my testimony.

I discuss the implications of the equity risk positioning results for the sample in the main body of my testimony.

Table MJV-C1

EMPIRICAL EVIDENCE ON THE ALPHA FACTOR IN ECAPM*

AUTHOR	RANGE OF ALPHA	PERIOD RELIED UPON
Black (1993)[1]	1% for betas 0 to 0.80	1931-1991
Black, Jensen and Scholes (1972)[2]	4.31%	1931-1965
Fama and McBeth (1972)	5.76%	1935-1968
Fama and French (1992)[3]	7.32%	1941-1990
Litzenberger and Ramaswamy (1979)[4]	5.32%	1936-1977
Litzenberger, Ramaswamy and Sosin (1980)	1.63% to 3.91%	1926-1978
Pettengill, Sundaram and Mathur (1995)[5]	4.6%	1936-1990

*The figures reported in this table are for the longest estimation period available and, when applicable, use the authors' recommended estimation technique. Many of the articles cited also estimate alpha for sub-periods and those alphas may vary.

[1]Black estimates alpha in a one step procedure rather than in an un-biased two-step procedure.

[2]Estimate a negative alpha for the subperiod 1931-39 which contain the depression years 1931-33 and 1937-39.

[3]Calculated using Ibbotson's data for the 30-day treasury yield.

[4]Relies on Lizenberger and Ramaswamy's before-tax estimation results. Comparable after-tax alpha estimate is 4.4%.

[5]Pettengill, Sundaram and Mathur rely on total returns for the period 1936 through 1990 and use 90-day treasuries. The 4.6% figure is calculated using auction averages 90-day treasuries back to 1941 as no other series were found this far back.

B. CONCLUSIONS ABOUT DCF 8

II. EMPIRICAL DCF RESULTS 8

A. PRELIMINARY MATTERS 9

B. GROWTH RATES 9

C. DIVIDEND AND PRICE INPUTS 12

D. COMPANY-SPECIFIC DCF COST OF CAPITAL ESTIMATES 12

Q1. What is the purpose of this appendix?

A1. This appendix reviews the principles behind the discounted cash flow or "DCF" methodology and the details of the cost of capital estimates obtained from this methodology.

I. DISCOUNTED CASH FLOW METHODOLOGY PRINCIPLES

Q2. How is this section of the appendix organized?

A2. The first part discusses the general principles that underlie the DCF approach. The second portion describes the strengths and weaknesses of the DCF model and why it is generally less reliable for estimating the cost of capital for the sample companies at the present time than the risk positioning method discussed in Appendix C.

A. SIMPLE AND MULTI-STAGE DISCOUNTED CASH FLOW MODELS

Q3. Please summarize the DCF model.

A3. The DCF model takes the first approach to cost of capital estimation discussed with Figure 1 in Section II-A of my direct testimony. That is, it attempts to measure the cost of equity in one step. The method assumes that the market price of a stock is equal to the present value of the dividends that its owners expect to receive. The method also assumes that this present value can be calculated by the standard formula for the present value of a cash flow stream:

$$P = \frac{D_1}{(1+k)} + \frac{D_2}{(1+k)^2} + \frac{D_3}{(1+k)^3} + \cdots + \frac{D_T}{(1+k)^T} \qquad \textbf{(D-1)}$$

where "P" is the market price of the stock; "D_i" is the dividend cash flow expected at the end of period i; "k" is the cost of capital; and "T" is the last period in which a dividend cash flow is to be received. The formula just says that the stock price is equal to the sum of the expected future dividends, each discounted for the time and risk between now and the time the dividend is expected to be received.

Most DCF applications go even further, and make very strong (*i.e.*, unrealistic) assumptions that yield a simplification of the standard formula, which then can be rearranged to estimate the cost of capital. Specifically, if investors expect a dividend stream that will grow forever at a steady rate, the market price of the stock will be given by a very simple formula,

$$P = \frac{D_1}{(k-g)} \qquad \textbf{(D-2)}$$

where "D_1" is the dividend expected at the end of the first period, "g" is the perpetual growth rate, and "P" and "k" are the market price and the cost of capital, as before. Equation D-2 is a simplified version of Equation D-1 that can be solved to yield the well known "DCF formula" for the cost of capital:

$$\begin{aligned} k &= \frac{D_1}{P} + g \\ &= \frac{D_0 \times (1+g)}{P} + g \end{aligned} \qquad \textbf{(D-3)}$$

where "D_0" is the current dividend, which investors expect to increase at rate g by the end of the next period, and the other symbols are defined as before. Equation D-3 says that if Equation D-2 holds, the cost of capital equals the expected dividend yield plus the (perpetual) expected future growth rate of dividends. I refer to this as the simple DCF model. Of course, the "simple" model is simple because it relies on very strong (*i.e.*, very unrealistic) assumptions.

Q4. Are there other versions of the DCF models besides the "simple" one?

A4. Yes. If Equation D-2 and its underlying assumptions do not hold, sometimes other variations of the general present value formula, Equation D-1, can be used to solve for k in ways that differ from Equation D-3. For example, if there is reason to believe that investors do *not* expect a steady growth rate forever, but rather have different growth rate forecasts in the near term (e.g., over the next five or ten years as compared with subsequent periods), these forecasts can be used to specify the early dividends in

Equation D-1. Once the near-term dividends are specified, Equation D-2 can be used to specify the share price value at the end of the near-term (e.g., at the end of five or ten years), and the resulting cash flow stream can be solved for the cost of capital using Equation D-1.

More formally, the "multi-stage" DCF approach solves the following equation for k:

$$P = \frac{D_1}{(1+k)} + \frac{D_2}{(1+k)^2} + \frac{D_3}{(1+k)^3} + \cdots + \frac{D_T + P_{TERM}}{(1+k)^T} \quad \textbf{(D-4)}$$

The terminal price, P_{TERM} is estimated as

$$P_{TERM} = \frac{D_{T+1}}{(k - g_{LR})} \quad \textbf{(D-5)}$$

where T is the last of the periods in which a near term dividend forecast is made and g_{LR} is the long-run growth rate. Thus, Equation D-4 defers adoption of the very strong perpetual growth assumptions that underlie Equation D-2 — and hence the simple DCF formula, Equation D-3 — for as long as possible, and instead relies on near term knowledge to improve the estimate of k. I examine both simple and multi-stage DCF results below.

Q5. What are the merits of the DCF model?

A5. The DCF approach is conceptually sound only if its assumptions are met. In actual practice one can run into difficulty because those assumptions are so strong, and hence so unlikely to correspond to reality. Two conditions are well-known to be necessary for the DCF approach to yield a reliable estimate of the cost of capital: the variant of the present value formula, Equation D-1, that is used must actually match the variations in investor expectations for the dividend growth path; and the growth rate(s) used in that formula must match current investor expectations. Less frequently noted conditions may also create problems.

The DCF model assumes that investors expect the cost of capital to be the same in all future years. Investors may not expect the cost of capital to be the same, which can bias the DCF estimate of the cost of capital in either direction.

The DCF model only works for companies for which the standard present value formula works. The standard formula does *not* work for companies that operate in industries or markets options (*e.g.*, puts and calls on common stocks), and so it will not work for companies whose stocks behave as options do. Option-pricing effects will be important for companies in financial distress, for example, which implies the DCF model will *understate* their cost of capital, all else equal.

In recent years even the most basic DCF assumption, that the market price of a stock in the absence of growth options is given by the standard present value formula (*i.e.*, by Equation D-1 above), has been called into question by a literature on market volatility.[1] In any case, it is still too early to throw out the standard formula, if for no other reasons than that the evidence is still controversial and no one has offered a good replacement. But the evidence suggests that it must be viewed with more caution than financial analysts have traditionally applied. Simple models of stock prices may not be consistent with the available evidence on stock market volatility.

Q6. Normally DCF debates center on the right growth rate. What principles underlie that choice?

A6. Finding the right growth rate(s) is indeed the usual "hard part" of a DCF application. The original approach to estimation of g relied on average historical growth rates in

[1] See for example, Robert J. Shiller (1981), "Do Stock Prices Move Too Much to be Justified by Subsequent Changes in Dividends?," *The American Economic Review*, Vol. 71, No. 3, pp. 421-436. John Y. Campbell and Robert J. Shiller (1988), "The Dividend-Price Ratio and Expectations of Future Dividends and Discount Factors," *The Review of Financial Studies*, Vol. 1, No. 3, pp. 195-228. Lucy F. Ackert and Brian F. Smith (1993), "Stock Price Volatility, Ordinary Dividends, and Other Cash Flows to Shareholders," *Journal of Finance*, Vol. 48, No. 1, pp. 1147-1160. Eugene F. Fama and Kenneth R. French (2001), "Disappearing Dividends: Changing Firm Characteristics or Lower Propensity to Pay?," *Journal of Financial Economics*, Vol. 60, pp. 3-43. Borja Larrain and Motohiro Yogo (2005), "Does Firm Value Move Too Much to be Justified by Subsequent Changes in Cash Flow?," Federal Reserve Bank of Boston, *Working Paper*, No. 05-18.

observable variables, such as dividends or earnings, or on the "sustainable growth" approach, which estimates *g* as the average book rate of return times the fraction of earnings retained within the firm. But it is highly unlikely that historical averages over periods with widely varying rates of inflation, interest rates and costs of capital, such as in the relatively recent past, will equal current growth rate expectations. A better approach is to use the growth rates currently expected by investment analysts, if an adequate sample of such rates is available. If this approach is feasible and if the person estimating the cost of capital is able to select the appropriate version of the DCF formula, the DCF method should yield a reasonable estimate of the cost of capital for companies not in financial distress and without material option-pricing effects (always subject to recent concerns about the applicability of the basic present value formula to stock prices as well as issues of optimism bias). However, for the DCF approach to work, the basic stable-growth assumption must become reasonable and the underlying stable-growth rate must become determinable *within the period for which forecasts are available*.

Most cost of capital experts rely on earnings growth rate forecasts, not dividend growth rates, for several reasons. First, although the model is derived from dividend growth rates, the more fundamental parameter is earnings growth because dividends are paid from earnings. Second, analyst forecasts of dividend growth rates are generally not available, but earnings growth forecasts are. Third, a better approach than relying on historical information is to use the growth rates currently expected by investment analysts, if an adequate sample of such rates is available. Analysts' forecasts are superior to time series forecasts based upon single variable historical data as has been documented and confirmed extensively in academic research.[1] If this approach is feasible and if the person

[1]Lawrence D. Brown and Michael S. Rozeff (1978), "The Superiority of Analysts Forecasts as Measures of Expectations: Evidence from Earnings," *Journal of Finance*, Vol. XXXIII, No. 1, pp. 1-16. J. Cragg and B.G. Malkiel (1982), *Expectations and the Structure of Share Prices*, National Bureau of Economic Research, University of Chicago Press. R.S. Harris (1986), "Using Analysts' Growth Forecasts to Estimate Shareholder Required Rates of Return," *Financial Management*, Spring Issue, pp. 58-67. J. H. Vander Weide and W. T. Carleton (1988), "Investor Growth Expectations: Analysts vs. History," *Journal of Portfolio Management*, Spring, pp. 78-82. T. Lys and S. Sohn (1990), "The Association Between Revisions of Financial Analysts Earnings Forecasts and Security Price Changes," *Journal of Accounting and Economics*, vol 13, pp. 341-363.

estimating the cost of capital is able to select the appropriate version of the DCF formula, the DCF method should yield a reasonable estimate of the cost of capital for companies not in financial distress and without material option-pricing effects. However, for the DCF approach to work, the basic stable-growth assumption must become reasonable and the underlying stable-growth rate must become determinable *within the period for which forecasts are available*.

Q7. What is the so called "optimism bias" in the earnings growth rate forecasts of security analysts and what is its effect on the DCF analysis?

A7. Optimism bias is related to the observed tendency for analysts to forecast earnings growth rates that are higher than are actually achieved. This tendency to over estimate growth rates is perhaps related to incentives faced by analysts that provide rewards not strictly based upon the accuracy of the forecasts. To the extent optimism bias is present in the analysts' earnings forecasts; the cost of capital estimates from the DCF model would be too high.

Q8. Does optimism bias mean that the DCF estimates are completely unreliable?

A8. No. The effect of optimism bias is least likely to affect DCF estimates for large, rate regulated companies in relatively stable segments of an industry. Furthermore, the magnitude of the optimism bias (if any) for regulated companies is not clear. This issue is addressed in a paper by Chan, Karceski, and Lakonishok (2003)[2] who sort companies on the basis of the size of the I/B/E/S forecasts to test the level of optimism bias. Utilities constitute 25 percent of the companies in lowest quintile, and by one measure the level of optimism bias is 4 percent. However, the 4 percent figure does not represent the complete characterization of the results in the paper. Table IX of the paper shows that the median I/B/E/S forecast for the first (lowest) quintile averages 6.0 percent. The realized "Income before Extraordinary Items" is 2.0 percent (implying a four percent

[2] L. K.C. Chan, J. Karceski, and J. Lakonishok, 2003, "The Level and Persistence of Growth Rates," *Journal of Finance* 58(2):643-684.

upward bias in I/B/E/S forecasts), but the "Portfolio Income before Extraordinary Items" is 8.0 percent (implying a two percent downward bias in I/B/E/S forecasts).

The difference between the "Income before Extraordinary Items" and "Portfolio Income before Extraordinary Items" is whether individual firms or a portfolio are used in estimating the realized returns. The first is a simple average of all firms in the quintile while the second is a market value weighted-average. Although both measures of bias have their own drawbacks according to the authors,[3] the Portfolio Income measure gives more weight to the larger firms in the quintile such as regulated utilities. In addition, the paper demonstrates that "analysts' forecasts as well as investors' valuations reflect a wide-spread belief in the investment community that many firms can achieve streaks of high growth in earnings."[4] Therefore, it is not clear how severe the problem of optimism bias may be for regulated utilities or even whether there is a problem at all.

Finally, the two-stage DCF model also adjusts for any over optimistic (or pessimistic) growth rate forecasts by substituting the long-term GDP growth rate for the 5-year growth rate forecasts of the analysts in the years beginning in year 11. I linearly trend the 5-year forecast growth rate to the GDP forecast growth rate in years 6 to 10.

Q9. What about the reforms by the National Associate of Security Dealers (NASD) that were designed to reduce the conflicts of interest and pressures brought against security analysts? Have those reforms been generally successful?

A9. Yes. The conclusion from the Joint Report by NASD and the New York Stock Exchange ("NYSE") on the reforms states

> …the SRO Rules have been effective in helping restore integrity to research by minimizing the influences of investment banking and promoting transparency of other potential conflicts of interest. Evidence

[3] Chan, Karceski, and Lakonishok, *op. cit.*, p. 675.

