The excess benefit tax is imposed on the disqualified person and, in certain cases, on the organization manager, but is not imposed on the exempt organization. An initial tax of 25 percent of the excess benefit amount is imposed on the disqualified person that receives the excess benefit. An additional tax on the disqualified person of 200 percent of the excess benefit applies if the violation is not corrected. A tax of 10 percent of the excess benefit (not to exceed $10,000 with respect to any excess benefit transaction) is imposed on an organization manager that knowingly participated in the excess benefit transaction, if the manager's participation was willful and not due to reasonable cause, and if the initial tax was imposed on the disqualified person.[327] If more than one person is liable for the tax on disqualified persons or on management, all such persons are jointly and severally liable for the tax.[328]

Private foundations

Self-dealing by private foundations

Excise taxes are imposed on acts of self-dealing between a disqualified person (as defined in section 4946) and a private foundation.[329] In general, self-dealing transactions are any direct or indirect: (1) sale or exchange, or leasing, of property between a private foundation and a disqualified person; (2) lending of money or other extension of credit between a private foundation and a disqualified person; (3) the furnishing of goods, services, or facilities between a private foundation and a disqualified person; (4) the payment of compensation (or payment or reimbursement of expenses) by a private foundation to a disqualified person; (5) the transfer to, or use by or for the benefit of, a disqualified person of the income or assets of the private foundation; and (6) certain payments of money or property to a government official.[330] Certain exceptions apply.[331]

---

[326] Sec. 4958. The excess benefit transaction tax commonly is referred to as "intermediate sanctions," because it imposes penalties generally considered to be less punitive than revocation of the organization's exempt status.

[327] Sec. 4958(d)(2). Taxes imposed may be abated if certain conditions are met. Secs. 4961 and 4962.

[328] Sec. 4958(d)(1).

[329] Sec. 4941.

[330] Sec. 4941(d)(1).

[331] See sec. 4941(d)(2).

An initial tax of five percent of the amount involved with respect to an act of self-dealing is imposed on any disqualified person (other than a foundation manager acting only as such) who participates in the act of self-dealing. If such a tax is imposed, a 2.5-percent tax of the amount involved is imposed on a foundation manager who participated in the act of self-dealing knowing it was such an act (and such participation was not willful and was due to reasonable cause) up to $10,000 per act. Such initial taxes may not be abated.[332] Such initial taxes are imposed for each year in the taxable period, which begins on the date the act of self-dealing occurs and ends on the earliest of the date of mailing of a notice of deficiency for the tax, the date on which the tax is assessed, or the date on which correction of the act of self-dealing is completed. A government official (as defined in section 4946(c)) is subject to such initial tax only if the official participates in the act of self-dealing knowing it is such an act. If the act of self-dealing is not corrected, a tax of 200 percent of the amount involved is imposed on the disqualified person and a tax of 50 percent of the amount involved (up to $10,000 per act) is imposed on a foundation manager who refused to agree to correcting the act of self-dealing. Such additional taxes are subject to abatement.[333]

Tax on failure to distribute income

Private nonoperating foundations are required to pay out a minimum amount each year as qualifying distributions. In general, a qualifying distribution is an amount paid to accomplish one or more of the organization's exempt purposes, including reasonable and necessary administrative expenses.[334] Failure to pay out the minimum results in an initial excise tax on the foundation of 15 percent of the undistributed amount. An additional tax of 100 percent of the undistributed amount applies if an initial tax is imposed and the required distributions have not been made by the end of the applicable taxable period.[335] A foundation may include as a qualifying distribution the salaries, occupancy expenses, travel costs, and other reasonable and necessary administrative expenses that the foundation incurs in operating a grant program. A qualifying distribution also includes any amount paid to acquire an asset used (or held for use) directly in carrying out one or more of the organization's exempt purposes and certain amounts set-aside for exempt purposes.[336] Private operating foundations are not subject to the payout requirements.

---

[332] Sec. 4962(b).

[333] Sec. 4961.

[334] Sec. 4942(g)(1)(A).

[335] Sec. 4942(a) and (b). Taxes imposed may be abated if certain conditions are met. Secs. 4961 and 4962.

[336] Sec. 4942(g)(1)(B) and 4942(g)(2). In general, an organization is permitted to adjust the distributable amount in those cases where distributions during the five preceding years have exceeded the payout requirements. Sec. 4942(i).

Tax on excess business holdings

Private foundations are subject to tax on excess business holdings.[337] In general, a private foundation is permitted to hold 20 percent of the voting stock in a corporation, reduced by the amount of voting stock held by all disqualified persons (as defined in section 4946). If it is established that no disqualified person has effective control of the corporation, a private foundation and disqualified persons together may own up to 35 percent of the voting stock of a corporation. A private foundation shall not be treated as having excess business holdings in any corporation if it owns (together with certain other related private foundations) not more than two percent of the voting stock and not more than two percent in value of all outstanding shares of all classes of stock in that corporation. Similar rules apply with respect to holdings in a partnership ("profits interest" is substituted for "voting stock" and "capital interest" for "nonvoting stock") and to other unincorporated enterprises (by substituting "beneficial interest" for "voting stock"). Private foundations are not permitted to have holdings in a proprietorship. Foundations generally have a five-year period to dispose of excess business holdings (acquired other than by purchase) without being subject to tax.[338] This five-year period may be extended an additional five years in limited circumstances.[339] The excess business holdings rules do not apply to holdings in a functionally related business or to holdings in a trade or business at least 95 percent of the gross income of which is derived from passive sources.[340]

The initial tax is equal to five percent of the value of the excess business holdings held during the foundation's applicable taxable year. An additional tax is imposed if an initial tax is imposed and at the close of the applicable taxable period, the foundation continues to hold excess business holdings. The amount of the additional tax is equal to 200 percent of such holdings.

Tax on jeopardizing investments

Private foundations and foundation managers are subject to tax on investments that jeopardize the foundation's charitable purpose.[341] In general, an initial tax of five percent of the amount of the investment applies to the foundation and to foundation managers who participated in the making of the investment knowing that it jeopardized the carrying out of the foundation's exempt purposes. The initial tax on foundation managers may not exceed $5,000 per investment. If the investment is not removed from jeopardy (e.g., sold or otherwise disposed of), an additional tax of 25 percent of the amount of the investment is imposed on the foundation and five percent of the amount of the investment on a foundation manager who refused to agree to removing the investment from jeopardy. The additional tax on foundation managers may not exceed $10,000 per investment. An investment, the primary purpose of which is to accomplish a

charitable purpose and no significant purpose of which is the production of income or the appreciation of property, is not considered a jeopardizing investment.[342]

Tax on taxable expenditures

Certain expenditures of private foundations are subject to tax.[343] In general, taxable expenditures are expenses: (1) for lobbying; (2) to influence the outcome of a public election or carry on a voter registration drive (unless certain requirements are met); (3) as a grant to an individual for travel, study, or similar purposes unless made pursuant to procedures approved by the Secretary; (4) as a grant to an organization that is not a public charity or exempt operating foundation unless the foundation exercises expenditure responsibility[344] with respect to the grant; or (5) for any non-charitable purpose. For each taxable expenditure, a tax is imposed on the foundation of 10 percent of the amount of the expenditure, and an additional tax of 100 percent is imposed on the foundation if the expenditure is not corrected. A tax of 2.5 percent of the expenditure (up to $5,000) also is imposed on a foundation manager who agrees to making a taxable expenditure knowing that it is a taxable expenditure. An additional tax of 50 percent of the amount of the expenditure (up to $10,000) is imposed on a foundation manager who refuses to agree to correction of such expenditure.

Explanation of Provision

Self-dealing and excess benefit transaction initial taxes and dollar limitations

For acts of self-dealing by a private foundation to a disqualified person, the provision increases the initial tax on the self-dealer from five percent of the amount involved to 10 percent of the amount involved. The provision increases the initial tax on foundation managers from 2.5 percent of the amount involved to five percent of the amount involved and increases the dollar limitation on the amount of the initial and additional taxes on foundation managers per act of self-dealing from $10,000 per act to $20,000 per act. Similarly, the provision doubles the dollar limitation on organization managers of public charities and social welfare organizations for participation in excess benefit transactions from $10,000 per transaction to $20,000 per transaction.

Failure to distribute income, excess business holdings, jeopardizing investments, and taxable expenditures

The provision doubles the amounts of the initial taxes and the dollar limitations on foundation managers with respect to the private foundation excise taxes on the failure to distribute income, excess business holdings, jeopardizing investments, and taxable expenditures.

---

[342] Sec. 4944(c).

[343] Sec. 4945. Taxes imposed may be abated if certain conditions are met. Secs. 4961 and 4962.

[344] In general, expenditure responsibility requires that a foundation make all reasonable efforts and establish reasonable procedures to ensure that the grant is spent solely for the purpose for which it was made, to obtain reports from the grantee on the expenditure of the grant, and to make reports to the Secretary regarding such expenditures. Sec. 4945(h).

Specifically, for the failure to distribute income, the initial tax on the foundation is increased from 15 percent of the undistributed amount to 30 percent of the undistributed amount.

For excess business holdings, the initial tax on excess business holdings is increased from five percent of the value of such holdings to 10 percent of such value.

For jeopardizing investments, the initial tax of five percent of the amount of the investment that is imposed on the foundation and on foundation managers is increased to 10 percent of the amount of the investment. The dollar limitation on the initial tax on foundation managers of $5,000 per investment is increased to $10,000 and the dollar limitation on the additional tax on foundation managers of $10,000 per investment is increased to $20,000.

For taxable expenditures, the initial tax on the foundation is increased from 10 percent of the amount of the expenditure to 20 percent, the initial tax on the foundation manager is increased from 2.5 percent of the amount of the expenditure to five percent, the dollar limitation on the initial tax on foundation managers is increased from $5,000 to $10,000, and the dollar limitation on the additional tax on foundation managers is increased from $10,000 to $20,000.

Effective Date

The provision is effective for taxable years beginning after the date of enactment.

3. Reform rules for charitable contributions of easements in registered historic districts and take account of rehabilitation credit in easement donations (sec. 170 of the Code)

Present Law

In general

Present law provides special rules that apply to charitable deductions of qualified conservation contributions, which include conservation easements and façade easements.[345] Qualified conservation contributions are not subject to the "partial interest" rule, which generally bars deductions for charitable contributions of partial interests in property.[346] Accordingly, qualified conservation contributions are contributions of partial interests that are eligible for a fair market value charitable deduction.

A qualified conservation contribution is a contribution of a qualified real property interest to a qualified organization exclusively for conservation purposes. A qualified real property interest is defined as: (1) the entire interest of the donor other than a qualified mineral interest; (2) a remainder interest; or (3) a restriction (granted in perpetuity) on the use that may be made

[345] Sec. 170(h).

[346] Sec. 170(f)(3).

of the real property.[347] Qualified organizations include certain governmental units, public charities that meet certain public support tests, and certain supporting organizations.

Conservation purposes include: (1) the preservation of land areas for outdoor recreation by, or for the education of, the general public; (2) the protection of a relatively natural habitat of fish, wildlife, or plants, or similar ecosystem; (3) the preservation of open space (including farmland and forest land) where such preservation will yield a significant public benefit and is either for the scenic enjoyment of the general public or pursuant to a clearly delineated Federal, State, or local governmental conservation policy; and (4) the preservation of an historically important land area or a certified historic structure.[348]

In general, no deduction is available if the property may be put to a use that is inconsistent with the conservation purpose of the gift.[349] A contribution is not deductible if it accomplishes a permitted conservation purpose while also destroying other significant conservation interests.[350]

Taxpayers are required to obtain a qualified appraisal for donated property with a value of $5,000 or more, and to attach an appraisal summary to the tax return.[351] Under Treasury regulations, a qualified appraisal means an appraisal document that, among other things: (1) relates to an appraisal that is made not earlier than 60 days prior to the date of contribution of the appraised property and not later than the due date (including extensions) of the return on which a deduction is first claimed under section 170;[352] (2) is prepared, signed, and dated by a qualified appraiser; (3) includes (a) a description of the property appraised; (b) the fair market value of such property on the date of contribution and the specific basis for the valuation; (c) a statement that such appraisal was prepared for income tax purposes; (d) the qualifications of the qualified appraiser; and (e) the signature and taxpayer identification number of such appraiser; and (4) does not involve an appraisal fee that violates certain prescribed rules.[353]

---

[347] Charitable contributions of interests that constitute the taxpayer's entire interest in the property are not regarded as qualified real property interests within the meaning of section 170(h), but instead are subject to the general rules applicable to charitable contributions of entire interests of the taxpayer (i.e., generally are deductible at fair market value, without regard to satisfaction of the requirements of section 170(h)).

[348] Sec. 170(h)(4)(A).

[349] Treas. Reg. sec. 1.170A-14(e)(2).

[350] Treas. Reg. sec. 1.170A-14(e)(2).

[351] Sec. 170(f)(11)(C).

[352] In the case of a deduction first claimed or reported on an amended return, the deadline is the date on which the amended return is filed.

[353] Treas. Reg. sec. 1.170A-13(c)(3).

Valuation

The value of a conservation restriction granted in perpetuity generally is determined under the "before and after approach." Such approach provides that the fair market value of the restriction is equal to the difference (if any) between the fair market value of the property the restriction encumbers before the restriction is granted and the fair market value of the encumbered property after the restriction is granted.[354]

If the granting of a perpetual restriction has the effect of increasing the value of any other property owned by the donor or a related person, the amount of the charitable deduction for the conservation contribution is to be reduced by the amount of the increase in the value of the other property.[355] In addition, the donor is to reduce the amount of the charitable deduction by the amount of financial or economic benefits that the donor or a related person receives or can reasonably be expected to receive as a result of the contribution.[356] If such benefits are greater than those that will inure to the general public from the transfer, no deduction is allowed.[357] In those instances where the grant of a conservation restriction has no material effect on the value of the property, or serves to enhance, rather than reduce, the value of the property, no deduction is allowed.[358]

Preservation of a certified historic structure

A certified historic structure means any building, structure, or land which is (i) listed in the National Register, or (ii) located in a registered historic district (as defined in section 47(c)(3)(B)) and is certified by the Secretary of the Interior to the Secretary of the Treasury as being of historic significance to the district.[359] For this purpose, a structure means any structure, whether or not it is depreciable, and, accordingly, easements on private residences may qualify.[360] If restrictions to preserve a building or land area within a registered historic district permit future development on the site, a deduction will be allowed only if the terms of the restrictions require that such development conform with appropriate local, State, or Federal standards for construction or rehabilitation within the district.[361]

[360] Treas. Reg. sec. 1.170A-14(d)(5)(iii).

[361] Treas. Reg. sec. 1.170A-14(d)(5)(i).

The IRS and the courts have held that a facade easement may constitute a qualifying conservation contribution.[362] In general, a facade easement is a restriction the purpose of which is to preserve certain architectural, historic, and cultural features of the facade, or front, of a building. The terms of a facade easement might permit the property owner to make alterations to the facade of the structure if the owner obtains consent from the qualified organization that holds the easement.

Rehabilitation credit

In general, present law allows as part of the general business credit an investment tax credit.[363] The amount of the investment tax credit includes the amount of a rehabilitation credit.[364] The rehabilitation credit for any taxable year is the sum of ten percent of the qualified rehabilitation expenditures with respect to any qualified rehabilitated building other than a certified historic structure and 20 percent of the qualified rehabilitation expenditures with respect to any certified historic structure.[365] In general, a qualified rehabilitated building is a depreciable building (and its structural components) if the building has been substantially rehabilitated, was placed in service before the beginning of the rehabilitation, and (except for a certified historic structure) in the rehabilitation process a certain percentage of the existing internal and external walls and internal structural framework are retained in place as internal and external walls and internal structural framework. A qualified rehabilitation expenditure is, in general, an amount properly chargeable to a capital account (i) for depreciable property that is nonresidential real property, residential rental property, real property that has a class life of more than 12.5 years, or an addition or improvement to any such property and (ii) in connection with the rehabilitation of a qualified rehabilitation building.

Explanation of Provision

Easements in registered historic districts

The provision revises the rules for qualified conservation contributions with respect to property for which a charitable deduction is allowable under section 170(h)(4)(B)(ii) by reason of a property's location in a registered historic district. Under the provision, a charitable deduction is not allowable with respect to a structure or land area located in such a district (by reason of the structure or land area's location in such a district). A charitable deduction is

---

[362] *Hillborn v. Commissioner*, 85 T.C. 677 (1985) (holding the fair market value of a facade donation generally is determined by applying the "before and after" valuation approach); *Richmond v. U.S.*, 699 F. Supp. 578 (E.D. La. 1988); Priv. Ltr. Rul. 199933029 (May 24, 1999) (ruling that a preservation and conservation easement relating to the facade and certain interior portions of a fraternity house was a qualified conservation contribution).

[363] Sec. 38(b)(1).

[364] Sec. 46.

[365] Sec. 47(a).

allowable with respect to buildings (as is the case under present law) but the qualified real property interest that relates to the exterior of the building must preserve the entire exterior of the building, including the space above the building, the sides, the rear, and the front of the building. In addition, such qualified real property interest must provide that no portion of the exterior of the building may be changed in a manner inconsistent with the historical character of such exterior.

For any contribution relating to a registered historic district made after the date of enactment of the provision, taxpayers must include with the return for the taxable year of the contribution a qualified appraisal of the qualified real property interest (irrespective of the claimed value of such interest) and attach the appraisal with the taxpayer's return, photographs of the entire exterior of the building,[366] and descriptions of all current restrictions on development of the building, including, for example, zoning laws, ordinances, neighborhood association rules, restrictive covenants, and other similar restrictions. Failure to obtain and attach an appraisal or to include the required information results in disallowance of the deduction. In addition, the donor and the donee must enter into a written agreement certifying, under penalty of perjury, that the donee is a qualified organization, with a purpose of environmental protection, land conservation, open space preservation, or historic preservation, and that the donee has the resources to manage and enforce the restriction and a commitment to do so.

Taxpayers claiming a deduction for a qualified conservation contribution with respect to the exterior of a building located in a registered historic district in excess of $10,000 must pay a $500 fee to the Internal Revenue Service or the deduction is not allowed. Amounts paid are required to be dedicated to Internal Revenue Service enforcement of qualified conservation contributions.

Reduction of deduction to take account of rehabilitation credit

The provision provides that in the case of any qualified conservation contribution, the amount of the deduction is reduced by an amount that bears the same ratio to the fair market value of the contribution as the sum of the rehabilitation credits under section 47 for the preceding five taxable years with respect to a building that is part of the contribution bears to the fair market value of the building on the date of the contribution. For example, if a taxpayer makes a qualified conservation contribution with respect to a building, and such taxpayer has claimed a rehabilitation credit with respect to such building in any of the five taxable years preceding the year in which the contribution is claimed, the taxpayer must reduce the amount of the contribution. If the aggregate amount of credits claimed by the taxpayer within such five year period is $100,000, and the fair market value of the building with respect to which the contribution is made is $1,000,000, the taxpayer must reduce the amount of the deduction by 10 percent (or 100,000 over 1,000,000).

[366] Photographs of the entire exterior of the building are required to the extent practicable. For example, if the building is a skyscraper, aerial photographs of the roof would not be required, but photographs sufficient to establish the existing exterior still must be submitted.

Effective Date

The provisions relating to deductions for contributions relating to structures and land areas and to the rehabilitation credit are effective for contributions made after the date of enactment. The provision relating to a filing fee is effective for contributions made 180 days after the date of enactment. The rest of the provision is effective for contributions made after July 25, 2006.

4. Reform rules relating to charitable contributions of taxidermy (sec. 170 of the Code)

Present Law

In computing taxable income, a taxpayer who itemizes deductions generally is allowed to deduct the amount of cash and the fair market value of property contributed to an organization described in section 501(c)(3) or to a Federal, State, or local governmental entity.[367] The amount of the deduction allowable for a taxable year with respect to a charitable contribution of property may be reduced or limited depending on the type of property contributed, the type of charitable organization to which the property is contributed, and the income of the taxpayer.[368] In general, more generous charitable contribution deduction rules apply to gifts made to public charities than to gifts made to private foundations. Within certain limitations, donors also are entitled to deduct their contributions to section 501(c)(3) organizations for Federal estate and gift tax purposes. By contrast, contributions to nongovernmental, non-charitable tax-exempt organizations generally are not deductible by the donor,[369] though such organizations are eligible for the exemption from Federal income tax with respect to such donations.

The amount of the deduction for charitable contributions of capital gain property generally equals the fair market value of the contributed property on the date of the contribution. Capital gain property means any capital asset, or property used in the taxpayer's trade or business, the sale of which at its fair market value, at the time of contribution, would have resulted in gain that would have been long-term capital gain. Contributions of capital gain property are subject to different percentage limitations (i.e., limitations based on the donor's income) than other contributions of property.