[4] Chan, Karceski, and Lakonishok, *op. cit.*, p. 663.

> also suggests that investors are benefiting from more balanced and accurate research to aid their investment decisions.[5]

The report does note additional reforms are advisable, but the situation is far different today than during the height of the tech bubble when analyst objectivity was clearly suspect.

B. CONCLUSIONS ABOUT DCF

Q10. Please sum up the implications of this part of the appendix.

A10. The unavoidable questions about the DCF model's strong assumptions — whether the basic present value formula works for stocks, whether option pricing effects are important for the company, whether the right variant of the basic formula has been found, and whether the true growth rate expectations have been identified — cause me to view the DCF method as *inherently* less reliable than equity risk premium approach, the other approach I use. However, because the DCF method has been widely used in the past and in other forums when the industry's economic conditions were different from today's, I submit DCF evidence in this case. DCF estimates also serve as a check on the values provided by the risk positioning approach methods.

II. EMPIRICAL DCF RESULTS

Q11. How is this part of the appendix organized?

A11. This section presents the details of my DCF analyses for the sample, which are summarized in my written testimony. The first part describes some preliminary matters, such as the calculation of market value capital structures of the sample companies and the determination of the growth rates. It then turns to the details of the DCF estimates themselves.

---

[5] Joint Report by NASD and NYSE on the Operation and Effectiveness of the Research Analyst Conflict of Interest Rules, December 2005, p. 44.

In particular, implementation of the simple DCF models described above requires an estimate of the current price, the dividend, and near-term and long-run growth rate forecasts. The simple DCF model relies only on a single growth rate forecast, while the multistage DCF model employs both near-term individual company forecasts and long-run GDP growth rate forecasts. The remaining parts of this section describe each of these inputs in turn.

A. PRELIMINARY MATTERS

Q12. In Appendix C you discuss estimating cost of capital and implied cost of equity using the risk positioning methodology. What, if anything, is different when you use the DCF method?

A12. First, the timing of the market value capital structure calculations is different in the DCF method than in the equity risk premium method. The equity risk premium method relies on the average capital structure over the five-year period *Value Line* uses to estimate beta while the DCF approach uses only current data, so the relevant market value capital structure measure is the most recent that can be calculated. This capital structure is reported in columns [1]-[3] of Table No. MJV-4.

B. GROWTH RATES

Q13. What growth rates do you use?

A13. For reasons discussed above, historical growth rates are generally unreliable as forecasts of current investor expectations. I therefore use rates forecasted by security analysts.

The ideal in a DCF application would be a detailed forecast of future dividends, year by year well into the future, based on a large sample of investment analysts' expectations. I know of no source of such data. Dividends are ultimately paid from earnings, however, and earnings forecasts are available for a few years. Investors do not expect dividends to grow in lockstep with earnings, but for companies for which the DCF approach can be used reliably (*i.e.*, for relatively stable companies whose prices do not include the option-like values described previously), they do expect dividends to track earnings over the

long-run. Thus, use of earnings growth rates as a proxy for expectations of dividend growth rates is a common practice.

Accordingly, the first step in my DCF analysis is to examine a sample of investment analysts' forecasted earnings growth rates. In particular, I utilize Bloomberg's BEst and *Value Line's* forecasted earnings growth.[6] The projected earnings growth rates for the sample companies are in Table No. MJV-5. Column [1] reports Bloomberg's BEst analysts' forecasts of the long-term earnings growth for the sample companies. Column [2] reports the number of analysts that provided a forecast. Columns [3] and [4] report *Value Line's* forecasted earnings per share ("EPS") value for each company for 2007 and 2010-2012 respectively. Column [5] provides *Value Line's* implied long-term growth rate forecast, and column [6] provides a weighted average growth rate for each company across the two sources. (I treat the *Value Line* forecasts as though they overlap exactly with the forecasts from Bloomberg.) These growth rates underlie my simple and multi-stage DCF analyses.

In particular, the five-year average annual growth rate is the perpetual growth rate I employ in the simple DCF model.[7] In the multi-stage model, I rely on the company-specific growth rate until 2012 and on the long-term GDP forecast for year 2018 onwards. During the years from 2013 to 2017, I assume the growth rate converges linearly towards the long-term GDP forecast.[8]

Q14. Do these growth rates correspond to the ideal you mentioned above?

A14. No, not completely. While forecasted growth rates are the quantity required in principle, the forecasts need to go far enough out into the future so that it is reasonable to believe that investors expect a stable growth path afterwards. As can be seen from Table No. MJV-5, the growth rate estimates do not support the view that investors are expecting

---

[6] The BEst growth rates were downloaded from Bloomberg on June 11, 2007. *Value Line* numbers are their most recent available, variously dated June 15, 2007 or June 29, 2007. (See Table No. MJV-5.)

[7] This growth rate is in column [6] of Table No. MJV-5.

[8] I use the long-term U.S. GDP growth estimate from *Blue Chip Economic Indicators* (March 10, 2007).

growth rates equal to the single perpetual growth rate assumed in the simple DCF model. For example, Vectren and WGL Holdings have growth rate estimates of 3.5 percent and 2.7 percent respectively, while South Jersey Industries Inc's estimate is 6.5 percent (see column [6], Table No. MJV-5).

It should be noted that there are at least two analyst estimates for all of the sample companies, though The Laclede Group has only two. The comparison between the average growth rate forecasts and the growth in GDP forecast indicates that these growth rates may be under-stated for some gas companies.

Q15. How well are the conditions needed for DCF reliability met at present?

A15. The requisite conditions for the sample companies are not fully met at this time. Of particular concern for this proceeding is the uncertainty about what investors truly expect the long-run outlook for the sample companies to be. The longest time period available for growth rate forecasts of which I am aware is five years. The long-run growth rate (*i.e.*, the growth rate after the energy industry settles into a steady state, which is certainly *beyond* the next five years for this industry) drives the actual results one gets with the DCF model. Unfortunately, this implies that unless the company or industry in question is stable – so there is little doubt as to the growth rate investors expect – DCF results in practice can end up being driven by the subjective judgment of the analyst who performs the work.

Such circumstances imply that a regulator may often be faced with a wide range of DCF numbers, none of which can be well grounded in objective data on true long-run growth expectations, *because no such objective data now exist*. DCF for firms or industries in flux is *inherently* subjective with regard to a parameter (the long-run growth rate) that drives the answer one gets.

C. DIVIDEND AND PRICE INPUTS

Q16. What values do you use for dividends and stock prices?

A16. Dividends are the last recorded dividend payments as reported by Bloomberg, the 1st-quarter 2007 dividend. This dividend is grown at the estimated growth rate and divided by the price described below to estimate the dividend yield for the simple and multi-stage DCF models.

For the sample calculations, stock prices are the average of the closing stock prices for the 15 trading days (approximately three weeks) ending June 11, 2007 for each company, the same date growth rate estimates were pulled from Bloomberg. I do not use a longer period to measure the price, because that would be inconsistent with the principles that underlie the DCF formula. The DCF approach assumes the stock price is the present value of future expected dividends. Stock prices six months or a year ago reflect expectations at that time, which are different from those that underlie the currently available growth forecasts. At the same time, use of an average over a brief period helps guard against a company's price on a particular day price being unduly influenced by mistaken information, differences in trading frequency, and the like.

The closing stock price is used because it is at least as good as any other measure of the day's outcome, and may be better for DCF purposes. In particular, if there were any single price during the day that would affect investors' decisions to buy or sell a stock, I would suspect that it would be each day's closing price, not the high or low during the day. The daily price changes reported in the financial pages, for example, are from close to close, not from high to high or from low to low.

D. COMPANY-SPECIFIC DCF COST OF CAPITAL ESTIMATES

Q17. What DCF estimates do these data yield?

A17. The cost of equity results for the simple and multistage DCF models are shown in Table No. MJV-6. Panel A reports the results for the simple DCF method while Panel B reports

the results for the multistage DCF method using the long-term GDP growth rate as the perpetual growth rate.

Q18. What overall cost of capital estimates result from the DCF cost of equity estimates?

A18. The capital structure, DCF cost of equity, and cost of debt estimates are combined to obtain the overall after-tax weighted-average cost of capital for each sample company. These results are presented in Table No. MJV-7. Again, Panel A relies on the simple DCF cost of equity results while Panel B relies on the multistage DCF cost of equity results.

Q19. What information do you report in Table No. MJV-8?

A19. This table reports the return on equity consistent with the sample's estimated overall after-tax weighted-average cost of capital and the proposed equity thickness of 44.8 percent for Dominion. For both the simple DCF and multistage DCF methods, the sample's average ATWACC is reported in column [1]. Column [6] reports the return on equity as if the sample companies' average market value capital structure had been that currently proposed by Dominion.

Q20. What are the implications of these results?

A20. The implication of these numbers is discussed in my written testimony, along with the findings of the equity risk premium approach.

APPENDIX E

EFFECT OF DEBT ON THE COST OF EQUITY

I. AN OVERVIEW OF THE ECONOMIC LITERATURE E-1

A. TAX EFFECTS E-1
1. Base Case: No Taxes, No Risk to High Debt Ratios E-2
2. Corporate Tax Deduction for Interest Expense E-3
3. Personal Tax Burden on Interest Expense E-5

B. NON-TAX EFFECTS E-7

II. EXPANDED EXAMPLE E-12

A. DETAILS OF DIFFERENT LEVELS OF DEBT E-12

B. THE IMPACT OF INCOME AND INTEREST E-16

C. THE EFFECT OF TAXES E-19

D. COMBINED EFFECTS E-25

Q1. What is the purpose of this Appendix?

A1. In this appendix, I provide details on the effects of debt on the cost of equity. First, I summarize a fairly large body of financial research on capital structure. Second, I provide an extended example to illustrate the effect of debt on the cost of equity.

I. AN OVERVIEW OF THE ECONOMIC LITERATURE

Q2. What is the focus of the economic literature on the effects of debt?

A2. The economic literature focuses on the effects of debt on the value of a firm. The standard way to recognize one of these effects, the impact of the fact that interest expense is tax-deductible, is to discount the all-equity after-tax operating cash flows generated by a firm or an investment project at a weighted average cost of capital, typically known in textbooks as the "WACC." The textbook WACC equals the *market*-value weighted average of the cost of equity and the *after-tax*, *current* cost of debt. However, rate regulation in North America has a legacy of working with another weighted-average cost of capital, the *book*-value weighted average of the cost of equity and the *before-tax*, *embedded* cost of debt. To distinguish the concepts, I refer to the after-tax weighted-average cost of capital as ATWACC.

Q3. How is this section of the appendix organized?

A3. It starts with the tax effects of debt. It then turns to other effects of debt.

A. TAX EFFECTS

Q4. What are the key findings in the literature regarding tax effects?

A4. Three seminal papers are vital for this literature. The first assumes no taxes and risk-free debt. The second adds corporate income taxes. The third adds personal income taxes.

1. Base Case: No Taxes, No Risk to High Debt Ratios

Q5. Please start by explaining the simplest case of the effect of debt on the value of a firm.

A5. The "base case," no taxes and no costs to excessive debt, was worked out in a classic 1958 paper by Franco Modigliani and Merton Miller, two economists who eventually won Nobel Prizes in part for their body of work on the effects of debt.[1] Their 1958 paper made what is in retrospect a very simple point: if there are no taxes and no risk to the use of excessive debt, use of debt will have no effect on a company's operating cash flows (i.e., the cash flows to investors as a group, debt plus equity combined). If the operating cash flows are the same regardless of whether the company finances mostly with debt or mostly with equity, then the value of the firm cannot be affected at all by the debt ratio. In cost of capital terms, this means the overall cost of capital is constant regardless of the debt ratio, too.

In the base case, issuing debt merely divides the cash flows into two pools, one for bondholders and one for shareholders. If the divided pools have different priorities in claims on the cash flows, the risks and costs of capital will differ for each pool. But the risk and overall cost of capital of the entire firm, the sum of the two pools, is constant regardless of the debt ratio. Thus,

$$r_1^* = r_{A1} \qquad \text{(E-1a)}$$

where r^*_1 is the overall after-tax cost of capital at any particular capital structure and r_{A1} is the all-equity cost of capital for the firm. (The "1" subscripts distinguish the case where there are no taxes from subsequent equations that consider first corporate and then both corporate and personal taxes.) With no taxes and no risk to debt, the overall cost of capital does not change with capital structure.

This implies that the relationship of the overall cost of capital to the component costs of debt and equity is

[1] Franco Modigliani and Merton H. Miller (1958), "The Cost of Capital, Corporation Finance and the Theory of Investment," *American Economic Review*, 48, pp. 261-297.

$$r_{E1} \times \left(\frac{E}{V}\right) + r_{D1} \times \left(\frac{D}{V}\right) = r_1^* \qquad \text{(E-1b)}$$

with the overall cost of capital (r^*) on the *right* side, as the *independent* variable, and the costs of equity (r_E) and debt (r_D) on the left side, as *dependent* variables determined by the overall cost of capital and by the capital structure (i.e., the shares of equity (E) and debt (D) in overall firm value (V=E+D)) that the firm happens to choose. Note that if equation (E-1a) were correct, the equation that solved it for the cost of equity would be,

$$r_{E1} = r_1^* + (r_1^* - r_D) \times \left(\frac{D}{E}\right) \qquad \text{(E-1c)}$$

Note also that (D/E) gets exponentially higher in this equation as the debt-to-value ratio increases[2] i.e., the cost of equity increases exponentially with leverage.

2. Corporate Tax Deduction for Interest Expense

Q6. What happens when you add corporate taxes to the discussion?

A6. If corporate taxes exist with risk-free debt (and if only taxes at the corporate level matter, not taxes at the level of the investor's personal tax return), the initial conclusion changes. Debt at the corporate level reduces the company's tax liability by an amount equal to the marginal tax rate times interest expense. All else equal, this will add value to the company because more of the operating cash flows will end up in the hands of investors as a group. That is, if only corporate taxes mattered, interest would add cash to the firm equal to the corporate tax rate times the interest expense. This increase in cash would increase the value of the firm, all else equal. In cost of capital terms, it would reduce the overall cost of capital.