For certain contributions of property, the deductible amount is reduced from the fair market value of the contributed property by the amount of any gain, generally resulting in a

[367] The deduction also is allowed for purposes of calculating alternative minimum taxable income.

[368] Secs. 170(b) and (e).

[369] Exceptions to the general rule of non-deductibility include certain gifts made to a veterans' organization or to a domestic fraternal society. In addition, contributions to certain nonprofit cemetery companies are deductible for Federal income tax purposes, but generally are not deductible for Federal estate and gift tax purposes. Secs. 170(c)(3), 170(c)(4), 170(c)(5), 2055(a)(3), 2055(a)(4), 2106(a)(2)(A)(iii), 2522(a)(3), and 2522(a)(4).

deduction equal to the taxpayer's basis. This rule applies to contributions of: (1) ordinary income property, e.g., property that, at the time of contribution, would not have resulted in long-term capital gain if the property was sold by the taxpayer on the contribution date;[370] (2) tangible personal property that is used by the donee in a manner unrelated to the donee's exempt (or governmental) purpose; and (3) property to or for the use of a private foundation (other than a foundation defined in section 170(b)(1)(E)).

Charitable contributions of taxidermy are subject to the tangible personal property rule (number (2) above). For example, for appreciated taxidermy, if the property is used to further the donee's exempt purpose, the deduction is fair market value. But if the property is not used to further the donee's exempt purpose, the deduction is the donor's basis. If the taxidermy is depreciated, i.e., the value is less than the taxpayer's basis in such property, taxpayers generally deduct the fair market value of such contributions, regardless of whether the property is used for exempt or unrelated purposes by the donee.

Explanation of Provision

In general, the provision provides that the amount allowed as a deduction for charitable contributions of taxidermy property that is contributed by the person who prepared, stuffed, or mounted the property (or by any person who paid or incurred the cost of such preparation, stuffing, or mounting) is the lesser of the taxpayer's basis in the property or the fair market value of the property. Specifically, a taxpayer that makes such a charitable contribution of taxidermy property for a use related to the donee's exempt purpose or function must, in determining the amount of the deduction, reduce the fair market value of the property by the amount of gain that would have been long-term capital gain if the property contributed had been sold by the taxpayer at its fair market value (determined at the time of the contribution). Taxidermy property is defined as any work of art that is the reproduction or preservation of an animal in whole or in part, is prepared, stuffed or mounted for purposes of recreating one or more characteristics of such animal, and contains a part of the body of the dead animal.

For purposes of determining a taxpayer's basis in taxidermy property that is contributed by the person who prepared, stuffed, or mounted the property (or by any person who paid or incurred the cost of such preparation, stuffing, or mounting), the provision provides a special rule that the basis of such property may include only the cost of the preparing, stuffing, or mounting. For purposes of the special rule, it is intended that only the direct costs of the preparing, stuffing, or mounting may be included in basis. Indirect costs, not included in the basis, include the costs of transportation relating to any aspect of the taxidermy or the hunting of the animal, and the direct or indirect costs relating to the hunting or killing of an animal (including the cost of equipment and the costs of preparing an animal carcass for taxidermy).

---

[370] For certain contributions of inventory, C corporations may claim an enhanced deduction equal to the lesser of (1) basis plus one-half of the item's appreciation (i.e., basis plus one half of fair market value in excess of basis) or (2) two times basis. Sec. 170(e)(3), 170(e)(4), 170(e)(6).

Effective Date

The provision is effective for contributions made after July 25, 2006.

5. Recapture of tax benefit on property not used for an exempt use (new sec. 6720B of the Code)

Present Law

Deductibility of charitable contributions

In general

In computing taxable income, a taxpayer who itemizes deductions generally is allowed to deduct the amount of cash and the fair market value of property contributed to an organization described in section 501(c)(3) or to a Federal, State, or local governmental entity.[371] The amount of the deduction allowable for a taxable year with respect to a charitable contribution of property may be reduced or limited depending on the type of property contributed, the type of charitable organization to which the property is contributed, and the income of the taxpayer.[372] In general, more generous charitable contribution deduction rules apply to gifts made to public charities than to gifts made to private foundations. Within certain limitations, donors also are entitled to deduct their contributions to section 501(c)(3) organizations for Federal estate and gift tax purposes. By contrast, contributions to nongovernmental, non-charitable tax-exempt organizations generally are not deductible by the donor,[373] though such organizations are eligible for the exemption from Federal income tax with respect to such donations.

Contributions of property

The amount of the deduction for charitable contributions of capital gain property generally equals the fair market value of the contributed property on the date of the contribution. Capital gain property means any capital asset, or property used in the taxpayer's trade or business, the sale of which at its fair market value, at the time of contribution, would have resulted in gain that would have been long-term capital gain. Contributions of capital gain property are subject to different percentage limitations (i.e., limitations based on the donor's income) than other contributions of property.

---

[371] The deduction also is allowed for purposes of calculating alternative minimum taxable income.

[372] Secs. 170(b) and (e).

[373] Exceptions to the general rule of non-deductibility include certain gifts made to a veterans' organization or to a domestic fraternal society. In addition, contributions to certain nonprofit cemetery companies are deductible for Federal income tax purposes, but generally are not deductible for Federal estate and gift tax purposes. Secs. 170(c)(3), 170(c)(4), 170(c)(5), 2055(a)(3), 2055(a)(4), 2106(a)(2)(A)(iii), 2522(a)(3), and 2522(a)(4).

For certain contributions of property, the deductible amount is reduced from the fair market value of the contributed property by the amount of any gain, generally resulting in a deduction equal to the taxpayer's basis. This rule applies to contributions of: (1) ordinary income property, e.g., property that, at the time of contribution, would not have resulted in long-term capital gain if the property was sold by the taxpayer on the contribution date;[374] (2) tangible personal property that is used by the donee in a manner unrelated to the donee's exempt (or governmental) purpose; and (3) property to or for the use of a private foundation (other than a foundation defined in section 170(b)(1)(E)).

Substantiation

No charitable deduction is allowed for any contribution of $250 or more unless the taxpayer substantiates the contribution by a contemporaneous written acknowledgement of the contribution by the donee organization.[375] Such acknowledgement must include the amount of cash and a description (but not value) of any property other than cash contributed, whether the donee provided any goods or services in consideration for the contribution (and a good faith estimate of the value of any such goods or services).

In general, if the total charitable deduction claimed for non-cash property is more than $500, the taxpayer must attach a completed Form 8283 (Noncash Charitable Contributions) to the taxpayer's return or the deduction is not allowed.[376] C corporations (other than personal service corporations and closely-held corporations) are required to file Form 8283 only if the deduction claimed is more than $5,000. Information required on the Form 8283 includes, among other things, a description of the property, the appraised fair market value (if an appraisal is required), the donor's basis in the property, how the donor acquired the property, a declaration by the appraiser regarding the appraiser's general qualifications, an acknowledgement by the donee that it is eligible to receive deductible contributions, and an indication by the donee whether the property is intended for an unrelated use.

Taxpayers are required to obtain a qualified appraisal for donated property with a value of more than $5,000, and to attach an appraisal summary to the tax return.[377] Under Treasury regulations, a qualified appraisal means an appraisal document that, among other things: (1) relates to an appraisal that is made not earlier than 60 days prior to the date of contribution of the appraised property and not later than the due date (including extensions) of the return on which a

[374] For certain contributions of inventory, C corporations may claim an enhanced deduction equal to the lesser of (1) basis plus one-half of the item's appreciation (i.e., basis plus one half of fair market value in excess of basis) or (2) two times basis. Sec. 170(e)(3), 170(e)(4), 170(e)(6).

[375] Sec. 170(f)(8).

[376] Sec. 170(f)(11).

[377] *Id.*

deduction is first claimed under section 170;[378] (2) is prepared, signed, and dated by a qualified appraiser; (3) includes (a) a description of the property appraised; (b) the fair market value of such property on the date of contribution and the specific basis for the valuation; (c) a statement that such appraisal was prepared for income tax purposes; (d) the qualifications of the qualified appraiser; and (e) the signature and taxpayer identification number of such appraiser; and (4) does not involve an appraisal fee that violates certain prescribed rules.[379] In the case of contributions of art valued at more than $20,000 and other contributions of more than $500,000, taxpayers are required to attach the appraisal to the tax return. Taxpayers may request a Statement of Value from the Internal Revenue Service in order to substantiate the value of art with an appraised value of $50,000 or more for income, estate, or gift tax purposes.[380] The fee for such a Statement is $2,500 for one, two, or three items or art plus $250 for each additional item.

If a donee organization sells, exchanges, or otherwise disposes of contributed property with a claimed value of more than $5,000 (other than publicly traded securities) within two years of the property's receipt, the donee is required to file a return (Form 8282) with the Secretary, and to furnish a copy of the return to the donor, showing the name, address, and taxpayer identification number of the donor, a description of the property, the date of the contribution, the amount received on the disposition, and the date of the disposition.[381]

Explanation of Provision

In general, the provision recovers the tax benefit for charitable contributions of tangible personal property with respect to which a fair market value deduction is claimed and which is not used for exempt purposes. The provision applies to appreciated tangible personal property that is identified by the donee organization, for example on the Form 8283, as for a use related to the purpose or function constituting the donee's basis for tax exemption, and for which a deduction of more than $5,000 is claimed ("applicable property").[382]

Under the provision, if a donee organization disposes of applicable property within three years of the contribution of the property, the donor is subject to an adjustment of the tax benefit. If the disposition occurs in the tax year of the donor in which the contribution is made, the donor's deduction generally is basis and not fair market value.[383] If the disposition occurs in a

[378] In the case of a deduction first claimed or reported on an amended return, the deadline is the date on which the amended return is filed.

[379] Treas. Reg. sec. 1.170A-13(c)(3). Sec. 170(f)(11)(E).

[380] Rev. Proc. 96-15, 1996-1 C.B. 627.

[381] Sec. 6050L(a)(1).

[382] Present law rules continue to apply to any contribution of exempt use property for which a deduction of $5,000 or less is claimed.

[383] The disposition proceeds are regarded as relevant to a determination of fair market value.

subsequent year, the donor must include as ordinary income for its taxable year in which the disposition occurs an amount equal to the excess (if any) of (i) the amount of the deduction previously claimed by the donor as a charitable contribution with respect to such property, over (ii) the donor's basis in such property at the time of the contribution.

There is no adjustment of the tax benefit if the donee organization makes a certification to the Secretary, by written statement signed under penalties of perjury by an officer of the organization. The statement must either (1) certify that the use of the property by the donee was related to the purpose or function constituting the basis for the donee's exemption, and describe how the property was used and how such use furthered such purpose or function; or (2) state the intended use of the property by the donee at the time of the contribution and certify that such use became impossible or infeasible to implement. The organization must furnish a copy of the certification to the donor (for example, as part of the Form 8282, a copy of which is supplied to the donor).

A penalty of $10,000 applies to a person that identifies applicable property as having a use that is related to a purpose or function constituting the basis for the donee's exemption knowing that it is not intended for such a use.[384]

Reporting of exempt use property contributions

The provision modifies the present-law information return requirements that apply upon the disposition of contributed property by a charitable organization (Form 8282, sec. 6050L). The return requirement is extended to dispositions made within three years after receipt (from two years). The donee organization also must provide, in addition to the information already required to be provided on the return, a description of the donee's use of the property, a statement of whether use of the property was related to the purpose or function constituting the basis for the donee's exemption, and, if applicable, a certification of any such use (described above).

Effective Date

The provision is effective for contributions made and returns filed after September 1, 2006, and with respect to the penalty, for identifications made after the date of enactment.

[384] Other present-law penalties also may apply, such as the penalty for aiding and abetting the understatement of tax liability under section 6701.

6. Limit charitable deduction for contributions of clothing and household items (sec. 170 of the Code)

Present Law

In general

In computing taxable income, a taxpayer who itemizes deductions generally is allowed to deduct the amount of cash and the fair market value of property contributed to an organization described in section 501(c)(3) or to a Federal, State, or local governmental entity.[385] The amount of the deduction allowable for a taxable year with respect to a charitable contribution of property may be reduced or limited depending on the type of property contributed, the type of charitable organization to which the property is contributed, and the income of the taxpayer.[386] In general, more generous charitable contribution deduction rules apply to gifts made to public charities than to gifts made to private foundations. Within certain limitations, donors also are entitled to deduct their contributions to section 501(c)(3) organizations for Federal estate and gift tax purposes. By contrast, contributions to nongovernmental, non-charitable tax-exempt organizations generally are not deductible by the donor,[387] though such organizations are eligible for the exemption from Federal income tax with respect to such donations.

Contributions of property

The amount of the deduction for charitable contributions of capital gain property generally equals the fair market value of the contributed property on the date of the contribution. Capital gain property means any capital asset or property used in the taxpayer's trade or business the sale of which at its fair market value, at the time of contribution, would have resulted in gain that would have been long-term capital gain. Contributions of capital gain property are subject to different percentage limitations than other contributions of property.

For certain contributions of property, the deductible amount is reduced from the fair market value of the contributed property by the amount of any gain, generally resulting in a deduction equal to the taxpayer's basis. This rule applies to contributions of: (1) ordinary income property, e.g., property that, at the time of contribution, would not have resulted in long-

[385] The deduction also is allowed for purposes of calculating alternative minimum taxable income.

[386] Secs. 170(b) and (e).

[387] Exceptions to the general rule of non-deductibility include certain gifts made to a veterans' organization or to a domestic fraternal society. In addition, contributions to certain nonprofit cemetery companies are deductible for Federal income tax purposes, but generally are not deductible for Federal estate and gift tax purposes. Secs. 170(c)(3), 170(c)(4), 170(c)(5), 2055(a)(3), 2055(a)(4), 2106(a)(2)(A)(iii), 2522(a)(3), and 2522(a)(4).

term capital gain if the property was sold by the taxpayer on the contribution date;[388] (2) tangible personal property that is used by the donee in a manner unrelated to the donee's exempt (or governmental) purpose; and (3) property to or for the use of a private foundation (other than a foundation defined in section 170(b)(1)(E)).

Charitable contributions of clothing and household items are subject to the tangible personal property rule (number (2) above). If such contributed property is appreciated property in the hands of the taxpayer, and is not used to further the donee's exempt purpose, the deduction is basis. In general, however, the value of clothing and household items is less than the taxpayer's basis in such property, with the result that taxpayers generally deduct the fair market value of such contributions, regardless of whether the property is used for exempt or unrelated purposes by the donee.

Substantiation

A donor who claims a deduction for a charitable contribution must maintain reliable written records regarding the contribution, regardless of the value or amount of such contribution. For a contribution of money, the donor generally must maintain one of the following: (1) a cancelled check; (2) a receipt (or a letter or other written communication) from the donee showing the name of the donee organization, the date of the contribution, and the amount of the contribution; or (3) in the absence of a cancelled check or a receipt, other reliable written records showing the name of the donee, the date of the contribution, and the amount of the contribution. For a contribution of property other than money, the donor generally must maintain a receipt from the donee organization showing the name of the donee, the date and location of the contribution, and a detailed description (but not the value) of the property.[389] A donor of property other than money need not obtain a receipt, however, if circumstances make obtaining a receipt impracticable. Under such circumstances, the donor must maintain reliable written records regarding the contribution. The required content of such a record varies depending upon factors such as the type and value of property contributed.[390]

In addition to the foregoing recordkeeping requirements, substantiation requirements apply in the case of charitable contributions with a value of $250 or more. No charitable deduction is allowed for any contribution of $250 or more unless the taxpayer substantiates the contribution by a contemporaneous written acknowledgement of the contribution by the donee organization. Such acknowledgement must include the amount of cash and a description (but not value) of any property other than cash contributed, whether the donee provided any goods or services in consideration for the contribution, and a good faith estimate of the value of any such

[388] For certain contributions of inventory and other property, C corporations may claim an enhanced deduction equal to the lesser of (1) basis plus one-half of the item's appreciation (i.e., basis plus one half of fair market value in excess of basis) or (2) two times basis. Sec. 170(e)(3), 170(e)(4), 170(e)(6).

[389] Treas. Reg. sec. 1.170A-13(a).

[390] Treas. Reg. sec. 1.170A-13(b).

goods or services.[391] In general, if the total charitable deduction claimed for non-cash property is more than $500, the taxpayer must attach a completed Form 8283 (Noncash Charitable Contributions) to the taxpayer's return or the deduction is not allowed.[392] In general, taxpayers are required to obtain a qualified appraisal for donated property with a value of more than $5,000, and to attach an appraisal summary to the tax return.

Explanation of Provision

The provision provides that no deduction is allowed for a charitable contribution of clothing or household items unless the clothing or household item is in good used condition or better. The Secretary is authorized to deny by regulation a deduction for any contribution of clothing or a household item that has minimal monetary value, such as used socks and used undergarments. It is noted that the President's Advisory Panel on Federal Tax Reform and the staff of the Joint Committee on Taxation both have concluded that the fair market value-based deduction for contributions of clothing and household items present difficult tax administration issues, as determining the correct value of an item is a fact intensive, and thus also a resource intensive matter.[393] As recently reported by the IRS, the amount claimed as deductions in tax year 2003 for clothing and household items was more than $9 billion.[394] It is expected that the Secretary, in consultation with affected charities, will exercise assiduously the authority to disallow a deduction for some items of low value, consistent with the goals of improving tax administration and ensure that donated clothing and households items are of meaningful use to charitable organizations.

Under the provision, a deduction may be allowed for a charitable contribution of an item of clothing or a household item not in good used condition or better if the amount claimed for the item is more than $500 and the taxpayer includes with the taxpayer's return a qualified appraisal with respect to the property. Household items include furniture, furnishings, electronics, appliances, linens, and other similar items. Food, paintings, antiques, and other objects of art, jewelry and gems, and collections are excluded from the provision.

Effective Date

The provision is effective for contributions made after the date of enactment.

7. Modify recordkeeping and substantiation requirements for certain charitable contributions (sec. 170 of the Code)

Present Law

A donor who claims a deduction for a charitable contribution must maintain reliable written records regarding the contribution, regardless of the value or amount of such contribution. For a contribution of money, the donor generally must maintain one of the following: (1) a cancelled check; (2) a receipt (or a letter or other written communication) from the donee showing the name of the donee organization, the date of the contribution, and the amount of the contribution; or (3) in the absence of a cancelled check or a receipt, other reliable written records showing the name of the donee, the date of the contribution, and the amount of the contribution. For a contribution of property other than money, the donor generally must maintain a receipt from the donee organization showing the name of the donee, the date and location of the contribution, and a detailed description (but not the value) of the property.[395] A donor of property other than money need not obtain a receipt, however, if circumstances make obtaining a receipt impracticable. Under such circumstances, the donor must maintain reliable written records regarding the contribution. The required content of such a record varies depending upon factors such as the type and value of property contributed.[396]

In addition to the foregoing recordkeeping requirements, substantiation requirements apply in the case of charitable contributions with a value of $250 or more. No charitable deduction is allowed for any contribution of $250 or more unless the taxpayer substantiates the contribution by a contemporaneous written acknowledgement of the contribution by the donee organization. Such acknowledgement must include the amount of cash and a description (but not value) of any property other than cash contributed, whether the donee provided any goods or services in consideration for the contribution, and a good faith estimate of the value of any such goods or services.[397] In general, if the total charitable deduction claimed for non-cash property is more than $500, the taxpayer must attach a completed Form 8283 (Noncash Charitable Contributions) to the taxpayer's return or the deduction is not allowed.[398] In general, taxpayers are required to obtain a qualified appraisal for donated property with a value of more than $5,000, and to attach an appraisal summary to the tax return.

Explanation of Provision

The provision more closely aligns the substantiation rules for money to the substantiation rules for property by providing that in the case of a charitable contribution of money, regardless of the amount, applicable recordkeeping requirements are satisfied only if the donor maintains as

[395] Treas. Reg. sec. 1.170A-13(a).

[396] Treas. Reg. sec. 1.170A-13(b).

[397] Sec. 170(f)(8).

[398] Sec. 170(f)(11).

a record of the contribution a bank record or a written communication from the donee showing the name of the donee organization, the date of the contribution, and the amount of the contribution. The recordkeeping requirements may not be satisfied by maintaining other written records. It is noted that currently, taxpayers are required to have a contemporaneous record of contributions of money, but that many taxpayers may not be aware of the requirement and do not keep a log of such contributions. The provision is intended to provide greater certainty, both to taxpayers and to the Secretary, in determining what may be deducted as a charitable contribution.

Effective Date

The provision is effective for contributions made in taxable years beginning after the date of enactment.