How much the value of the firm would rise and *how far* the overall cost of capital would fall would depend in part on how often the company adjusts its capital structure, but this

[2] For example, at 20-80, 50-50, and 80-20 debt-equity ratios, (D/E) equals, respectively, (20/80) = 0.25, (50/50) = 1.0, and (80/20) = 4.0. The extra 30 percent of debt going from 20-80 to 50-50 has much less impact on (D/E) [i.e., by moving it from 0.25 to 1.0] than the extra 30 percent of debt going from 50-50 to 80-20 [i.e., by moving it from 1.0 to 4.0]. Since the cost of equity equals a constant risk premium times the debt-equity ratio, the cost of equity grows ever more rapidly as you add more and more debt.

is a second-order effect in practice. (The biggest effect would be if companies could issue riskless perpetual debt, an assumption Profs. Modigliani and Miller explored in 1963, in the second seminal paper;[3] this assumption could *not* be true for a real company.) Prof. Robert A. Taggart provides a unified treatment of the main papers in this literature and shows how various cases relate to one another.[4] Perhaps the most useful set of benchmark equations for the case where only corporate taxes matter are:

$$r_2^* = r_{A2} - r_D \times t_C \times \left(\frac{D}{V}\right) \tag{E-2a}$$

$$r_2^* = r_{E2} \times \left(\frac{E}{V}\right) + r_D \times \left(\frac{D}{V}\right) \times (1 - t_C) \tag{E-2b}$$

which imply for the cost of equity,

$$r_{E2} = r_{A2} + (r_{A2} - r_D) \times \left(\frac{D}{E}\right) \tag{E-2c}$$

where the variables have the same meaning as before but the "2" subscripts indicate the case that considers corporate but not personal taxes.

Note that Equation (E-2a) implies that when only corporate taxes matter, the overall after-tax cost of capital declines steadily as more debt is added, until it reaches a minimum at 100 percent debt (i.e., when D/V = 1.0). Note also that Equation (E-2c) still implies an exponentially increasing cost of equity as more and more debt is added. In fact, except for the subscript, Equation (E-2c) looks just like Equation (E-1c).

However, whether any value is added and whether the cost of capital changes at all also depends on the effect of taxes at the personal level.

[4] Robert A. Taggart, Jr. (1991), "Consistent Valuation and Cost of Capital Expressions with Corporate and Personal Taxes," *Financial Management* 20, pp. 8-20.

3. Personal Tax Burden on Interest Expense

Q7. How do personal taxes affect the results?

A7. Ultimately, the purpose of investment is to provide income for consumption, so personal taxes affect investment returns. For example, in the U.S., municipal bonds have lower interest rates than corporate bonds because their income is taxed less heavily at the personal level. In general, capital appreciation on common stocks is taxed less heavily than interest on corporate bonds because (1) taxes on unrealized capital gains are deferred until the gains are realized, and (2) the capital gains tax rate is lower. Dividends are taxed less heavily than interest, also, under current tax law.[5] The effects of personal taxes on the cost of common equity are hard to measure, however, because common equity is so risky.

Professor Miller, in his Presidential Address to the American Finance Association,[6] explored the issue of how personal taxes affect the overall cost of capital. The paper pointed out that personal tax effects could offset the effect of corporate taxes entirely.

Q8. Is it likely that the effect of personal taxes will completely neutralize the effect of corporate taxes?

A8. I do not believe so, although the likelihood of such a result would be increased if the current federal tax reductions on dividends and capital gains became permanent rather than expiring in 2010. However, personal taxes are important even if they do not make the corporate tax advantage on interest vanish entirely. Capital gains and dividend tax advantages definitely convey some personal tax advantage to equity, and even a partial personal advantage to equity reduces the corporate advantage to debt.

---

[5] The current maximum personal tax rate on dividend income was extended to the end of 2010 by the President on May 17, 2006. It is uncertain whether the reduced rates on dividend income will be further extended.

[6] Merton H. Miller (1977), "Debt and Taxes," *The Journal of Finance*, 32: 261-276, the third of the seminal papers mentioned earlier.

The Taggart paper explores the case of a partial offset, also. With personal taxes, the risk-free rate on the security market line is the after-personal-tax rate, which must be equal for risk-free debt and risk-free equity.[7] Therefore, the pre-personal-tax risk-free rate for equity will generally not be equal to the pre-personal-tax risk-free rate for debt. In particular, $r_{fE} = r_{fD} \times [(1-t_D)/(1-t_E)]$, where r_{fE} and r_{fD} are the risk-free costs of equity and debt and t_E and t_D are the personal tax rates for equity and debt, respectively. In terms of the cost of debt, the Taggart paper's results imply that a formal statement of these effects can be written as:[8]

$$r_3^* = r_{A3} - r_D \times t_N \times \left(\frac{D}{V}\right) \quad \text{(E-3a)}$$

$$= r_{E3} \times \left(\frac{E}{V}\right) + r_D \times \left(\frac{D}{V}\right) \times (1 - t_C) \quad \text{(E-3b)}$$

which imply

$$r_{E3} = r_{A3} + \left[r_{A3} - r_D \times \left(\frac{1-t_D}{1-t_E}\right)\right] \times \left(\frac{D}{E}\right) \quad \text{(E-3c)}$$

Suppose, for example, that $t_C = 0.35$ percent, $t_E = 7.7$ percent and $t_D = 40$ percent. Then $[(1-t_D)/(1-t_E)] = 0.65 = (1-t_C)$. That condition corresponds to Miller's 1977 paper, in which the net personal tax advantage of equity fully offsets the net corporate tax advantage of debt. Note also that in that case, $t_N = 0$.[9] Therefore, if the personal tax advantage on equity fully offsets the corporate tax advantage on debt, Equation (E-3a) confirms that the overall after-tax cost of capital is a constant.

---

[7] As Prof. Taggart notes (his footnote 9), it is not necessary that a specific, risk-free equity security exist as long as one can be created synthetically, through a combination of long and short sales of traded assets. Such constructs are a common analytical tool in financial economics.

[8] The net all-tax effect of debt on the overall cost of capital, t_N, equals $\{[t_C + t_E - t_D - (t_C \times t_E)] / (1 - t_E)\}$, where t_D is the personal tax rate on debt, as before. This measure of net tax effect is designed for use with the cost of debt in Equation (E-3a), which seems more useful in the present context. The Taggart paper works with a similar measure, but one which is designed for use with the cost of risk-free equity in the equivalent Taggart equation.

[9] In the above example, $t_N = \{[0.35 + 0.077 - 0.4 - (0.35 \times 0.077)] / (1.0 - 0.077)\} = 0.0/0.923 = 0$.

However, it is unlikely that the personal tax advantage of equity fully offsets the corporate tax advantage of debt. If taxes were all that mattered (i.e., if there were no other costs to debt), the overall after-corporate-tax cost of capital would still fall as debt was added, just not as fast.

Finally, note that the overall after-tax cost of capital, Equation (E-3b), still uses the corporate tax rate even when personal taxes matter. Equations (E-2b) and (E-3b) both correspond to the usual formula for the ATWACC. Personal taxes affect the way the cost of equity changes with capital structure -- Equation (E-3c) -- but not the formula for the overall after-tax cost of capital given that cost of equity.

B. NON-TAX EFFECTS

Q9. Please describe the non-tax effects of Debt.

A9. If debt is truly valuable, firms should use as much as possible, and competition should drive firms in a particular industry to the same, optimal capital structure for the industry. If debt is harmful on balance, firms should avoid it. Neither picture corresponds to what we actually see. A large economic literature has evolved to try to explain why.

Part of the answer clearly is the costs of excessive debt. Here the results cannot be reduced to equations, but they are no less real for that fact. As companies add too much debt, the costs come to outweigh the benefits. Too much debt reduces or eliminates financial flexibility, which cuts the firm's ability to take advantage of unexpected opportunities or weather unexpected difficulty. Use of debt rather than internal financing may be taken as a negative signal by the market.

Even if the company is generally healthy, more debt increases the risk that the company cannot use all of the interest tax shields in a bad year. As debt continues to grow, this problem grows and others may crop up. Management begins to worry about meeting debt payments instead of making good operating decisions. Suppliers are less willing to extend trade credit, and a liquidity shortage can translate into lower operating profits.

Ultimately, the firm might have to go through the costs of bankruptcy and reorganization. Collectively, such factors are known as the costs of "financial distress."[10]

The net tax advantage to debt, if positive, is affected by costs such as a growing risk that the firm might have to bear the costs of financial distress. First, the expected present value of these costs offsets the value added by the interest tax shield. Second, since the likelihood of financial distress is greater in bad times when other investments also do poorly, the possibility of financial distress will increase the risks investors bear. These effects increase the variability of the value of the firm. Thus, firms that use too much debt can end up with a higher overall cost of capital than those that use none.

Other parts of the answer include the signals companies send to investors by the decision to issue new securities, and by the type of securities they issue. Other threads of the literature explore cases where management acts against shareholder interests, or where management attempts to "time" the market by issuing specific securities under different conditions. For present purposes, the important point is that no theory, whether based on taxes or on some completely different issue, has emerged as "the" explanation for capital structure decisions by firms. Nonetheless, despite the lack of a single "best" theory, there is a great deal of relevant empirical research.

Q10. What does that research show?

A10. The research does not support the view that debt makes a material difference in the value of the firm, at least not once a modest amount of debt is in place. If debt were truly valuable, competitive firms should use as much debt as possible short of producing financial distress, and competitive firms that use less debt ought to be less profitable. The research shows exactly the opposite.

[10] See, for example, Section 18.3 of Brealey, Myers and Allen, 2006, *Principles of Corporate Finance*, 8th Edition, McGraw-Hill/Irwin, 2006.

For example, Kester[11] found that firms in the same industry in both the U.S. and Japan do not band around a single, "optimal" capital structure, and the most profitable firms are the ones that use the *least* debt. This finding comes despite the fact that both countries at the time (unlike the U.S. currently) had fully "classical" tax systems, in which dividends are taxed fully at both the corporate and personal level. Wald[12] confirms that high profitability implies low debt ratios in France, Germany, Japan, the U.K., and the U.S. Booth *et al.* find the same result for a sample of developing nations.[13] Fama and French[14] analyze over 2000 firms for 28 years (1965-1992, inclusive) and conclude, "Our tests thus produce no indication that debt has net tax benefits."[15] A paper by Graham[16] carefully analyzes the factors that might have led a firm not to take advantage of debt. It confirms that a large proportion of firms that ought to benefit substantially from use of additional debt, including large, profitable, liquid firms, appear not to use it "enough."

This research leaves us with only three options: either (1) apparently good, profit-generating managers are making major mistakes or deliberately acting against shareholder interests, (2) the benefits of the tax deduction on debt are less than they appear, or (3) the non-tax costs to use of debt offset the potential tax benefits. Only the first of these possibilities is consistent with the view that the tax deductibility of debt conveys a material cost advantage. Moreover, if the first explanation were interpreted to mean that otherwise good managers are acting against shareholder interests, either

deliberately or by mistake, it would require the additional assumption that their competitors (and potential acquirers) let them get away with it.

Q11. Are there any explanations in the financial literature for this puzzle other than stupid or self-serving managers at the most profitable firms?

A11. Yes. For example, Stewart C. Myers, a leading expert on capital structure, made it the topic of his Presidential Address to the American Finance Association.[17] The poor performance of tax-based explanations for capital structure led him to propose an entirely different mechanism, the "pecking order" hypothesis. This hypothesis holds that the net tax benefits of debt (i.e., corporate tax advantage over personal tax disadvantage) are at most of a second order of importance relative to other factors that drive actual debt decisions.[18] Similarly, Baker and Wurgler (2002)[19] observe a strong and persistent impact that fluctuations in market value have on capital structure. They argue that this impact is not consistent with other theories. The authors suggest a new capital structure theory based on market timing -- capital structure is the cumulative outcome of attempts to time the equity market.[20] In this theory, there is no optimal capital structure, so market timing financing decisions just accumulate over time into the capital structure outcome. (Of course, this theory only makes sense if investors do not recognize what managers are doing.)

[18] See also Stewart C. Myers (1989), "Still Searching for Optimal Capital Structure," *Are the Distinctions Between Debt and Equity Disappearing?,* R.W. Kopke and E. S. Rosengren, eds., Federal Reserve Bank of Boston.

[19] Malcolm Baker and Jeffrey Wurgler (2002), "Market Timing and Capital Structure," *The Journal of Finance* 57:1-32.

[20] *Ibid.*, p. 29.

Q12. Do inter-firm differences within an industry explain the wide variations in capital structure across the firms in an industry?

A12. No. This view is contradicted by the empirical research. As mentioned before, it has long been found that the most profitable firms in an industry, i.e., those in the best position to take advantage of debt, use the least.[21] Graham (2000) carefully examines differences in firm characteristics as possible explanations for why firms use "too little" debt and concludes that such differences are *not* the explanation: firms that ought to benefit substantially from more debt by all measurable criteria, if the net tax advantage of debt is truly valuable, voluntarily do not use it.[22]

Nor does the research support the view that firms are constantly trying to adjust their capital structures to optimal levels. Additional research on the pecking order hypothesis demonstrates that firms do not tend towards a target capital structure, or at least do not do so with any regularity, and that past studies that seemed to show the contrary actually lacked the power to distinguish whether the hypothesis was true or not.[23] In the words of the Shyam-Sunder - Myers paper p. 242, "If our sample companies did have well-defined optimal debt ratios, it seems that their managers were not much interested in getting there."

---

[21] For example, Kester, *op. cit.* and Wald, *op. cit.*

[22] While not contradicting Graham's finding that differences in firm characteristics do not explain capital structure differences, Nengjiu Ju, Robert Parrino, Allen M. Poteshman, and Michael S. Weisbach, "Horses and Rabbits? Trade-Off Theory and Optimal Capital Structure," *Journal of Financial and Quantitative Analysis*, June 2005, pp. 1-24, looks at the issue in a different manner. Their paper uses a dynamic rather than static model to analyze the tradeoff between the tax benefits of debt and the risk of financial distress. It finds that bankruptcy costs by themselves are enough to explain observed capital structures, once dynamic effects are considered. This means debt is not as valuable as suggested by the traditional static analysis (of the sort used by Graham).

[23] Lakshmi Shyam-Sunder and Stewart C. Myers (1999), "Testing static tradeoff against pecking order models of capital structure," *Journal of Financial Economics* 51:219-244.

II. EXPANDED EXAMPLE

Q13. What topics do you cover in this section?

A13. The discussion in my testimony did not detail the impact of different starting points for the level of debt nor did it address income earned on the investment, interest expense, or taxes. This section covers these topics. First, it discusses how the level of debt affects the cost of equity. Second, it addresses the influence of income and interest on the investment. Third, it explains the impact of taxes on capital structure decisions. The final topic covered in this section is the combined consequence of tax and non-tax effects of debt.

A. DETAILS OF DIFFERENT LEVELS OF DEBT

Q14. Why does more debt mean more risk for equity holders?

A14. Debt magnifies the variability of the equity return. As a simple example, think of an investor who takes money out of her savings and invests $100,000 in real estate. The future value of the real estate is uncertain. If the real estate market booms, she wins. If the real estate market goes down, she loses. Figure E-1 below illustrates this.