8. Contributions of fractional interests in tangible personal property (secs. 170, 2055, and 2522 of the Code)

Present Law

In general, a charitable deduction is not allowable for a contribution of a partial interest in property, such as an income interest, a remainder interest, or a right to use property.[399] A gift of an undivided portion of a donor's entire interest in property generally is not treated as a nondeductible gift of a partial interest in property.[400] For this purpose, an undivided portion of a donor's entire interest in property must consist of a fraction or percentage of each and every substantial interest or right owned by the donor in such property and must extend over the entire term of the donor's interest in such property.[401] A gift generally is treated as a gift of an undivided portion of a donor's entire interest in property if the donee is given the right, as a tenant in common with the donor, to possession, dominion, and control of the property for a portion of each year appropriate to its interest in such property.[402]

A charitable contribution deduction generally is not allowable for a contribution of a future interest in tangible personal property.[403] For this purpose, a future interest is one "in which a donor purports to give tangible personal property to a charitable organization, but has an understanding, arrangement, agreement, etc., whether written or oral, with the charitable organization which has the effect of reserving to, or retaining in, such donor a right to the use, possession, or enjoyment of the property."[404] Treasury regulations provide that section

[399] Secs. 170(f)(3)(A) (income tax), 2055(e)(2) (estate tax), and 2522(c)(2) (gift tax).

[400] Sec. 170(f)(3)(B)(ii).

[401] Treas. Reg. sec. 1.170A-7(b)(1).

[402] Treas. Reg. sec. 1.170A-7(b)(1).

[403] Sec. 170(a)(3).

[404] Treas. Reg. sec. 1.170A-5(a)(4).

170(a)(3), which generally denies a deduction for a contribution of a future interest in tangible personal property, "[has] no application in respect of a transfer of an undivided present interest in property. For example, a contribution of an undivided one-quarter interest in a painting with respect to which the donee is entitled to possession during three months of each year shall be treated as made upon the receipt by the donee of a formally executed and acknowledged deed of gift. However, the period of initial possession by the donee may not be deferred in time for more than one year."[405]

Explanation of Provision

In general, under present law and the provision a donor may take a deduction for a charitable contribution of a fractional interest in tangible personal property (such as an artwork), provided the donor satisfies the requirements for deductibility (including the requirements concerning contributions of partial interests and future interests in property), and in subsequent years make additional charitable contributions of interests in the same property.[406] Under the provision, the value of a donor's charitable deduction for the initial contribution of a fractional interest in an item of tangible personal property (or collection of such items) shall be determined as under current law (e.g., based upon the fair market value of the artwork at the time of the contribution of the fractional interest and considering whether the use of the artwork will be related to the donee's exempt purposes). For purposes of determining the deductible amount of each additional contribution of an interest (whether or not a fractional interest) in the same item of property, the fair market value of the item is the lesser of: (1) the value used for purposes of determining the charitable deduction for the initial fractional contribution; or (2) the fair market value of the item at the time of the subsequent contribution. This portion of the provision applies for income, gift, and estate tax purposes.

The provision provides for recapture of the income tax charitable deduction and gift tax charitable deduction under certain circumstances. First, if a donor makes an initial fractional contribution, then fails to contribute all of the donor's remaining interest in such property to the same donee before the earlier of 10 years from the initial fractional contribution or the donor's death, then the donee's charitable income and gift tax deductions for all previous contributions of interests in the item shall be recaptured (plus interest). If the donee of the initial contribution is no longer in existence as of such time, the donor's remaining interest may be contributed to another organization described in section 170(c) (which describes organizations to which contributions that are deductible for income tax purposes may be made). Second, if the donee of a fractional interest in an item of tangible personal property fails to take substantial physical possession of the item during the period described above (the possession requirement) or fails to use the property for an exempt use during the period described above (the related-use requirement), then the donee's charitable income and gift tax deductions for all previous contributions of interests in the item shall be recaptured (plus interest). If, for example, an art museum described in section 501(c)(3) that is the donee of a fractional interest in a painting

[405] Treas. Reg. sec. 1.170A-5(a)(2).

[406] See, e.g., *Winokur v. Commissioner*, 90 T.C. 733 (1988).

includes the painting in an art exhibit sponsored by the museum, such use generally will be treated as satisfying the related-use requirement of the provision.

In any case in which there is a recapture of a deduction as described in the preceding paragraph, the provision also imposes an additional tax in an amount equal to 10 percent of the amount recaptured.

Under the provision, no income or gift tax charitable deduction is allowed for a contribution of a fractional interest in an item of tangible personal property unless immediately before such contribution all interests in the item are owned (1) by the donor or (2) by the donor and the donee organization. The Secretary is authorized to make exceptions to this rule in cases where all persons who hold an interest in the item make proportional contributions of undivided interests in their respective shares of such item to the donee organization. For example, if A owns an undivided 40 percent interest in a painting and B owns an undivided 60 percent interest in the same painting, the Secretary may provide that A may take a deduction for a charitable contribution of less than the entire interest held by A, provided that both A and B make proportional contributions of undivided fractional interests in their respective shares of the painting to the same donee organization (e.g., if A contributes 50 percent of A's interest and B contributes 50 percent of B's interest).

It is intended that a contribution occurring before the date of enactment not be treated as an initial fractional contribution for purposes of the provision. Instead, the first fractional contribution by a taxpayer after the date of enactment would be considered the initial fractional contribution under the provision, regardless of whether the taxpayer had made a contribution of a fractional interest in the same item of tangible personal property prior to the date of enactment.

Effective Date

The provision is applicable for contributions, bequests, and gifts made after the date of enactment.

9. Proposals relating to appraisers and substantial and gross overstatement of valuations of property (secs. 170, 6662, 6664, 6696 and new sec. 6695A of the Code)

Present Law

Taxpayer penalties

Present law imposes accuracy-related penalties on a taxpayer in cases involving a substantial valuation misstatement or gross valuation misstatement relating to an underpayment of income tax.[407] For this purpose, a substantial valuation misstatement generally means a value claimed that is at least twice (200 percent or more) the amount determined to be the correct value, and a gross valuation misstatement generally means a value claimed that is at least four times (400 percent or more) the amount determined to be the correct value.

[407] Sec. 6662(b)(3) and (h).

The penalty is 20 percent of the underpayment of tax resulting from a substantial valuation misstatement and rises to 40 percent for a gross valuation misstatement. No penalty is imposed unless the portion of the underpayment attributable to the valuation misstatement exceeds $5,000 ($10,000 in the case of a corporation other than an S corporation or a personal holding company). Under present law, no penalty is imposed with respect to any portion of the understatement attributable to any item if (1) the treatment of the item on the return is or was supported by substantial authority, or (2) facts relevant to the tax treatment of the item were adequately disclosed on the return or on a statement attached to the return and there is a reasonable basis for the tax treatment. Special rules apply to tax shelters.

Present law also imposes an accuracy-related penalty on substantial or gross estate or gift tax valuation understatements.[408] In general, there is a substantial estate or gift tax understatement if the value of any property claimed on any return is 50 percent or less of the amount determined to be the correct amount, and a gross estate or gift tax understatement if such value is 25 percent or less of the amount determined to be the correct amount.

In addition, the accuracy-related penalties do not apply if a taxpayer shows there was reasonable cause for an underpayment and the taxpayer acted in good faith.[409]

Penalty for aiding and abetting understatement of tax

A penalty is imposed on a person who: (1) aids or assists in or advises with respect to a tax return or other document; (2) knows (or has reason to believe) that such document will be used in connection with a material tax matter; and (3) knows that this would result in an understatement of tax of another person. In general, the amount of the penalty is $1,000. If the document relates to the tax return of a corporation, the amount of the penalty is $10,000.

Qualified appraisals

Present law requires a taxpayer to obtain a qualified appraisal for donated property with a value of more than $5,000, and to attach an appraisal summary to the tax return.[410] Treasury Regulations state that a qualified appraisal means an appraisal document that, among other things: (1) relates to an appraisal that is made not earlier than 60 days prior to the date of contribution of the appraised property and not later than the due date (including extensions) of the return on which a deduction is first claimed under section 170; (2) is prepared, signed, and dated by a qualified appraiser; (3) includes (a) a description of the property appraised; (b) the fair market value of such property on the date of contribution and the specific basis for the valuation; (c) a statement that such appraisal was prepared for income tax purposes; (d) the qualifications of

[408] Sec. 6662(g) and (h).

[409] Sec. 6664(c).

[410] Sec. 170(f)(11).

the qualified appraiser; and (e) the signature and taxpayer identification number of such appraiser; and (4) does not involve an appraisal fee that violates certain prescribed rules.[411]

Qualified appraisers

Treasury Regulations define a qualified appraiser as a person who holds himself or herself out to the public as an appraiser or performs appraisals on a regular basis, is qualified to make appraisals of the type of property being valued (as determined by the appraiser's background, experience, education and membership, if any, in professional appraisal associations), is independent, and understands that an intentionally false or fraudulent overstatement of the value of the appraised property may subject the appraiser to civil penalties.[412]

Appraiser oversight

The Secretary is authorized to regulate the practice of representatives of persons before the Department of the Treasury ("Department").[413] After notice and hearing, the Secretary is authorized to suspend or disbar from practice before the Department or the Internal Revenue Service ("IRS") a representative who is incompetent, who is disreputable, who violates the rules regulating practice before the Department or the IRS, or who (with intent to defraud) willfully and knowingly misleads or threatens the person being represented (or a person who may be represented).

The Secretary also is authorized to bar from appearing before the Department or the IRS, for the purpose of offering opinion evidence on the value of property or other assets, any individual against whom a civil penalty for aiding and abetting the understatement of tax has been assessed. Thus, an appraiser who aids or assists in the preparation or presentation of an appraisal will be subject to disciplinary action if the appraiser knows that the appraisal will be used in connection with the tax laws and will result in an understatement of the tax liability of another person. The Secretary has authority to provide that the appraisals of an appraiser who has been disciplined have no probative effect in any administrative proceeding before the Department or the IRS.

Explanation of Provision

Taxpayer penalties

The provision lowers the thresholds for imposing accuracy-related penalties on a taxpayer. Under the provision, a substantial valuation misstatement exists when the claimed value of any property is 150 percent or more of the amount determined to be the correct value. A

---

[411] Treas. Reg. sec. 1.170A-13(c)(3).

[412] Treas. Reg. sec. 1.170A-13(c)(5)(i).

[413] 31 U.S.C. sec. 330.

gross valuation misstatement occurs when the claimed value of any property is 200 percent or more of the amount determined to be the correct value.

The provision tightens the thresholds for imposing accuracy-related penalties with respect to the estate or gift tax. Under the provision, a substantial estate or gift tax valuation misstatement exists when the claimed value of any property is 65 percent or less of the amount determined to be the correct value. A gross estate or gift tax valuation misstatement exists when the claimed value of any property is 40 percent or less of the amount determined to be the correct value.

Under the provision, the reasonable cause exception to the accuracy-related penalty does not apply in the case of gross valuation misstatements.

Appraiser oversight

Appraiser penalties

The provision establishes a civil penalty on any person who prepares an appraisal that is to be used to support a tax position if such appraisal results in a substantial or gross valuation misstatement. The penalty is equal to the greater of $1,000 or 10 percent of the understatement of tax resulting from a substantial or gross valuation misstatement, up to a maximum of 125 percent of the gross income derived from the appraisal. Under the provision, the penalty does not apply if the appraiser establishes that it was "more likely than not" that the appraisal was correct.

Disciplinary proceeding

The provision eliminates the requirement that the Secretary assess against an appraiser the civil penalty for aiding and abetting the understatement of tax before such appraiser may be subject to disciplinary action. Thus, the Secretary is authorized to discipline appraisers after notice and hearing. Disciplinary action may include, but is not limited to, suspending or barring an appraiser from: preparing or presenting appraisals on the value of property or other assets to the Department or the IRS; appearing before the Department or the IRS for the purpose of offering opinion evidence on the value of property or other assets; and providing that the appraisals of an appraiser who has been disciplined have no probative effect in any administrative proceeding before the Department or the IRS.

Qualified appraisers

The provision defines a qualified appraiser as an individual who (1) has earned an appraisal designation from a recognized professional appraiser organization or has otherwise met minimum education and experience requirements to be determined by the IRS in regulations; (2) regularly performs appraisals for which he or she receives compensation; (3) can demonstrate verifiable education and experience in valuing the type of property for which the appraisal is being performed; (4) has not been prohibited from practicing before the IRS by the Secretary at any time during the three years preceding the conduct of the appraisal; and (5) is not excluded from being a qualified appraiser under applicable Treasury regulations.

Qualified appraisals

The provision defines a qualified appraisal as an appraisal of property prepared by a qualified appraiser (as defined by the provision) in accordance with generally accepted appraisal standards and any regulations or other guidance prescribed by the Secretary.

Effective Date

The provision amending the accuracy-related penalty applies to returns filed after the date of enactment. The provision establishing a civil penalty that may be imposed on any person who prepares an appraisal that is to be used to support a tax position if such appraisal results in a substantial or gross valuation misstatement applies to appraisals prepared with respect to returns or submissions filed after the date of enactment. The provisions relating to appraiser oversight apply to appraisals prepared with respect to returns or submissions filed after the date of enactment. With respect to any contribution of a qualified real property interest which is a restriction with respect to the exterior of a building described in section 170(h)(4)(C)(ii) (currently designated section 170(h)(4)(B)(ii), relating to certain property located in a registered historic district and certified as being of historic significance to the district), and any appraisal with respect to such contribution, the provision generally applies to returns filed after July 25, 2006.

10. Establish additional exemption standards for credit counseling organizations (secs. 501 and 513 of the Code)

Present Law

Under present law, a credit counseling organization may be exempt as a charitable or educational organization described in section 501(c)(3), or as a social welfare organization described in section 501(c)(4). The IRS has issued two revenue rulings holding that certain credit counseling organizations are exempt as charitable or educational organizations or as social welfare organizations.

In Revenue Ruling 65-299,[414] an organization whose purpose was to assist families and individuals with financial problems, and help reduce the incidence of personal bankruptcy, was determined to be a social welfare organization described in section 501(c)(4). The organization counseled people in financial difficulties, advised applicants on payment of debts, and negotiated with creditors and set up debt repayment plans. The organization did not restrict its services to the poor, made no charge for counseling services, and made a nominal charge for certain services to cover postage and supplies. For financial support, the organization relied on voluntary contributions from local businesses, lending agencies, and labor unions.

[414] Rev. Rul. 65-299, 1965-2 C.B. 165.

In Revenue Ruling 69-441,[415] the IRS ruled an organization was a charitable or educational organization exempt under section 501(c)(3) by virtue of aiding low-income people who had financial problems and providing education to the public. The organization in that ruling had two functions: (1) educating the public on personal money management, such as budgeting, buying practices, and the sound use of consumer credit through the use of films, speakers, and publications; and (2) providing individual counseling to low-income individuals and families without charge. As part of its counseling activities, the organization established debt management plans for clients who required such services, at no charge to the clients.[416] The organization was supported by contributions primarily from creditors, and its board of directors was comprised of representatives from religious organizations, civic groups, labor unions, business groups, and educational institutions.

In 1976, the IRS denied exempt status to an organization, Consumer Credit Counseling Service of Alabama, whose activities were distinguishable from those in Revenue Ruling 69-441 in that (1) it did not restrict its services to the poor, and (2) it charged a nominal fee for its debt management plans.[417] The organization provided free information to the general public through the use of speakers, films, and publications on the subjects of budgeting, buying practices, and the use of consumer credit. It also provided counseling to debt-distressed individuals, not necessarily poor or low-income, and provided debt management plans at the cost of $10 per month, which was waived in cases of financial hardship. Its debt management activities were a relatively small part of its overall activities. The district court determined the organization qualified as charitable and educational within section 501(c)(3), finding the debt management plans to be an integral part of the agency's counseling function, and that its debt management activities were incidental to its principal functions, as only approximately 12 percent of the counselors' time was applied to such programs and the charge for the service was nominal. The court also considered the facts that the agency was publicly supported, and that it had a board dominated by members of the general public, as factors indicating a charitable operation.[418]

A recent estimate shows the number of credit counseling organizations increased from approximately 200 in 1990 to over 1,000 in 2002.[419] During the period from 1994 to late 2003,

---

[415] Rev. Rul. 69-441, 1969-2 C.B. 115.

[416] Debt management plans are debt payment arrangements, including debt consolidation arrangements, entered into by a debtor and one or more of the debtor's creditors, generally structured to reduce the amount of a debtor's regular ongoing payment by modifying the interest rate, minimum payment, maturity or other terms of the debt. Such plans frequently are promoted as a means for a debtor to restructure debt without filing for bankruptcy.

[417] *Consumer Credit Counseling Service of Alabama, Inc. v. U.S.*, 44 A.F.T.R. 2d (RIA) 5122 (D.D.C. 1978). The case involved 24 agencies throughout the United States.

[418] *See also, Credit Counseling Centers of Oklahoma, Inc., v. U.S.*, 45 A.F.T.R. 2d (RIA) 1401 (D.D.C. 1979) (holding the same on virtually identical facts).

[419] Opening Statement of The Honorable Max Sandlin, Hearing on Non-Profit Credit Counseling Organizations, House Ways and Means Committee, Subcommittee on Oversight (November 20, 2003).

1,215 credit counseling organizations applied to the IRS for tax exempt status under section 501(c)(3), including 810 during 2000 to 2003.[420] The IRS has recognized more than 850 credit counseling organizations as tax exempt under section 501c)((3).[421] Few credit counseling organizations have sought section 501(c)(4) status, and the IRS reports it has not seen any significant increase in the number or activity of such organizations operating as social welfare organizations.[422] As of late 2003, there were 872 active tax-exempt credit counseling agencies operating in the United States.[423]

A credit counseling organization described in section 501(c)(3) is exempt from certain Federal and State consumer protection laws that provide exemptions for organizations described therein.[424] Some believe that these exclusions from Federal and State regulation may be a primary motivation for the recent increase in the number of organizations seeking and obtaining exempt status under section 501(c)(3).[425] Such regulatory exemptions generally are not available for social welfare organizations described in section 501(c)(4).

[424] *E.g.*, The Credit Repair Organizations Act, 15 U.S.C. section 1679 *et seq*., effective April 1, 1997 (imposing restrictions on credit repair organizations that are enforced by the Federal Trade Commission, including forbidding the making of untrue or misleading statements and forbidding advance payments; section 501(c)(3) organizations are explicitly exempt from such regulation). Testimony of Commissioner Mark Everson before the House Ways and Means Committee, Subcommittee on Oversight (November 20, 2003) (California's consumer protections laws that impose strict standards on credit service organizations and the credit repair industry do not apply to nonprofit organizations that have received a final determination from the IRS that they are exempt from tax under section 501(c)(3) and are not private foundations).

[425] Testimony of Commissioner Mark Everson before the House Ways and Means Committee, Subcommittee on Oversight (November 20, 2003).

Congress recently conducted hearings investigating the activities of credit counseling organizations under various consumer protection laws,[426] such as the Federal Trade Commission Act.[427] In addition, the IRS commenced a broad examination and compliance program with respect to the credit counseling industry. On May 15, 2006, the IRS announced that over the past two years, it had been auditing 63 credit counseling agencies, representing more than 40 percent of the revenue in the industry. Audits of 41 organizations, representing more than 40 percent of the revenue in the industry have been completed as of that date. All of such completed audits resulted in revocation, proposed revocation, or other termination of tax-exempt status.[428] In addition, the IRS released two legal documents that provide a legal framework for determining the exempt status and related issues with respect to credit counseling organizations.[429] In CCA 200620001, the IRS found that "[t]he critical inquiry is whether a credit counseling organization conducts its counseling program to improve an individual debtor's understanding of his financial problems and improve his ability to address those problems." The CCA concluded that whether a credit counseling organization primarily furthers educational purposes

> can be determined by assessing the methodology by which the organization conducts its counseling activities. The process an organization uses to interview clients and develop recommendations, train its counselors and market its services can distinguish between an organization whose object is to improve a person's knowledge and skills to manage his personal debt, and an organization that is offering counseling primarily as a mechanism to enroll individuals in a specific option (e.g., debt management plans) without considering the individual's best interest.