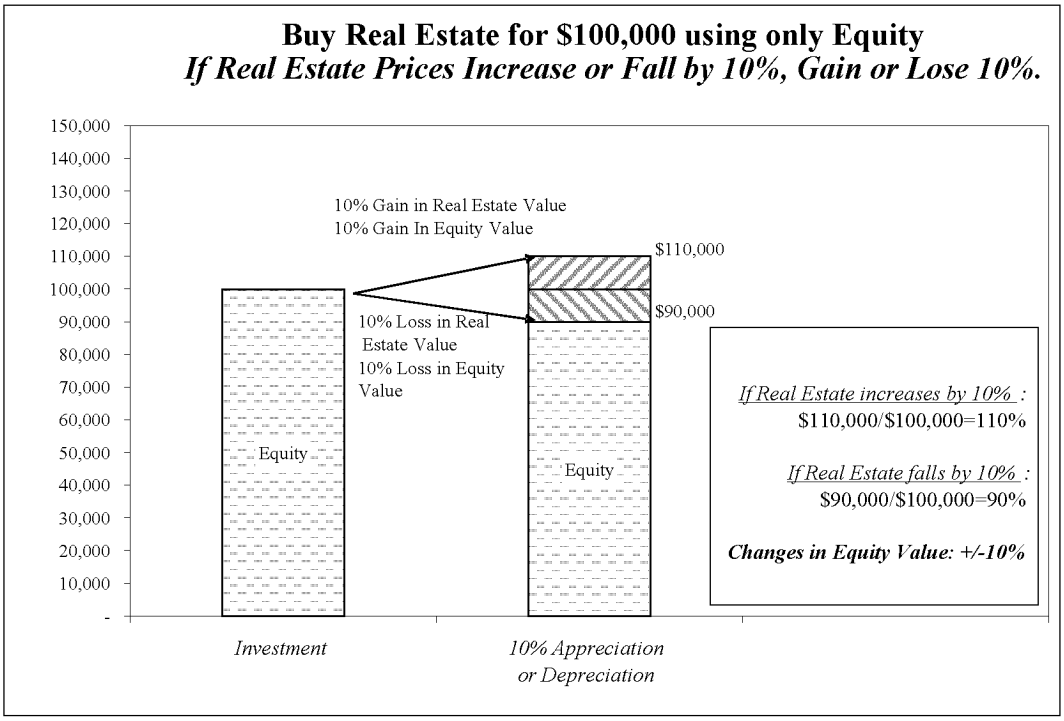

Figure E-1

In the scenario above, the investor financed her real estate purchase through 100 percent equity. Suppose instead that the investor had financed 50 percent of her real estate investment with a mortgage of $50,000. The mortgage lender does not expect to share in any benefits from increases in real estate values. Neither does the mortgage lender expect to share in any losses from falling real estate values, i.e., the investor carries the entire risk of fluctuating real estate prices. Figure E-2 illustrates this effect.

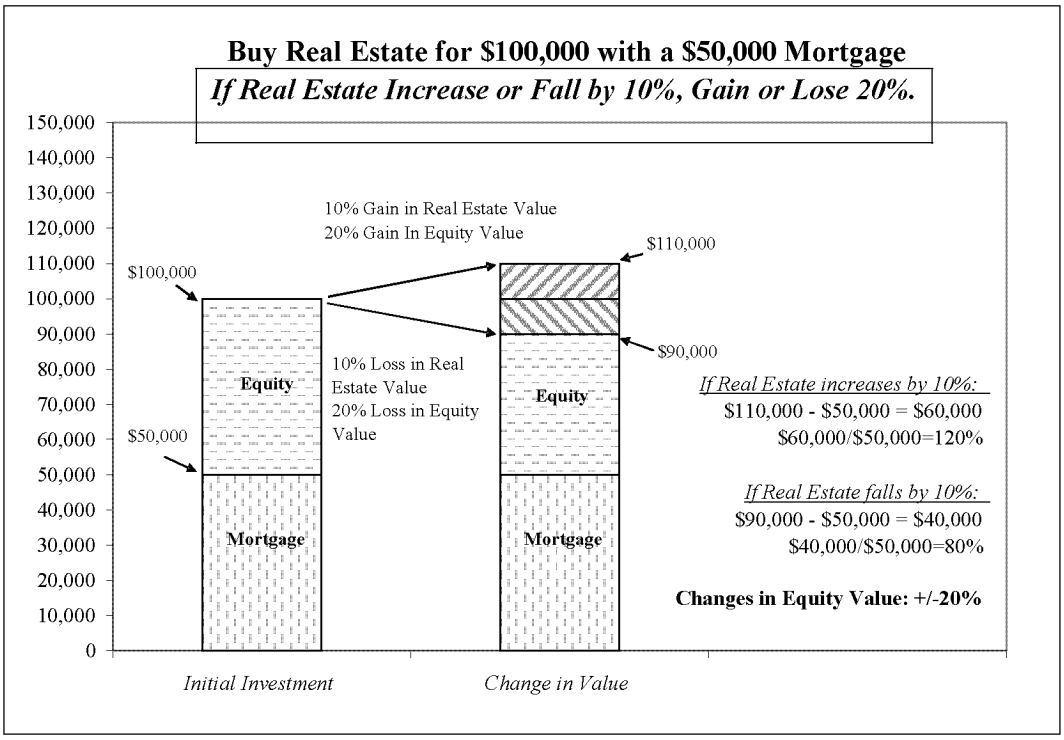

Figure E-2

In Figure E-2 where the investor financed her purchase through 50 percent equity and 50 percent debt, the variability in the investor's equity return is two times greater than that of Figure E-1. The entire fluctuation of 10 percent from rising or falling real estate prices falls on the investor's $50,000 equity investment. The lesson from the example is obvious, debt adds risk to equity.

Q15. What happens if the investor finances the real estate purchase with different proportions of debt?

A15. The equity return becomes more variable when the mortgage percentage is a greater proportion of the initial price. Table E-1 below calculates the return on equity when real estate prices increase by 10 percent when mortgages are 0 percent, 30 percent, 50 percent, and 70 percent of the initial price.

Table E-1: The Impact of Leverage on the Return on Equity

	100% Equity	70% Equity	50% Equity	30% Equity
Debt	$0	$30,000	$50,000	$70,000
Original Equity Investment	$100,000	$70,000	$50,000	$30,000
Increase in Market Value of Equity	$10,000	$10,000	$10,000	$10,000
Return on Equity Investment	10%	14.3%	20%	33.3%

Note that going from 70 percent equity down to 50 percent equity increases the return on the equity investment by 5.7 percent while going from 50 percent equity to 30 percent equity increases the return on equity by 13.3 percent. This illustrates a general point; the rate of return on equity increases more quickly at higher levels of debt than at lower levels. Investors demand a higher equity rate of return to bear more risk and debt magnifies equity's risk at an ever increasing rate. Therefore, the required equity rate of return goes up at an ever increasing rate as debt is added. This is not only basic finance theory, it is the everyday experience of anyone who buys a home. The bigger the mortgage, the more percentage risk the equity faces from changes in housing prices.

Q16. Please provide an example that illustrates why market values are relevant.

A16. Suppose in the above example that the investor has invested in real estate 10 years ago. Further assume that depreciation has reduced the book value of the real estate from $100,000 to $75,000 and assume the investor has paid off 40 percent of his $50,000 mortgage. Thus, the investor has a remaining mortgage of $30,000 (= 60% × $50,000). The book value of the investor's equity investment is therefore $45,000 (= $75,000 - $30,000).

What happens now if real estate prices rise or fall 20 percent? To answer that question, we need to know how real estate prices have developed over the past 10 years. If the

market value of the real estate now is $200,000 then a 20 percent decrease in the price of real estate ($40,000) is almost equal to the investor's book value equity. However, his market value equity (or net worth) is equal to the value of the real estate minus what he owes on the mortgage. If we assume that the market value of the mortgage equals the unpaid balance ($30,000), then the investor's net worth is calculated as follows:

Net Worth	=	Market Value of Real Estate	-	Remaining Mortgage
	=	$200,000	-	$30,000
	=	$170,000		

Therefore, the rate of return on equity due to a 20 percent decline in real estate prices is calculated in Table E-2.

Table E-2: Calculating the Rate of Return on Equity

Decline in Real Estate Value	$40,000
Market-Value Equity	$170,000
Rate of Return on Equity	- $40,000/$170,000 = -23.5%

B. THE IMPACT OF INCOME AND INTEREST

Q17. How does earning income from the investment and paying interest on debt affect the results?

A17. In the following explanation, I ignore income taxes which I deal with in Section C below. Assume the investor is receiving income, e.g., rent, from the real estate. Specifically, assume the investor receives $500 per month in income after all non-interest expenses ($6,000 per year). Also, assume that the expected appreciation is 5 percent per year, so

the expected market value is $105,000 after one year. Then the expected rate of return from the real estate with all equity financing is:

$$\text{Expected Return on Equity @ 0\% debt} = \frac{\text{Expected Net Income + Expected Appreciation}}{\text{Initial Investment}}$$

$$= \frac{\$6{,}000 + (\$105{,}000 - \$100{,}000)}{\$100{,}000}$$

$$= 11\%$$

Now suppose that the mortgage interest rate were 5 percent. Then at a mortgage equal to 50 percent, or $50,000, interest expense would be ($50,000 x 0.05), or $2,500. The expected equity rate of return would be:

$$\text{Expected Return on Equity @ 50\% debt} = \frac{\text{Expected (Net Income + Appreciation) – Int. Expense}}{\text{Initial } \textit{Equity} \text{ Investment}}$$

$$= \frac{\$6{,}000 + \$5{,}000 - \$2{,}500}{\$50{,}000}$$

$$= 17\%$$

Notice that the expected return on equity is higher as is the risk carried by equity.

Q18. Can you provide a more general illustration?

A18. Yes. Figure E-3 uses these assumptions at different mortgage levels to plot both (i) the expected rate of return on the equity in the dwelling, and (ii) the realized rate of return on

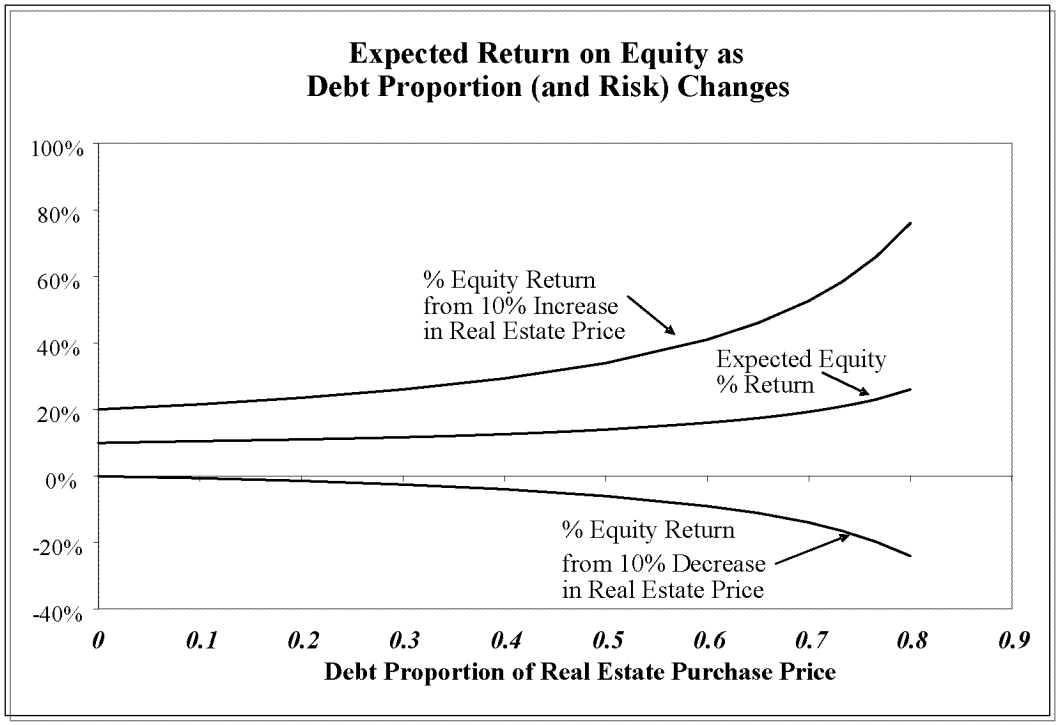

Figure E-3

that equity in a year if the dwelling value increases by 10 percent more than the expected 5 percent rate (i.e., if the value increases by 15 percent) or by 10 percent less than expected (i.e., if it decreases by 5 percent).[24]

The expected rate of return on equity increases at an increasing rate as the investor finances more and more of the real estate through loans (e.g., with a mortgage). Since equity bears all the risk of increases or decreases in real estate values (absent financial distress or bankruptcy), the amount of risk the buyer bears grows at an ever increasing rate as the mortgage percentage also increases.

Q19. What are the implications of this example?

A19. Any time an individual or a company uses debt to finance part an investment, the same risk magnifies. For example, if an investor buys stocks "on margin" -- by borrowing part

[24] For simplicity, the figure assumes the debt's interest rate is independent of the debt proportion. This might not always be true, and in general would not be true for a corporation that issued debt. However, the general shape of the graphs remains the same.

of the money used to buy the stock -- the expected rate of return will be higher as will the risks the investor carries. As an everyday example, imagine investing your retirement savings in a stock portfolio bought with as much margin as possible. If you were lucky, you could end up living very well in retirement. But you would be taking a lot of risk on the opposite outcome, since your portfolio could decline by more than 100 percent of your initial investment.

The same risk-magnifying effects happen when companies borrow to finance part of their investments.

C. THE EFFECT OF TAXES

Q20. What is the impact of taxes?

A20. Analyzing the net effect of taxes in capital structure decisions by corporations is an important part of the financial research. (Other parts of that research address such issues as the risk of financial distress or bankruptcy, and the signals corporations send investors by the choice of how to finance new investments.) The bottom line is that taxes complicate the picture without changing the basic conclusion.

Q21. Please describe the potential impact of taxes.

A21. Interest expense is tax-deductible for corporations. That increases the pool of cash the corporation gets to keep out of its operating earnings (i.e., its earnings before interest expense). With no debt, 100 percent of operating income is subject to taxes. With debt, only the equity part of the operating income is subject to taxes.

All else equal, the extra money kept from operating income increases the value of the corporation. The standard way to recognize that increase in value is to use an after-tax weighted-average cost of capital as a discount rate when valuing a company's operating cash flows.

Q22. Do personal taxes affect the value of debt, too?

A22. Yes, but in the other direction. One offset to debt's tax benefits at the corporate level is its higher tax burden at the personal level. Investors care about the money they get to keep after all taxes are paid, and while the corporation saves taxes by opting for debt over equity, individuals pay more taxes on interest than on capital gains from equity (and for now, on dividends as well).