Under the Bankruptcy Abuse Prevention and Consumer Protection Act of 2005, Public Law 109-8, an individual generally may not be a debtor in bankruptcy unless such individual has, within 180 days of filing a petition for bankruptcy, received from an approved nonprofit budget and credit counseling agency an individual or group briefing that outlines the opportunities for available credit counseling and assists the individual in performing a related

budget analysis.[430] The clerk of the court must maintain a publicly available list of nonprofit budget and credit counseling agencies approved by the U.S. Trustee (or bankruptcy administrator). In general, the U.S. Trustee (or bankruptcy administrator) shall only approve an agency that demonstrates that it will provide qualified counselors, maintain adequate provision for safekeeping and payment of client funds, provide adequate counseling with respect to client credit problems, and deal responsibly and effectively with other matters relating to the quality, effectiveness, and financial security of the services it provides. The minimum qualifications for approval of such an agency include: (1) in general, having an independent board of directors; (2) charging no more than a reasonable fee, and providing services without regard to ability to pay; (3) adequate provision for safekeeping and payment of client funds; (4) provision of full disclosures to clients; (5) provision of adequate counseling with respect to a client's credit problems; (6) trained counselors who receive no commissions or bonuses based on the outcome of the counseling services; (7) experience and background in providing credit counseling; and (8) adequate financial resources to provide continuing support services for budgeting plans over the life of any repayment plan. An individual debtor must file with the court a certificate from the approved nonprofit budget and credit counseling agency that provided the required services describing the services provided, and a copy of the debt management plan, if any, developed through the agency.[431]

Explanation of Provision

Requirements for exempt status of credit counseling organizations

The provision establishes standards that a credit counseling organization must satisfy, in addition to present law requirements, in order to be organized and operated either as an organization described in section 501(c)(3) or in section 501(c)(4). The provision does not diminish the requirements set forth recently by the IRS in Chief Counsel Advice 200431023 or Chief Counsel Advice 200620001 but builds on and is consistent with such requirements, and the analysis therein. The provision is not intended to raise any question about IRS actions taken, and the IRS is expected to continue its vigorous examination of the credit counseling industry, applying the additional standards provided by the provision. The provision does not and is not intended to affect the approval process for credit counseling agencies under Public Law 109-8. Public Law 109-8 requires that an approved credit counseling agency be a nonprofit, and does not require that an approved agency be a section 501(c)(3) organization. It is expected that the

[430] This requirement does not apply in certain circumstances, such as: (1) in general, where a debtor resides in a district for which the U.S. Trustee has determined that the approved counseling agencies for such district are not reasonably able to provide adequate services to additional individuals; (2) where exigent circumstances merit a waiver, the individual seeking bankruptcy protection files an appropriate certification with the court, and the certification is acceptable to the court; and (3) in general, where a court determines, after notice and hearing, that the individual is unable to complete the requirement because of incapacity, disability, or active military duty in a military combat zone.

[431] The Act also requires that, prior to discharge of indebtedness under chapter 7 or chapter 13, a debtor complete an approved instructional course concerning personal financial management, which course need not be conducted by a nonprofit agency.

Department of Justice shall continue to approve agencies for purposes of providing pre-bankruptcy counseling based on criteria that are consistent with such Public Law.

Under the provision, an organization that provides credit counseling services as a substantial purpose of the organization ("credit counseling organization") is eligible for exemption from Federal income tax only as a charitable or educational organization under section 501(c)(3) or as a social welfare organization under section 501(c)(4), and only if (in addition to present-law requirements) the credit counseling organization is organized and operated in accordance with the following:

1. The organization provides credit counseling services tailored to the specific needs and circumstances of the consumer;

2. The organization makes no loans to debtors (other than loans with no fees or interest) and does not negotiate the making of loans on behalf of debtors;[432]

3. The organization provides services for the purpose of improving a consumer's credit record, credit history, or credit rating only to the extent that such services are incidental to providing credit counseling services and does not charge any separately stated fee for any such services;[433]

4. The organization does not refuse to provide credit counseling services to a consumer due to inability of the consumer to pay, the ineligibility of the consumer for debt management plan enrollment, or the unwillingness of a consumer to enroll in a debt management plan;

5. The organization establishes and implements a fee policy to require that any fees charged to a consumer for its services are reasonable,[434] allows for the waiver of fees if the consumer is unable to pay, and except to the extent allowed by State law prohibits charging any fee based in whole or in part on a percentage of the consumer's debt, the consumer's payments to be made pursuant to a debt management plan, or on the projected or actual savings to the consumer resulting from enrolling in a debt management plan;

---

[432] In general, negotiation of a loan involves negotiation of the terms of a loan, rather than the processing of a loan. Organizations that provide assistance to consumers to obtain a loan from the Department of Housing and Urban Development, for example, are not necessarily negotiating a loan for a consumer.

[433] Accordingly, a credit counseling organization may provide credit repair type services, but only to the extent that the provision of such services is a direct outgrowth of the provision of credit counseling services.

[434] Whether a credit counseling organization's fees are consistent with specific State law requirements is evidence of the reasonableness of fees but is not determinative.

6. The organization at all times has a board of directors or other governing body (a) that is controlled by persons who represent the broad interests of the public, such as public officials acting in their capacities as such, persons having special knowledge or expertise in credit or financial education, and community leaders; (b) not more than 20 percent of the voting power of which is vested in persons who are employed by the organization or who will benefit financially, directly or indirectly, from the organization's activities (other than through the receipt of reasonable directors' fees or the repayment of consumer debt to creditors other than the credit counseling organization or its affiliates) and (c) not more than 49 percent of the voting power of which is vested in persons who are employed by the organization or who will benefit financially, directly or indirectly, from the organization's activities (other than through the receipt of reasonable directors' fees);[435]

7. The organization does not own (except with respect to a section 501(c)(3) organization) more than 35 percent of the total combined voting power of a corporation (or profits or beneficial interest in the case of a partnership or trust or estate) that is in the trade or business of lending money, repairing credit, or providing debt management plan services, payment processing, and similar services; and

8. The organization receives no amount for providing referrals to others for debt management plan services, and pays no amount to others for obtaining referrals of consumers.[436]

Additional requirements for charitable and educational organizations

Under the provision, a credit counseling organization is described in section 501(c)(3) only if, in addition to satisfying the above requirements and the requirements of section 501(c)(3), the organization is organized and operated such that the organization (1) does not solicit contributions from consumers during the initial counseling process or while the consumer is receiving services from the organization and (2) the aggregate revenues of the organization that are from payments of creditors of consumers of the organization and that are attributable to debt management plan services do not exceed the applicable percentage of the total revenues of the organization. For credit counseling organizations in existence on the date of enactment, the

[435] The requirements described in paragraphs 4, 5, and 6 above address core issues that are related to tax-exempt status and that have proved to be problematic in the credit counseling industry--the provision of services and waiver of fees without regard to ability to pay, the establishment of a reasonable fee policy, and the presence of independent board members. No inference is intended through the provision of these specific requirements on credit counseling organizations that similar or more stringent requirements should not be adhered to by other exempt organizations providing fees for services. Rather, the provision affirms the importance of these core issues to the matter of tax exemption, both to credit counseling organizations and to other types of exempt organizations.

[436] If a credit counseling organization pays or receives a fee, for example, for using or maintaining a locator service for consumers to find a credit counseling organization, such a fee is not considered a referral.

applicable percentage is 80 percent for the first taxable year of the organization beginning after the date which is one year after the date of enactment, 70 percent for the second such taxable year beginning after such date, 60 percent for the third such taxable year beginning after such date, and 50 percent thereafter. For new credit counseling organizations, the applicable percentage is 50 percent for taxable years beginning after the date of enactment. Satisfaction of the aggregate revenues requirement is not a safe harbor; all other requirements of the provision (and of section 501(c)(3)) pertaining to section 501(c)(3) organizations also must be satisfied. Satisfaction of the aggregate revenues requirement means only that an organization has not automatically failed to be organized or operated consistent with exempt purposes. Compliance with the revenues test does not mean that the organization's debt management plan services activity is at a level that organizationally or operationally is consistent with exempt status. In other words, satisfaction of the aggregate revenues requirement (as a preliminary matter in an exemption application, or on an ongoing operational basis) provides no affirmative evidence that an organization's primary purpose is an exempt purpose, or that the revenues that are subject to the limitation (or debt management plan services revenues more generally) are related to exempt purposes. As described below, whether revenues from such activity are substantially related to exempt purposes depends on the facts and circumstances, that is, satisfaction of the aggregate revenues requirement generally is not relevant for purposes of whether any of an organization's revenues are revenues from an unrelated trade or business. Failure to satisfy the aggregate revenues requirement does not disqualify the organization from recognition of exemption under section 501(c)(4).

Additional requirement for social welfare organizations

Under the provision, a credit counseling organization is described in section 501(c)(4) only if, in addition to satisfying the above requirements applicable to such organizations, the organization notifies the Secretary, in such manner as the Secretary may by regulations prescribe, that it is applying for recognition as a credit counseling organization.

Debt management plan services treated as an unrelated trade or business

Under the provision, debt management plan services are treated as an unrelated trade or business for purposes of the tax on income from an unrelated trade or business to the extent such services are provided by an organization that is not a credit counseling organization. With respect to the provision of debt management plan services by a credit counseling organization, in order for the income from such services not to be unrelated business income, it is intended that, consistent with current law, the debt management plan service with respect to such income (1) must contribute importantly to the accomplishment of credit counseling services, and (2) must not be conducted on a larger scale than reasonably is necessary for the accomplishment of such services. For example, the provision of debt management plan services would not be substantially related to accomplishing exempt purposes if the organization recommended and enrolled an individual in a debt management plan only after determining whether the individual satisfied the financial criteria established by the creditors for such plan, without (1) considering whether it was an appropriate action in light of the individual's particular needs and objectives, (2) discussing the disadvantages of a debt management plan with the consumer, and (3) presenting other possible options to such consumer.

Definitions

Credit counseling services

Credit counseling services are (a) the provision of educational information to the general public on budgeting, personal finance, financial literacy, saving and spending practices, and the sound use of consumer credit; (b) the assisting of individuals and families with financial problems by providing them with counseling; or (c) any combination of such activities.

Debt management plan services

Debt management plan services are services related to the repayment, consolidation, or restructuring of a consumer's debt, and includes the negotiation with creditors of lower interest rates, the waiver or reduction of fees, and the marketing and processing of debt management plans.

Effective Date

In general, the provision applies to taxable years beginning after the date of enactment. For a credit counseling organization that is described in section 501(c)(3) or 501(c)(4) on the date of enactment, the provision is effective for taxable years beginning after the date that is one year after the date of enactment.

11. Expand the base of the tax on private foundation net investment income (sec. 4940 of the Code)

Present Law

In general

Under section 4940(a) of the Code, private foundations that are recognized as exempt from Federal income tax under section 501(a) of the Code are subject to a two-percent excise tax on their net investment income. Private foundations that are not exempt from tax, such as certain charitable trusts,[437] also are subject to an excise tax under section 4940(b) based on net investment income and unrelated business income. The two-percent rate of tax is reduced to one-percent if certain requirements are met in a taxable year.[438] Unlike certain other excise taxes imposed on private foundations, the tax based on investment income does not result from a violation of substantive law by the private foundation; it is solely an excise tax.