Q23. Are there factors other than taxes matter?

A23. Absolutely, "all else" does not remain equal as more debt is added. The more debt, the more the non-tax effects of debt offset the tax benefits. Other costs include such effects as a loss of flexibility, the possibility of sending negative signals to investors, and a host of costs and risks associated with the danger of financial distress.

Q24. Does the tradeoff between the tax and non-tax effects of debt mean that firms have well-defined, optimal capital structures?

A24. No, this sort of "tradeoff" model does not explain actual corporate behavior. A substantial body of economic research confirms that real-world corporations act as if, after a moderate amount of debt is in place, the tax benefits of debt are not worth debt's other costs. In country after country and in industry after industry, the most profitable corporations in an industry tend to use the least debt. The research on this point is quite thorough, and the finding that the most profitable companies tend to use the least debt in a given industry is robust. Yet these are the companies with the most operating income to shield from taxes, who would benefit most if interest tax shields were truly valuable net of debt's other costs. They also presumptively are the best-managed on average (else why are they the most profitable?). This means it is unrealistic to suppose that more debt is always better, or that greater tax savings due to higher interest expense always add value to the firm on balance.

Q25. If the tradeoff model doesn't explain capital structure decisions by firms, is there a model that does?

A25. No single model has (yet) emerged as 'the" explanation of capital structure. However, several alternative models attempt to model the tradeoff (e.g., the "pecking order" hypothesis and "agency cost" explanations).

Q26. What does the absence of an agreed theory of capital structure in the financial literature imply about the overall effect of debt on the value of the firm?

A26. The findings of the financial literature mean that within an industry, there is no well-defined optimal capital structure. The use of some debt does convey some value advantage in most industries, but that advantage is offset by other costs as firms add more debt.[25] The range of capital structures over which the value of the firm in any industry is maximized is wide and should be treated as flat. The location and level of that range, however, does vary from industry to industry, just as the overall cost of capital varies from industry to industry.

Figure E-4 illustrates the picture that emerges from the research. This figure shows the present value of an investment in each of four different industries. For simplicity, the investment is expected to yield $1.00 per year forever. For firms in relatively high-risk industries (Industry 1 in the graph, the lowest line), the $1.00 perpetuity is not worth much and any use of debt decreases firm value. For firms in relatively low-risk industries (Industry 4 in the graph), the perpetuity is worth more and substantial amounts of debt make sense. Industries 2 and 3 are intermediate cases.

The maximum net rate at which taxes can increase value in this figure equals 20 percent of interest expense, representing a balance between the corporate tax advantage to debt

[25] Note that if debt did increase the value of the firm materially, competition would tend to take that value away, since issuing debt is an easy-to-copy competitive strategy. Prices would fall as firms copied the strategy, lowering operating earnings and passing the net tax advantages to debt through to customers (just as happens under rate regulation). Therefore, if also there were a narrow range of optimal capital structures within an industry, competition would drive all firms in the industry to capital structures within that range. This does not happen in practice, which contradicts one or both of the assumptions, i.e., (1) that debt adds material value on balance, and/or (2) that there is a narrow range of optimal capital structures.

and the personal tax disadvantage. The figure plots the maximum possible impact of taxes on value as a separate line, starting at the all-equity value of the lowest-risk industry (Industry 4).

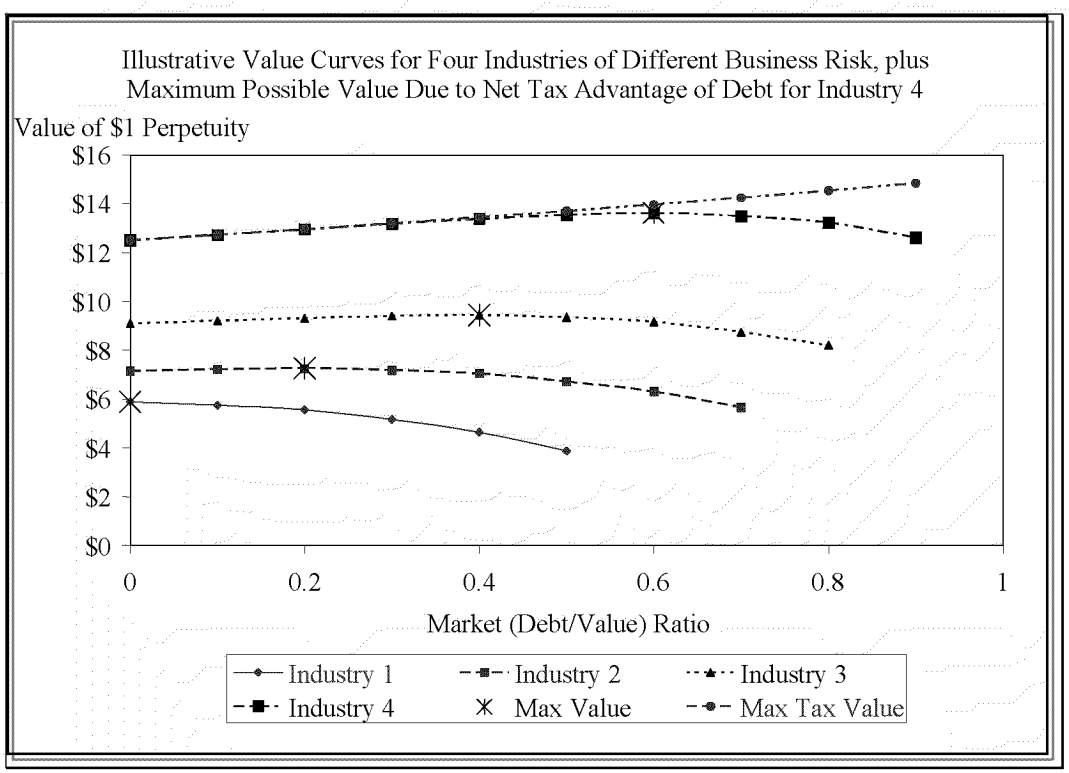

Figure E-4

Figure E-4 identifies a particular point as the maximum value on each of the four curves. However, the research shows that reliable identification of this maximum point, except in the extreme case where no debt should be used, is impossible. In accord with the research, the graph is prepared so that in none of the industries does a change in capital structure make much difference near the top of the curve. Even Industry 4, which increases in value at the maximum rate as quite a lot of debt is added, eventually must reach a broad range where changes in the debt ratio make little difference to firm value, given the research. For Industry 4, debt makes less than a 2 percent difference in the total value of the firm for debt-to-value ratios between 40 and 70 percent. (While these

particular values are illustrative, numbers of this order of magnitude are the only ones consistent with the research.)

Q27. What does this imply for the overall cost of capital?

A27. Figure E-5 plots the after-tax weighted-average costs of capital ("ATWACCs") that correspond to the value curves in Figure E-4. This picture just turns Figure E-4 upside down.[26] All the same conclusions remain, except that they are stated in terms of the overall cost of capital instead of the overall firm value. In particular, except for high-risk industries, the overall cost of capital is essentially flat across a broad middle range of capital structures for each industry, which is the only outcome consistent with the research. For Industry 4, for example, the ATWACC changes by less than 15 basis points for debt-to-value ratios between 40 and 70 percent.

[26] Note that the actual estimated ATWACC at higher debt ratios will tend to underestimate the ATWACC that corresponds to the value curves in Figure E-4, which are depicted in Figure E-5, and so will tend to overestimate the value of debt to the firm. The reason is that some of the non-tax effects of excessive debt, such as a loss of financial flexibility, may be hard to detect and not show up in cost of capital measurement.

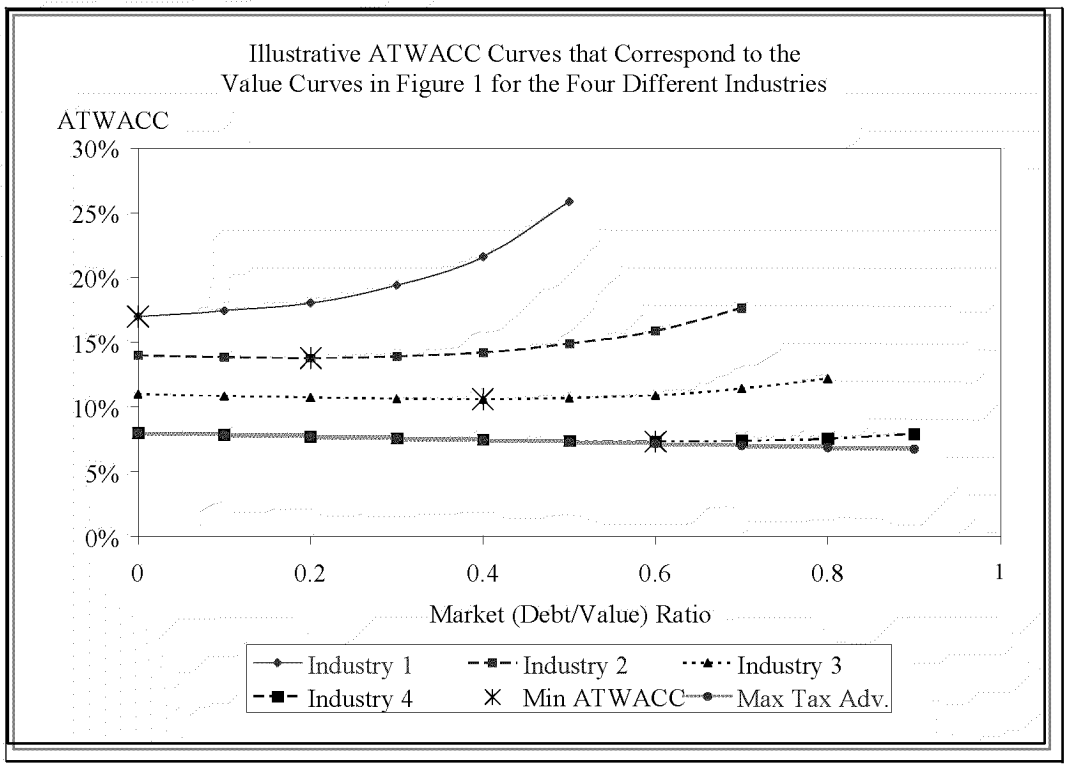

Figure E-5

Q28. How does this discussion relate to estimation of the right cost of equity for ratemaking purposes?

A28. When an analyst estimates the cost of equity for a sample of companies, s/he does so at the sample's actual market-value capital structure. That is, the sample evidence corresponds to ATWACCs that are already out somewhere in the broad middle range in which changes in the debt ratio have little or no impact on the overall value of the firm or the ATWACC.

An analyst therefore should assume the ATWACCs for the sample companies are literally flat. This assumption always provides the exact tradeoff between the cost of equity and capital structure at the literal minimum of the company's ATWACC curve. The research shows that this minimum is actually a broad, flat region, as depicted above. If the company happens to be somewhat to one side or the other of the literal minimum within this region, the recommended procedure may lead to a small understatement or overstatement of the amount that the cost of equity will change as capital structure

changes. The degree of this under- or overstatement, however, is very small compared to the inherent uncertainty in estimating the cost of equity in the first place. Otherwise, the financial research would have found very different results about the existence of a narrowly defined optimal capital structure.

D. COMBINED EFFECTS

Q29. Please summarize the implications for the combined impact of the tax and non-tax effects of debt.

A29. The most profitable firms do not behave as if the precise amount of debt they use makes any material difference to value, and competition does not force them into an alternative decision, as it would if debt were genuinely valuable. The explanation that fits the facts and the research is that within an industry, there is no well-defined optimal capital structure. Use of some debt does convey an advantage in most industries, but that advantage is offset by other costs as firms add more debt. The range of capital structures over which the value of the firm in any industry is maximized is wide and should be treated as flat. The location and level of that range, however, does vary from industry to industry, just as the overall cost of capital varies from industry to industry. To conclude that more debt does add more value, once the firm is somewhere in the normal range for the industry, is to conclude that corporate management in general is either blind to an easy source of value or otherwise incompetent (and that their competitors let them get away with it).

The finding that there is no narrowly defined optimal capital structure implies that analysts should estimate the ATWACCs for a sample of companies in a given industry and treat the average ATWACC value as independent of capital structure (at least within a broad middle range of capital structures). The right cost of equity for a rate-regulated company in the same industry is the number that yields the same ATWACC at the capital structure used to set the revenue requirement, since that is the cost of equity that

(estimation problems aside) the sample companies would have had if their market-value capital structures had been equal to the regulatory capital structure.

APPENDIX A: RESUMÉ

APPENDIX B: THE FERC METHODOLOGY: SAMPLE SELECTION AND THE DCF METHOD

TABLES AND WORKPAPERS

I. INTRODUCTION AND SUMMARY

Q1. Please state your name and address for the record.

A1. My name is Michael J. Vilbert. My business address is The Brattle Group, 44 Brattle Street, Cambridge, MA 02138, USA.

Q2. Please describe your job and your educational experience.

A2. I am a Principal of The Brattle Group, ("Brattle"), an economic, environmental and management consulting firm with offices in Cambridge, Washington, London, San Francisco and Brussels. My work concentrates on financial and regulatory economics. I hold a B.S. from the U.S. Air Force Academy and a Ph.D. in finance from the Wharton School of Business at the University of Pennsylvania.

Q3. What is the purpose of your testimony in this proceeding?

A3. I have been asked by Virginia Electric and Power Company, doing business as Dominion Virginia Power ("Dominion") to estimate the cost of equity that results from the implementation of the discounted cash flow ("DCF") method favored by the Federal Energy Regulatory Commission (the "FERC" or the "Commission") when applied to a sample of regulated electric utilities that are members of the PJM Interconnection, L.L.C. ("PJM"). This estimate is the return on equity that the Commission should allow Dominion an opportunity to earn on the equity-financed portion of its rate base for its electric transmission assets located in the PJM.

Q4. Please summarize how you approached this task.

A4. To accomplish this task, I estimate the cost of equity capital for a sample of regulated electric companies chosen according to the Commission's guidelines recently articulated in *Trans-Allegheny Interstate Line Co.*, 119 FERC ¶ 61,219 (2007) ("TrAILCo."); *Midwest Independent Transmission System Operator, Inc.*, 100 FERC ¶ 61,292 (2002) (*"MISO"*); and *Bangor Hydro-Electric Co.*, 117 FERC ¶ 61,129 (2006) ("New England Power"). This sample is called the Commission-Based Sample. A "range of

reasonableness" is then determined for the cost of equity by applying the Commission's preferred DCF methodology to these sample companies.[1]

Q5. Please summarize the parts of your background and experience that are particularly relevant to your testimony on these matters.

A5. Brattle's specialties include financial economics, regulatory economics, and the gas and electric industries. I have worked in the areas of cost of capital, investment risk and related matters for many industries, regulated and unregulated alike, in many forums. I have testified or filed cost of capital testimony before the Arizona Corporation Commission, the Pennsylvania Public Utility Commission, the Public Service Commission of West Virginia, the Public Service Commission of Ohio, the Tennessee Regulatory Authority, the Public Service Commission of Wisconsin, the South Dakota Utilities Commission, the California Public Utilities Commission, the Canadian National Energy Board, Alberta Energy and Utilities Board, the Ontario Energy Board, and the Labrador & Newfoundland Board of Commissioners of Public Utilities. I have also filed testimony before this Commission. Appendix A contains more information on my professional qualifications.

Q6. Are you sponsoring any exhibits?

A6. Yes. I am sponsoring Exhibit No. DVP-13. This exhibit contains the workpapers supporting Tables 1 and 2 of my testimony. The sources indicated in the footnotes to Tables 1 and 2 refer to material provided in Exhibit No. DVP-13.

Q7. What are the results from the application of the Commission's preferred DCF method to the Commission-Based Sample of regulated companies you have selected?

A7. The Commission's preferred DCF methodology results in a full "range of reasonableness" for the cost of equity between 7.85 and 17.56 percent, with a mid-point of 12.70 percent. Dominion's transmission business risk is comparable to that of the other regulated transmission owners in the PJM; therefore, the Commission's

[1] *See, e.g., S. Cal. Edison Co.*, 92 FERC ¶ 61,070, at 61,261-67 (2000) ("Opinion No. 445")(discussing the Commission's preferred estimation methodology).

methodology indicates an allowed return on equity of 12.70 percent, the midpoint of the range of reasonableness. After addition of the 50 basis points ("bps") adder for membership in a regional transmission organization ("RTO"), the appropriate allowed return would be 13.20 percent. Alternatively, if the highest individual sample company estimate were deleted, the Commission's preferred DCF model results in a range of 7.85 to 15.61 percent, with a mid-point of 11.73 percent. Therefore, an estimate of 11.73 percent for Dominion would be appropriate, which would be 12.23 percent with the RTO adder.

Q8. Are there other ways to estimate the cost of capital for a FERC regulated electric transmission company?

A8. Certainly, the determination of the cost of capital requires the application of informed judgment as well as science. There are many different approaches, and I have used other methods in other FERC proceedings.

Q9. Do you believe that your estimate from the FERC DCF method is the best estimate of Dominion's cost of equity for its transmission assets in the PJM in this proceeding?

A9. The cost of capital can be estimated in several ways, and I believe a risk positioning method is generally superior. Moreover, the FERC DCF method does not directly consider differences in financial risk among the sample companies or between the sample companies and the target company.[2] Had I considered these other approaches, I may very well have reached a different conclusion.

Q10. Why did you not implement these approaches in connection with this proceeding?

A10. The Commission has consistently rejected the use of alternative estimation methods in the past. While I believe that the Commission should not mechanically reject other methods of estimating the cost of capital, I also believe that whatever method the Commission ultimately chooses to use, it should be consistent in its approach from

[2] There are other differences in my standard approach that I believe result in procedures that are more consistent with the latest theoretical developments in finance.

proceeding to proceeding. The FERC prescribes the DCF method and has used it in many previous cases to establish the allowed return on equity for other transmission companies. It would be unfair and would increase regulatory uncertainty if the Commission were to apply its current DCF procedure in one proceeding and ignore it in another for similarly situated electric transmission companies. Selectively applying precedent potentially results in arbitrary estimates of the cost of capital and may result in an unjust and unreasonable allowed rate of return. In this case, Dominion has expressed an interest in minimizing controversy and receiving a return on equity based on faithfully applying the FERC's precedent. To this end, I have provided the best estimate possible. Specifically, the 11.73 percent baseline cost of equity is the result of applying the FERC's DCF methodology consistent with precedents in previous cases. It is also conservative in that it is the result of dropping the highest individual cost of equity estimate.

Q11. Considering all of the evidence what is the recommended return on equity for Dominion?

A11. I recommend that the Commission allow a proposed ROE of 12.23 percent which includes the 50 bps adder for RTO membership.

Q12. How is your testimony organized?

A12. *Section II* formally defines the cost of capital and touches on the principles relating to the estimation of the cost of capital for a business. *Section III* first describes the selection of the Commission-Based Sample. It then describes the Commission's current cost of capital estimation method based upon the DCF model and provides the results of the FERC DCF model for the Commission-Based Sample. The section concludes with the recommended cost of equity for Dominion's regulated transmission assets in the PJM.

II. COST OF CAPITAL THEORY

A. THE COST OF CAPITAL AND RISK

Q13. Please formally define the "Cost of Capital."

A13. The cost of capital can be defined as *the expected rate of return in capital markets on alternative investments of equivalent risk*. In other words, it is the rate of return investors require based on the risk-return alternatives available in competitive capital markets. The cost of capital is a type of opportunity cost: it represents the rate of return that investors could expect to earn elsewhere without bearing more risk. "Expected" is used in the statistical sense: the mean of the distribution of possible outcomes. The terms "expect" and "expected" in this testimony, as in the definition of the cost of capital itself, refer to the probability-weighted average over all possible outcomes.

The definition of the cost of capital recognizes a tradeoff between risk and return that is known as the "security market risk-return line," or "security market line" for short. This line is depicted in Figure 1. The higher the risk, the higher is the cost of capital. A version of Figure 1 applies for all investments. However, for different types of securities, the location (i.e., the intercept and the slope) of the line may depend on corporate and personal tax rates.

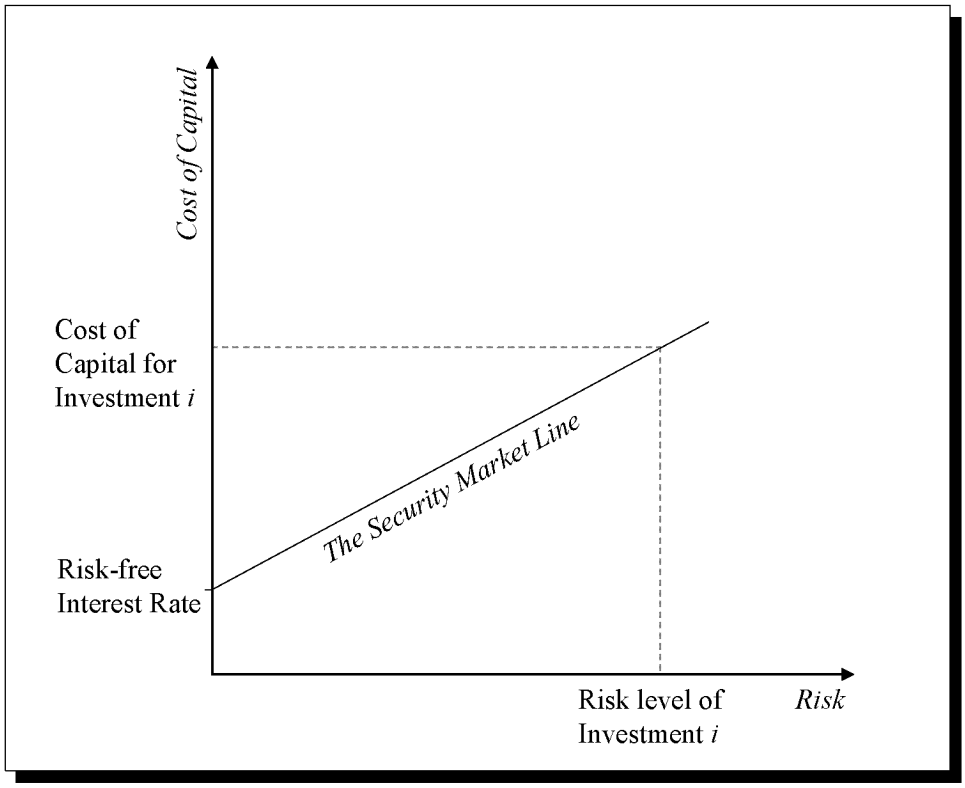

Figure 1: The Security Market Line

Q14. Why is the cost of capital relevant in rate regulation?

A14. It has become routine in U.S. rate regulation to accept the "cost of capital" as the right expected rate of return on utility investment.[3] That practice is normally viewed as consistent with the U.S. Supreme Court's opinions in *Bluefield Water Works & Improvement Co. v. Public Service Commission of West Virginia*, 262 U.S. 679 (1923), and *Federal Power Commission v. Hope Natural Gas Co.*, 320 U.S. 591 (1944).

From an economic perspective, rate levels that give investors a fair opportunity to earn the cost of capital are the lowest levels that compensate investors for the risks they bear. Over the long run, an expected return above the cost of capital makes customers overpay for service. Regulatory commissions normally try to prevent such outcomes unless there are offsetting benefits (*e.g.*, from incentive regulation that reduces future costs). At the

[3] A formal link between the cost of capital as defined by financial economics and the right expected rate of return for utilities is established by Stewart C. Myers, *Application of Finance Theory to Public Utility Rate Cases*, Bell J. of Econ. & Mgmt. Sci., 3:58-97 (1972).

same time, an expected return below the cost of capital does a disservice not just to investors but, importantly, to customers as well. In the long run, such a return denies the company the ability to attract capital, to maintain its financial integrity, and to expect a return commensurate with that of other enterprises attended by corresponding risks and uncertainties.

More important for customers, however, are the economic issues an inadequate return raises for them. In the short run, deviations of the expected rate of return on the rate base from the cost of capital may seemingly create a "zero-sum game"-- investors gain if customers are overcharged, and customers gain if investors are shortchanged. But in fact in the short run, such action may adversely affect the utility's ability to provide stable and favorable rates because some potential efficiency investments may be delayed or because the company is forced to file more frequent rate cases. In the long run, inadequate returns are likely to cost customers -- and society generally -- far more than is gained in the short run. Inadequate returns lead to inadequate investment, whether for maintenance or for new plant and equipment. The costs of an undercapitalized industry can be far greater than the short-run gains from shortfalls in the cost of capital. Moreover, in capital-intensive industries (such as the electric utility industry), systems that take a long time to decay cannot be fixed overnight. Thus, it is in the customers' interest not only to make sure the return investors expect does not exceed the cost of capital, but also to make sure that it does not fall short of the cost of capital, either.

Of course, the cost of capital cannot be estimated with perfect certainty, and other aspects of the way the revenue requirement is set may mean investors expect to earn more or less than the cost of capital even if the allowed rate of return equals the cost of capital exactly. However, a commission that sets rates so investors expect to earn the cost of capital on average treats both customers and investors fairly, and acts in the long-run interests of both groups.

B. INVESTMENT IN THE TRANSMISSION GRID

Q15. Has investment in the transmission grid generally been seen as adequate?

A15. No. The need for additional investment in the transmission grid appears to be widely acknowledged. For example, the following is a quotation from Chairman Kelliher:

> There has been a sustained period of underinvestment in the transmission system. Notwithstanding, use of the nation's grid has more than doubled in recent years. It is clear that we need to strengthen the system to meet consumer demand and today's rule takes a significant turn in that direction. Underinvestment in the grid is a national problem.[4]

Q16. Why do you raise this issue here?

A16. As noted above, it is in the interest of both customers and shareholders to provide an adequate rate of return if a regulated industry is to attract sufficient capital to maintain appropriate service levels in the long run. For the transmission grid, there continue to be concerns that investment has not been adequate.

Q17. Are you saying that the issues with the transmission grid have arisen because the allowed rate of return was inadequate over a sustained period of time?

A17. No, the cause of the under investment cannot be attributed to any single factor; however, the ongoing uncertainty associated with the restructuring of the industry may have led investors to question whether the allowed returns were adequate given that uncertainty.

Q18. Will an adequate allowed rate of return solve the problem of inadequate transmission investment?

A18. No, adequate rates of return alone are not enough to guarantee additional investment, but they are necessary. Investment in long-lived, inflexible assets is extraordinarily risky, and electric transmission assets are very long lived. In an environment in which full recovery of and on an investment in such long lived assets is not perceived to be assured, investment may lag particularly if the allowed return does not recognize the risk inherent

[4] Press Release, FERC, Final Rule Promoting Transmission Investment Adopted; Rate Incentives for Two Transmission Proposals Accepted (July 20, 2006) (available at http://www.ferc.gov/news/news-releases/2006/2006-3/07-20-06-E-3.asp#skipnavsub).

in such a circumstance. If the Commission wants investors to sink capital into transmission assets now, at an accelerated rate, it will be necessary to eliminate as many barriers as possible. A major potential barrier would be a fear on investors' part that investments will not earn returns adequate to justify the long-term risks involved.

Q19. How does this concern relate to Dominion at this time?

A19. Dominion plans to invest approximately $1.5 billion in transmission assets in the PJM through 2011.[5] An issue of concern is which customers will pay for the investment because the benefits of new transmission investment are frequently dispersed to customers not in the immediate location of the new transmission assets. As a result, disputes as to who benefits and who should pay arise that could make the timely recovery of new investment uncertain. In addition, in its final report for Docket No. 2007-OE-01, the Department of Energy ("DOE") designated the entire Mid-Atlantic area, including a substantial portion of the service territory of Dominion, as a National Interest Electric Transmission Corridor.[6] DOE's designation is based on studies demonstrating long-standing and increasing congestion on transmission lines in the region, including critical interfaces in Dominion's service area. As DOE points out in the press release, the states remain primarily responsible for addressing the critical congestion issues highlighted by these final corridor designations.

III. THE COMMISSION'S COST OF CAPITAL METHODOLOGY

Q20. How is this section of your testimony organized?

A20. This section first outlines the steps involved in selecting the Commission-Based Sample. It also describes the discounted cash flow method in general and then provides the

[5] For a description of the forecast transmission capital investment planned by Dominion, *see* John Smatlak Test., Exhibit No. DVP-1, at 3.

[6] *See* Press Release, U.S. Department of Energy, Office of Public Affairs, DOE Designates Southwest Area and Mid-Atlantic Area National Interest Electric Transmission Corridors, (October 2, 2007) (available at http.//www.doe.gov/news/5538.htm).

specifics of the implementation of the Commission's preferred DCF methodology. Finally, the results of calculations are presented.

A. THE COMMISSION-BASED SAMPLE

Q21. Please explain what criteria you applied in selecting a sample that is consistent with the Commission's precedent in regards to transmission.

A21. I have reviewed key Commission decisions and selected a sample of electric utilities based on criteria typically used by the Commission. I refer to this sample as the Commission-Based Sample.[7] Specifically, in order for a company (or its holding company) to be included in the Commission-Based Sample, I understand it has to meet all of the following conditions: have a direct link to the same RTO or ISO in which the applicant is located;[8] be publicly-traded and have available recent price and dividend data; pay dividends; have available growth rate data from *Value Line* or I/B/E/S (or comparable sources)[9]; and not be involved in recent, current or forecasted merger activity as of the date of the most recent growth rate data.

---

[7] My sample selection procedures for the Commission-Based Sample are derived from review of various materials including Opinion No. 445; *N.Y. State Elec. & Gas Corp.*, 92 FERC ¶ 61,169 (2000) ("Opinion No. 447"), *order on reh'g*, 100 FERC ¶ 61,021 (2002) ("Opinion No. 447-A"), *reh'g denied*, 101 FERC ¶ 61,037 (2002) ("Opinion No. 447-B"), *order on reh'g*, 103 FERC ¶ 61,321 (2003) ("Opinion No. 447-C"); *Devon Power LLC*, 103 FERC ¶ 61,155 (2003); *Midwest Indep. Transmission Sys. Operator, Inc.*, 100 FERC ¶ 61,292 (2002), *reh'g denied*, 102 FERC ¶ 61,143 (2003), *aff'd on remand*, 106 FERC ¶ 61,302 (2004); *Bangor Hydro-Elec. Co.*, 117 FERC ¶ 61,129 (2006) ("Opinion No. 489"), *reh'g granted for further consideration* (2006); and *Trans-Allegheny Interstate Line Co.*, 119 FERC ¶ 61,219 (2007), *reh'g denied*, 121 FERC ¶ 61,009 (2007).

[8] The meaning of a "direct link" is ambiguous. Other interpretations are possible, but in this proceeding I have interpreted it to mean that the sample companies should be transmission owners in the same RTO.

[9] I rely upon Bloomberg for analyst forecasts of earnings growth rates instead of I/B/E/S because I/B/E/S long-term growth rates are no longer accessible for non-members of Thomson Financial. I also use *Value Line* estimates.

1. The Commission-Based Sample Selection Criteria

Q22. Please describe your selection of the Commission-Based Sample.

A22. I started with the universe of electric companies that are members of the PJM Interconnection, of which Dominion is a member. I restricted the sample to include only companies that own transmission assets in the PJM area, as identified by the PJM on its website. I eliminated cooperatives, municipality-owned companies and state agencies. Of the remaining companies, I then determined each member company's parent holding company, and eliminated those that were not publicly traded or had no data available from Bloomberg. This initial screen resulted in thirteen companies remaining in the sample.[10] Of these, one was eliminated because it has not recently paid dividends, and two were eliminated because their primary business line is outside of the electric industry.[11] The remaining ten companies comprise the Commission-Based Sample: American Electric Power Company, Inc., Consolidated Edison, Inc., Constellation Energy Group, Inc., Dominion Resources, Inc. ("Dominion Resources"), DPL, Inc., Exelon Corp., FirstEnergy Corp., Pepco Holdings, Inc., PPL Corp., and Public Service Enterprise Group, Inc. Section I of Appendix B contains a detailed description of the sample selection procedure.

Q23. Why is it appropriate to include Dominion Resources, the parent of Dominion, in the sample?

A23. Dominion Resources meets all of the conditions necessary for inclusion in the sample. The company owns transmission assets in the PJM and fulfills all other data requirements necessary for inclusion in the sample. Including the parent holding company of a regulated subsidiary that is the subject of the regulatory proceeding would be of concern if there were issues of circularity. Circularity would potentially result if the outcome of the regulatory proceeding substantially affects the estimated cost of capital of the holding

[10] Only companies with traded stock were included in the sample. Therefore, multiple companies in PJM with the same parent only appear once in the sample.

[11] The decision to eliminate these two companies (UGI Holdings and Valero Power Marketing) from the sample is consistent with Commission precedent as affirmed in *New England Power*.

company which is part of the sample being used to estimate the appropriate cost of capital. In this case, Dominion's regulated transmission assets are such a small portion of the total assets of Dominion Resources that any such effect is likely to be so small as to be undetectable by any cost of capital method.

2. Characteristics of the Commission-Based Sample

Q24. Please describe the financial characteristics of the Commission-Based Sample.

A24. Table 1 below provides information on the sample including each sample company's 2006 revenue, bond rating, and its S&P business risk profile ranking.

Table 1: Characteristics of the Commission-Based Sample

Company	S&P Business Profile Risk [1]	Revenue (2006) ($MM) [2]	Regulated Electric Assets [3]	Market Cap. (2nd Qtr 2007) ($MM) [4]	S&P Bond Rating (2007) [5]	Sustainable Growth Rate [6]	BEst Long-Term Growth Estimate [7]
American Electric Power Co Inc	5	12,622	R	18,681	BBB	6.1%	5.7%
Constellation Energy Group Inc	7	19,285	D	15,913	BBB	12.5%	13.4%
Dominion Resources Inc	7	16,482	D	30,405	BBB	5.0%	5.4%
DPL Inc	6	1,394	R	3,289	BBB	9.8%	13.6%
Consolidated Edison Inc	2	12,137	R	12,900	A	3.1%	3.7%
Exelon Corp	7	15,655	MR	50,091	BBB	12.4%	8.8%
FirstEnergy Corp	7	11,501	MR	20,109	BBB	7.5%	8.1%
Public Service Enterprise Group Inc	7	12,164	MR	22,073	BBB	10.9%	11.0%
Pepco Holdings Inc	5	8,363	MR	5,475	BBB	4.2%	8.5%
PPL Corp	7	6,899	MR	17,870	BBB	7.9%	11.4%

B. THE DISCOUNTED CASH FLOW APPROACH

Q25. Please describe the discounted cash flow approach.

A25. The DCF model attempts to estimate the cost of capital in one step. The method assumes that the market price of a stock is equal to the present value of the dividends that its owners expect to receive. The method also assumes that this present value can be calculated by the standard formula for the present value of a cash flow stream:

$$P = \frac{D_1}{(1+k)} + \frac{D_2}{(1+k)^2} + \frac{D_3}{(1+k)^3} + \cdots + \frac{D_T}{(1+k)^T} \qquad \textbf{(1)}$$

where "P" is the market price of the stock; "D_t" is the dividend cash flow expected at the end of period t (i.e., subscript period 1, 2, 3 or T in the equation); "k" is the cost of capital; and "T" is the last period in which a dividend cash flow is to be received. The formula just says that the stock price is equal to the sum of the expected future dividends, each discounted for the time and risk between now and the time the dividend is expected to be received.

Very often, when the DCF is applied in regulatory proceedings, very strong (i.e., unrealistic) assumptions are used that yield a simplification of the standard formula, which then can be rearranged to estimate the cost of capital. Specifically, it is assumed that investors expect a dividend stream that will grow *forever* at a steady rate, and if so, the market price of the stock will be given by a very simple formula,

$$P = \frac{D_1}{(k-g)} \qquad \textbf{(2)}$$

where "D_1" is the dividend expected at the end of the first period, "g" is the perpetual growth rate, and "P" and "k" are the market price and the cost of capital, as before. Equation **(2)** is a simplified version of Equation **(1)** that can be solved to yield the well known "DCF formula" for the cost of capital:

$$k = \frac{D_1}{P} + g$$
$$= \frac{D_0 \times (1+g)}{P} + g \qquad \textbf{(3)}$$

where "D_0" is the current dividend, which investors expect to increase at rate g by the end of the next period, and the other symbols are defined as before. Equation **(3)** says that if Equation **(2)** holds the cost of capital equals the expected dividend yield plus the (perpetual) expected future (forever constant) growth rate of dividends. I refer to this as the simple DCF model because this simplification of the model relies on the use of very strong assumptions that are unlikely to reflect actual circumstances.

Q26. Are there other versions of the DCF models besides the "simple" one?

A26. Yes. The constant growth rate DCF model requires that dividends and earnings grow at the same rate for companies that earn their cost of capital on average.[12] It is inconsistent with the theory on which the model is based to have different growth rates in earnings and dividends over the period when growth is assumed to be constant. If the growth in dividends and earnings were expected to vary over some number of years before settling down into a constant growth period, then it would be appropriate to estimate a multistage DCF model. In the multistage model, earnings and dividends can grow at different rates, but must grow at the same rate in the final, constant growth rate period. A difference between forecasted dividend and earnings rates therefore is a signal that the facts do not fit the assumptions of the simple DCF model. Section II of Appendix B provides the details of my implementation of the FERC DCF method.

[12] Why must the two growth rates be equal in a steady-growth DCF model? Think of earnings as divided between reinvestment, which funds future growth, and dividends. If dividends grow faster than earnings, there is less investment and slower growth each year. Sooner or later dividends will equal earnings. At that point, growth is zero because nothing is being reinvested (dividends are constant). If dividends grow slower than earnings, each year a bigger fraction of earnings are reinvested. That makes for ever faster growth. Both scenarios contradict the steady-growth assumption. So if you observe a company with different expectations for dividend and earnings growth, you know the company's stock price and its dividend growth forecast are inconsistent with the assumptions of the steady-growth DCF model.

1. Strengths and Weaknesses of the DCF Approach

Q27. What are the merits of the DCF approach?

A27. The DCF approach is conceptually sound if its assumptions are met, but can run into difficulty in practice because those assumptions are so strong[13], and hence so unlikely to correspond to reality. Dividends, earnings and prices are unlikely to grow at a constant rate literally forever. Two conditions are also well known to be necessary for the DCF approach to yield a reliable estimate of the cost of capital: the variant of the present value formula that is used must actually match the variations in investor expectations for the growth of dividends, and the growth rate(s) used in that formula must match current investor expectations. Less frequently noted conditions may also create problems.

Q28. Is estimating the "right" dividend growth rate the most difficult part for the implementation of the DCF approach?

A28. Yes. Finding the right growth rate(s) is usually the "hard part" of a DCF application. The original approach to estimation of *g* relied on average historical growth rates in observable variables, such as dividends or earnings, or on the "sustainable growth" approach, which estimates *g* as the average book rate of return times the fraction of earnings retained within the firm. A major problem with using historical averages over periods with widely varying rates of inflation and costs of capital is that they are unlikely to equal current growth rate expectations.

Q29. Specifying the current price is straightforward, but how does one specify the expected stream of dividends for use in the model?

A29. This is the most difficult and subjective part of implementing the DCF methodology. Several models exist to simplify the process, and these generally transform the problem of specifying a stream of dividends into one of specifying a set of expected dividend growth rates. These DCF models are then distinguished by how they model expected growth rates. The Commission's preferred DCF model is a modification of the simple

[13] In this context "strong" means that the assumption is unlikely to match reality and that it also has a substantial impact on the model's results.

DCF model that relies upon two different estimates of the long-term growth. It is described next.

2. The Commission's Preferred DCF Model

Q30. Please describe the Commission's preferred DCF model.

A30. The Commission's preferred DCF model is a modification of the standard DCF model that uses a constant growth of dividends. The model is articulated in Opinion No. 445, at 61,262-63:[14]

> In the past, we have consistently applied a one-step, constant growth DCF model for calculating ROEs for electric utilities. The DCF methodology determines the ROE by summing the dividend yield (with an adjustment for the quarterly payment of dividends) and expected growth rate. The resulting formula is D/P (1+.5g) + g = k, where "D/P" is the dividend yield, "g" is the sustainable growth rate of dividends per share, and "k" is the resulting ROE. The sustainable growth rate is calculated by the following formula: g = br + sv, where "b" is the expected retention ratio, "r" is the expected earned rate of return on common equity, "s" is the percent of common equity expected to be issued annually as new common stock, and "v" is the equity accretion rate.

I disagree with the use of the 0.5 multiplier for the initial growth rate as a matter of economic principle, because it violates the basic assumptions of the DCF model. Nonetheless, I present results of the Commission's DCF method as described in Opinion No. 445 because the Commission has specified this version of the single-stage DCF model as its preferred estimation method for electric utilities.

Q31. Why do you disagree with the use of a 0.5 multiplier?

A31. The DCF model is derived under the assumption that dividends grow at the full growth rate for the period. However, as stated in Opinion No. 445, the Commission's approach results in a variation of this fundamental result displayed in Equation **(4)**:

[14] The Commission also calculates growth rates using analysts' earnings growth forecasts from I/B/E/S, using the same procedure to adjust the dividend yield. I use analogous growth rate forecasts from Bloomberg termed their BEst forecasts.

$$k = \frac{D_0 \times (1 + 0.5g)}{P} + g \qquad \textbf{(4)}$$

However, because it is the Commission's preferred method, I follow the Commission's precedent and use this version of the dividend yield in the DCF model.

Q32. Opinion No. 445 also references sustainable growth. Please explain how the sustainable growth rate is determined.

A32. Although companies can experience very high rates of growth from time to time (i.e., greater than growth of economy as a whole), these high rates cannot generally be expected to last indefinitely. Conversely, very low rates of growth can generally be expected to improve over time. As implied by the name, the sustainable growth rate of a company is that which can be expected to be maintained by the company through reinvestment of its earnings or additional equity issuances at prices above book value. The growth achieved by reinvestment of new earnings depends on both the amount of earnings retained, b = (1-Dividends/Net Income), and on the expected return on equity (r) those earnings will achieve. On the other hand, growth from new share issues depends on the percentage of new shares being issued, s, and the equity accretion ratio $v = \left[1 - \frac{1}{\textit{Market - to - Book Ratio}}\right]$. Together, the implied sustainable growth rate is given as shown in Equation **(5)**:

$$g = br + sv \qquad \textbf{(5)}$$

Q33. Is the sustainable growth rate the only growth rate you use in your implementation of the Commission's preferred DCF model?

A33. No. Consistent with the Commission's practice, I also implement a version of the model where g is set equal to the long-term earnings growth rates provided by securities analysts. My source is Bloomberg through their BEst Estimates.

Q34. How is the dividend yield determined?

A34. The high and low dividend yield is calculated as the 6-month average of the highest monthly closing prices or lowest monthly closing prices divided into the annualized current quarterly dividend, *i.e.*, the current dividend times 4. The result of combining the high and low dividend yields with the two estimates of the dividend growth rate is four estimates of the cost of equity for each sample company. The highest (lowest) of the four estimates is reported as the high (low) estimate for the company which in turn are used to establish the range of reasonableness for the sample. Details on the calculation of each parameter in Equations **(4)** and **(5)** above are provided in Appendix B.

C. THE COMMISSION-BASED RANGE OF REASONABLENESS

Q35. What are the results of the application of the Commission's DCF methodology to the sample of transmission-owning companies in the PJM?

A35. Table 2 below summarizes the results of the Commission's DCF methodology applied using data through September 2007, which is the most recent data available at this time. The table presents the high and low estimate for each company in the Commission-Based Sample as well as summary statistics for the sample.

Q36. What is the range of reasonableness from the sample?

A36. The estimates range from a high of 17.56 percent for DPL Inc. to a low of 7.85 percent for Pepco Holdings Inc. with a midpoint of 12.70 percent. Alternatively, if the highest cost of equity estimate is deleted as has sometimes been done in the past,[15] the top of the range is 15.61 percent for Constellation Energy Group Inc. In that case the range of reasonableness is 15.61 to 7.85 percent with a midpoint of 11.73 percent. Table 2 also

[15] For example, in *ISO New England Inc.*, 109 FERC ¶ 61,147 (2004) *("New England RTO Rehearing Order")*, the Commission affirmed the exclusion of an ROE estimate of 17.7 percent, asserting that it is "an extreme outlier" and would "skew the results" of the calculation (P 205). In the past, the Commission has not specifically defined what constitutes an outlier, but in *Midwest Indep. Transmission Sys. Operator, Inc.*, 106 FERC ¶ 61,302 (2004), an ROE value of 15.96 percent was not considered an outlier, based on the reasoning that it was not too different from the next highest ROE estimate, 14.9 percent (P 12). Based on these precedents, and in order to be conservative, I have dropped the highest estimate of 17.56 percent.

presents some other summary statistics including the median and average of the sample results with and without DPL's estimate.

Table 2: Results of the Commission's DCF Method

Company	Region	Implied Cost of Equity High [1]	Low [2]
American Electric Power Co Inc	PJM	9.62%	9.00%
Constellation Energy Group Inc	PJM	15.61%	14.48%
Dominion Resources Inc	PJM	8.86%	8.28%
DPL Inc	PJM	17.56%	13.45%
Consolidated Edison Inc	PJM	8.78%	7.86%
Exelon Corp	PJM	15.04%	11.14%
FirstEnergy Corp	PJM	11.38%	10.50%
Public Service Enterprise Group Inc	PJM	13.98%	13.57%
Pepco Holdings Inc	PJM	12.48%	7.85%
PPL Corp	PJM	14.30%	10.51%
Full Range		17.56%	7.85%
Midpoint		12.70%	
Median Estimate		11.26%	
Average		11.71%	
Range Excluding Highest Cost of Equity (DPL)		15.61%	7.85%
Midpoint		11.73%	
Median Estimate		11.14%	
Average		11.40%	

Sources and Notes:
[1]: See Table No. MJV-4, Panel A1, column [7], Exhibit No. DVP-13 at 4.
[2]: See Table No. MJV-4, Panel A1, column [8], Exhibit No. DVP-13 at 4.

Q37. Has the Commission relied on the midpoint or the median as the appropriate estimate of the cost of equity for the sample?

A37. For a company of comparable risk to the sample, the Commission has consistently relied upon the midpoint of the sample as the appropriate measure of the cost of equity for the sample.[16] In addition, the deletion of DPL Inc. results in a distribution of cost of equity estimates that is relatively symmetrical (i.e., is not skewed) as indicated by the fact that

[16] See Appendix B for a discussion of the decisions utilizing the midpoint in determining the allowed return.

the midpoint is only 33 bps higher than the average of the sample, and the median is only 26 bps lower than the sample average.

Q38. In Table 1 above, the estimated growth rates for the sample companies are displayed. Some of the annual growth rate estimates are greater than 12 percent. Are these growth rates sustainable?

A38. The question of sustainability depends critically on the length of time over which the growth rates would apply. Securities analysts generally limit their earnings growth rate forecasts to a five year period, and clearly they believe that the estimates they provide are sustainable over that period. The other set of growth rates used in the FERC DCF method are labeled "sustainable" growth rates because they are the product of the amount of earnings retained times the average return earning on equity. Growth rates estimated by application of the sustained growth rate methodology can be sustained as long as the company continues to retain earnings on which it earns the same average return on equity.

Q39. Are you saying that the growth rates could be sustainable forever?

A39. No. Growth rates for all companies vary over time, and no company can maintain a very high growth rate forever. Nor is it likely that very low current estimated growth rates would stay low forever. For purposes of the DCF analysis, the growth rates estimates are the best available estimates for the next five years.

Q40. What about the growth rates for year six and later?

A40. To my knowledge, there is no information available on the likely growth rate of earnings and dividends available for time periods more than five years in the future. Use of the DCF model is necessarily subject to this limitation. Analysts sometimes attempt to address this problem by making various assumptions about the likely growth path of dividends for the period beginning in year six. Given there is no recognized source of individual company data upon which to rely to make these assumptions, they are susceptible to the individual analyst's expectations as to the future.

Q41. What is your conclusion about the growth rates used in your application of the FERC DCF model?

A41. In my judgment, the question of whether the individual growth rates are sustainable is not a matter of concern in the current proceeding for two reasons. First, I believe that the five-year growth rates estimates used in the model come from widely recognized sources and are the best estimates currently available. Second, the FERC DCF methodology attempts to address the lack of data on long-term dividend growth rates by estimating the five-year growth rate in the two ways discussed above. The method then creates a range of reasonableness by looking to the highest and lowest estimates from the two growth rates and two dividend yield estimates. The likely motivation for this approach is the belief that the companies with high estimates are balanced by the companies with low estimates so that the estimation errors cancel out. If the sample is large enough, the expectation that the estimation errors for the growth rates are likely to cancel out is reasonable.

Q42. What are your conclusions from the FERC DCF model regarding the cost of equity for Dominion's regulated transmission assets in the PJM?

A42. As shown in Table 2 above, the midpoint of the range of reasonableness is 11.73 percent after deleting the highest cost of equity estimate from the sample. As noted above, the Commission has relied upon the midpoint as the best estimate of the cost of equity from the sample. In addition, Dominion's transmission assets are of comparable risk to that of other regulated transmission assets in the PJM so, following the FERC's approach in previous cases, the midpoint of the sample would be representative of the cost of equity for Dominion.

Q43. Given the results of the DCF model and Commission's precedent, what should be the allowed return on equity for Dominion's transmission assets in the PJM?

A43. Consistent with its precedent, the Commission should allow Dominion an 11.73 percent baseline return on equity to which should be added the 50 bps adder for membership in a

qualified RTO. The proposed total return on equity for use in the PJM's formula for determination of Dominion's transmission revenue requirement is 12.23 percent.

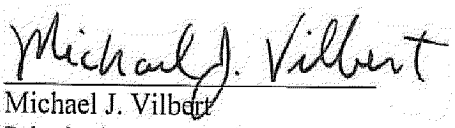
Q44. Does this conclude your testimony?

A44. Yes.

VERIFICATION

Pursuant to 28 U.S.C. § 1746 (2000), I state under penalty of perjury that the foregoing testimony is true and correct to the best of my information, knowledge and belief.

Executed this 23th day of October, 2007



Michael J. Vilbert
Principal
The Brattle Group

APPENDIX A

RESUME

MICHAEL J. VILBERT **PRINCIPAL**

Michael Vilbert is an expert in cost of capital, financial planning and valuation who has advised clients on these matters in the context of a wide variety of investment and regulatory decisions. He received his Ph.D. in Financial Economics from the Wharton School of the University of Pennsylvania, an MBA from the University of Utah, an M.S. from the Fletcher School of Law and Diplomacy, Tufts University, and a B.S. degree from the United States Air Force Academy. He joined The Brattle Group in 1994 after a career as an Air Force officer, where he served as a fighter pilot, intelligence officer, and professor of finance at the Air Force Academy.

REPRESENTATIVE CONSULTING EXPERIENCE

- In a securities fraud case, Dr. Vilbert designed and created a model to value the private placement stock of a drug store chain as if there had been full disclosure of the actual financial condition of the firm. He analyzed key financial data and security analysts' reports regarding the future of the industry in order to recreate pro forma balance sheet and income statements under a variety of scenarios designed to establish the value of the firm.

- For pharmaceutical companies rebutting price-fixing claims in antitrust litigation, Dr. Vilbert was a member of a team that prepared a comprehensive analysis of industry profitability. The analysis replicated, tested and critiqued the major recent analyses of drug costs, risks and returns. The analyses helped develop expert witness testimony to rebut allegations of excess profits.

- For an independent electric power producer, Dr. Vilbert created a model that analyzed the reasonableness of rates and costs filed by a natural gas pipeline. The model not only duplicated the pipeline's rates, but it also allowed simulation of a variety of "what if" scenarios associated with cost recovery under alternative time patterns and joint cost allocations. Results of the analysis were adopted by the intervenor group for negotiation with the pipeline.

- For the CFO of an electric utility, Dr. Vilbert developed the valuation model used to support a stranded cost estimation filing. The case involved a conflict between two utilities over the responsibility for out-of-market costs associated with a power purchase contract between them. In addition, he advised and analyzed cost recovery mechanisms

that would allow full recovery of the stranded costs while providing a rate reduction for the company's rate payers.

- Dr. Vilbert has testified as well as assisted in the preparation of testimony and the development of estimation models in numerous cost of capital cases for natural gas pipeline, water utility and electric utility clients before the Federal Energy Regulatory Commission ("FERC") and state regulatory commissions. These have spanned standard estimation techniques (e.g., Discounted Cash Flow and Risk Positioning models). He has also developed and applied more advanced models specific to the industries or lines of business in question, e.g., based on the structure and risk characteristics of cash flows, or based on multi-factor models that better characterize regulated industries.

- Dr. Vilbert has valued several large, residual oil-fired generating stations to evaluate the possible conversion to natural gas or other fuels. In these analyses, the expected pre- and post-conversion station values were computed using a range of market electricity and fuel cost conditions.

- For a major western electric utility, Dr. Vilbert helped prepare testimony that analyzed the prudence of QF contract enforcement. The testimony demonstrated that the utility had not been compensated in its allowed cost of capital for major disallowances stemming from QF contract management.

- Dr. Vilbert analyzed the economic need for a major natural gas pipeline expansion to the Midwest. This involved evaluating forecasts of natural gas use in various regions of the United States and the effect of additional supplies on the pattern of natural gas pipeline use. The analysis was used to justify the expansion before the FERC and the National Energy Board of Canada.

- For a Public Utility Commission in the Northeast, Dr. Vilbert analyzed the auction of an electric utility's purchase power agreements to determine whether the outcome of the auction was in the ratepayers' interest. The work involved the analysis of the auction procedures as well as the benefits to ratepayers of transferring risk of the PPA payments to the buyer.

- Dr. Vilbert led a team tasked to determine whether bridge tolls were "just and reasonable" for a non-profit port authority. Determination of the cost of service for the authority required estimation of the value of the authority's assets using the trended original cost methodology as well as evaluation of the operations and maintenance budgets. Investment costs, bridge traffic information and inflation indices covering a 75 year period were utilized to estimate the value of four bridges and a passenger transit line valued in excess of $1 billion.

- Dr. Vilbert helped a recently privatized railroad in Brazil develop an estimate of its revenue requirements, including a determination of the railroad's cost of capital. He also helped evaluate alternative rate structures designed to provide economic incentives to shippers as well as to the railroad for improved service. This involved the explanation

and analysis of the contribution margin of numerous shipper products, improved cost analysis and evaluation of bottlenecks in the system.

- For a utility in the Southeast, Dr. Vilbert quantified the company's stranded costs under several legislative electric restructuring scenarios. This involved the evaluation of all of the company's fossil and nuclear generating units, its contracts with Qualifying Facilities and the prudence of those QF contracts. He provided analysis concerning the impact of securitizing the company's stranded costs as a means of reducing the cost to the ratepayers and several alternative designs for recovering stranded costs.

- For a recently privatized electric utility in Australia, Dr. Vilbert evaluated the proposed regulatory scheme of the Australian Competition and Consumer Commission for the company's electric transmission system. The evaluation highlighted the elements of the proposed regulation which would impose uncompensated asymmetric risks on the company and the need to either eliminate the asymmetry in risk or provide additional compensation so that the company could expect to earn its cost of capital.

- For an electric utility in the Southwest, Dr. Vilbert helped design and create a model to estimate the stranded costs of the company's portfolio of Qualifying Facilities and Power Purchase contracts. This exercise was complicated by the many variations in the provisions of the contracts that required modeling in order to capture the effect of changes in either the performance of the plants or in the estimated market price of electricity.

- Dr. Vilbert helped prepare the testimony responding to a FERC request for further comments on the appropriate return on equity for electric transmission facilities. In addition, Dr. Vilbert was a member of the team that made a presentation to the FERC staff on the expected risks of the unbundled electric transmission line of business.

- Dr. Vilbert and Mr. Frank C. Graves, also of The Brattle Group, prepared testimony evaluating an innovative Canadian stranded cost recovery procedure involving the auctioning of the output of the province's electric generation plants instead of the plants themselves. The evaluation required the analysis of the terms and conditions of the long-term contracts specifying the revenue requirements of the plants for their entire forecasted remaining economic life and required an estimate of the cost of capital for the plant owners under this new stranded cost recovery concept.

- Dr. Vilbert served as the neutral arbitrator for the valuation of a petroleum products tanker. The valuation required analysis of the Jones Act tanker market and the supply and demand balance of the available U.S. constructed tanker fleet.

TESTIMONY

Direct and rebuttal testimony before the Alberta Energy and Utilities Board on behalf of TransAlta Utilities Corporation in the matter of an application for approval of its 1999 and 2000 generation tariff, transmission tariff, and distribution revenue requirement, October 1998.

Direct testimony before the Federal Energy Regulatory Commission on behalf of Central Maine Power in Docket No. ER00-982-000, December 1999.

Direct testimony before the Alberta Energy and Utilities Board on behalf of TransAlta Utilities Corporation for approval of its 2001 transmission tariff, May 2000.

Direct testimony before the Federal Energy Regulatory Commission on behalf of Mississippi River Transmission Corporation in Docket No. RP01-292-000, March 2001.

Written evidence, rebuttal, reply and further reply before the National Energy Board in the matter of an application by TransCanada PipeLines Limited for orders pursuant to Part I and Part IV of the *National Energy Board Act*, Order AO-1-RH-4-2001, May 2001, Nov. 2001, Feb. 2002.

Written evidence before the Public Utility Board on behalf of Newfoundland & Labrador Hydro - Rate Hearings, October 2001.

Direct testimony (with William Lindsay) before the Federal Energy Regulatory Commission on behalf of DTE East China, LLC in Docket No. ER02-1599-000, April 2002.

Direct and rebuttal reports before the Arbitration Panel in the arbitration of stranded costs for the City of Casselberry, FL, Case No. 00-CA-1107-16-L, July 2002.

Direct reports before the Arbitration Board for Petroleum products trade in the Arbitration of the Military Sealift Command vs. Household Commercial Financial Services, fair value of sale of the Darnell, October 2002.