The tax on taxable private foundations under section 4940(b) is equal to the excess of the sum of the excise tax that would have been imposed under section 4940(a) if the foundation were tax exempt and the amount of the unrelated business income tax that would have been imposed if

[437] *See* sec. 4947(a)(1).

[438] Sec. 4940(e).

the foundation were tax exempt, over the income tax imposed on the foundation under subtitle A of the Code.

Net investment income

Internal Revenue Code

In general, net investment income is defined as the amount by which the sum of gross investment income and capital gain net income exceeds the deductions relating to the production of gross investment income.[439]

Gross investment income is the gross amount of income from interest, dividends, rents, payments with respect to securities loans, and royalties. Gross investment income does not include any income that is included in computing a foundation's unrelated business taxable income.[440]

Capital gain net income takes into account only gains and losses from the sale or other disposition of property used for the production of interest, dividends, rents, and royalties, and property used for the production of income included in computing the unrelated business income tax (except to the extent the gain or loss is taken into account for purposes of such tax). Losses from sales or other dispositions of property are allowed only to the extent of gains from such sales or other dispositions, and no capital loss carryovers are allowed.[441]

Treasury Regulations and case law

The Treasury regulations elaborate on the Code definition of net investment income. The regulations cite items of investment income listed in the Code, and in addition clarify that net investment income includes interest, dividends, rents, and royalties derived from all sources, including from assets devoted to charitable activities. For example, interest received on a student loan is includible in the gross investment income of a foundation making the loan.[442]

The regulations further provide that gross investment income includes certain items of investment income that are described in the unrelated business income tax regulations.[443] Such additional items include payments with respect to securities loans (an item added to the Code in

[439] Sec. 4940(c)(1). Net investment income also is determined by applying section 103 (generally providing an exclusion for interest on certain State and local bonds) and section 265 (generally disallowing the deduction for interest and certain other expenses with respect to tax-exempt income). Sec. 4940(c)(5).

[440] Sec. 4940(c)(2).

[441] Sec. 4940(c)(4).

[442] Treas. Reg. sec. 53.4940-1(d)(1).

[443] *Id.*

1978), annuities, income from notional principal contracts, and other substantially similar income from ordinary and routine investments to the extent determined by the Commissioner.[444] These latter three categories of income are not enumerated as net investment income in the Code.

The Treasury regulations also elaborate on the Code definition of capital gain net income. The regulations provide that the only capital gains and losses that are taken into account are (1) gains and losses from the sale or other disposition of property held by a private foundation for investment purposes (other than program related investments), and (2) property used for the production of income included in computing the unrelated business income tax (except to the extent the gain or loss is taken into account for purposes of such tax).

This definition of capital gain net income builds on the definition provided in the Code by providing an exception for gain and loss from program related investments and by stating, in addition, that "gains and losses from the sale or other disposition of property used for the exempt purposes of the private foundation are excluded."[445] As an example, the regulations provide that gain or loss on the sale of buildings used for the foundation's exempt activities are not taken into account for purposes of the section 4940 tax. If a foundation uses exempt income for exempt purposes and (other than incidentally) for investment purposes, then the portion of the gain or loss received upon sale or other disposition that is allocable to the investment use is taken into account for purposes of the tax.

The regulations further provide that "property shall be treated as held for investment purposes even though such property is disposed of by the foundation immediately upon its receipt, if it is property of a type which generally produces interest, dividends, rents, royalties, or capital gains through appreciation (for example, rental real estate, stock, bonds, mineral interest, mortgages, and securities)."[446]

This regulation has been challenged in the courts. The regulation says that property is treated as held for investment purposes if it is of a type that "generally produces" certain types of income. By contrast, the Code provides that the property be "used" to produce such income. In Zemurray Foundation v. United States, 687 F.2d 97 (5th Cir. 1982), the taxpayer foundation challenged the Treasury's attempt to tax under section 4940 capital gain on the sale of timber property. The taxpayer asserted that the property was not actually used to produce investment income, and that the Treasury Regulation was invalid because the regulation would subject to tax property that is of a type that could generally be used to produce investment income. On this issue, the court upheld the Treasury regulation, reasoning that the regulation's use of the phrase "generally used," though permitting taxation "so long as the property sold is usable to produce the applicable types of income, regardless of whether the property is actually used to produce income or not" was not unreasonable or plainly inconsistent with the statute.[447] However, on

[444] Treas. Reg. sec. 1.512(b)-1(a)(1).

[445] Treas. Reg. sec. 53.4940-1(f)(1).

[446] *Id.*

[447] *Zemurray Foundation v. United States*, 687 F.2d 97, 100 (5th Cir. 1982).

remand to the district court, the district court concluded that the timber property at issue, though a type of property generally used to produce investment income, was not susceptible for such use.[448] Thus, the district court concluded that the Treasury could not tax the gain under this portion of the regulation.

The question then turned to the taxpayer's second challenge to the regulation. At issue was the meaning of the regulatory phrase "capital gains through appreciation." The regulation provides that if property is of a type that generally produces capital gains through appreciation, then the gain is subject to tax. The Treasury argued that the timber property at issue, although held by the court not to be property (in this case) susceptible for use to produce interest, dividends, rents, or royalties, still was held by the taxpayer to produce capital gain through appreciation and therefore the gain should be subject to tax under the regulation.

On this issue, the court held for the taxpayer, reasoning that the language of the Code clearly is limited to certain gains and losses, e.g., the court cited the Code language providing that "there shall be taken into account only gains and losses from the sale or other disposition of property used for the production of interest, dividends, rents, and royalties . . . ."[449] The court noted that "capital gains through appreciation" is not enumerated in the statute. The court used as an example a jade figurine held by a foundation. Jade figurines do not generally produce interest, dividends, rents, or royalties, but gain on the sale of such a figurine would be taxable under the "capital gains through appreciation" standard, yet such standard does not appear in the statute. After Zemurray, the Treasury generally conceded this issue.[450]

With respect to capital losses, the Code provides that carryovers are not permitted, whereas the regulations state that neither carryovers nor carrybacks are permitted.[451]

Application of Zemurray to the Code and the regulations

Applying the Zemurray case to the Code and regulations results in a general principle for purposes of present law: private foundations are subject to tax under section 4940 only on the items of income and only on gains and losses specifically enumerated therein. Under this principle, private foundations generally are not subject to the section 4940 tax on other substantially similar types of income from ordinary and routine investments, notwithstanding Treasury regulations to the contrary. In addition, the regulations provide that gain or loss from the sale or other disposition of assets used for exempt purposes, with specific reference to program-related investments, is excluded. The Code provides for no such blanket exclusion; thus, under the language of the Code and the reasoning of Zemurray, if a foundation provided

---

[448] *Zemurray Foundation v. United States*, 53 A.F.T.R. 2d (RIA) 842 (E. D. La. 1983).

[449] *Zemurray Foundation v. United States*, 755 F.2d 404 (5th Cir. 1985), 413 (citing Code sec. 4940(c)(4)(A).

[450] G.C.M. 39538 (July 23, 1986).

[451] Treas. Reg. sec. 53.4940-1(f)(3).

office space at below market rent to a charitable organization for use in the organization's exempt purposes, gain on the sale of the building by the foundation should be subject to the section 4940 tax despite the Treasury regulations.[452]

In addition, under the logic of Zemurray, capital loss carrybacks arguably are permitted, notwithstanding Treasury regulations to the contrary, because the Code mentions only a bar on use of carryovers and says nothing about carrybacks.

Explanation of Provision

The provision amends the definition of gross investment income (including for purposes of capital gain net income) to include items of income that are similar to the items presently enumerated in the Code. Such similar items include income from notional principal contracts, annuities, and other substantially similar income from ordinary and routine investments, and, with respect to capital gain net income, capital gains from appreciation, including capital gains and losses from the sale or other disposition of assets used to further an exempt purpose.

Certain gains and losses are not taken into account in determining capital gain net income. Specifically, under the provision, no gain or loss shall be taken into account with respect to any portion of property used for a period of not less than one year for a purpose or function constituting the basis of the private foundation's exemption, if the entire property is exchanged immediately following such period solely for property of like kind which is to be used primarily for a purpose or function constituting the basis for such foundation's exemption. Rules similar to the rules of section 1031 (relating to exchange of property held for productive use or investment) apply, including, but not limited to, the exceptions of section 1031(a)(2) and the rule of section 1031(a)(3) regarding completion of the exchange within 180 days.

The provision provides that there are no carrybacks of losses from sales or other dispositions of property.

Effective Date

The provision is effective for taxable years beginning after the date of enactment.

12. Definition of convention or association of churches (sec. 7701 of the Code)

Present Law

Under present law, an organization that qualifies as a "convention or association of churches" (within the meaning of sec. 170(b)(1)(A)(i)) is not required to file an annual return,[453] is subject to the church tax inquiry and church tax examination provisions applicable to

[452] *See also* the example in Treas. Reg. sec. 53.4940-1(f)(1).

[453] Sec. 6033(a)(2)(A)(i).

organizations claiming to be a church,[454] and is subject to certain other provisions generally applicable to churches.[455] The Internal Revenue Code does not define the term "convention or association of churches."

Explanation of Provision

The provision provides that an organization that otherwise is a convention or association of churches does not fail to so qualify merely because the membership of the organization includes individuals as well as churches, or because individuals have voting rights in the organization.

Effective Date

The provision is effective on the date of enactment.

13. Notification requirement for exempt entities not currently required to file an annual information return (secs. 6033, 6652, and 7428 of the Code)

Present Law

Under present law, the requirement that an exempt organization file an annual information return does not apply to several categories of exempt organizations. Organizations excepted from the filing requirement include organizations (other than private foundations), the gross receipts of which in each taxable year normally are not more than $25,000.[456] Also exempt from the requirement are churches, their integrated auxiliaries, and conventions or associations of churches; the exclusively religious activities of any religious order; section 501(c)(1)

---

[454] Sec. 7611(h)(1)(B).

[455] *See, e.g.*, Sec. 402(g)(8)(B) (limitation on elective deferrals); sec. 403(b)(9)(B) (definition of retirement income account); sec. 410(d) (election to have participation, vesting, funding, and certain other provisions apply to church plans); sec. 414(e) (definition of church plan); sec. 415(c)(7) (certain contributions by church plans); sec. 501(h)(5) (disqualification of certain organizations from making the sec. 501(h) election regarding lobbying expenditure limits); sec. 501(m)(3) (definition of commercial-type insurance); sec. 508(c)(1)(A) (exception from requirement to file application seeking recognition of exempt status); sec. 512(b)(12) (allowance of up to $1,000 deduction for purposes of determining unrelated business taxable income); sec. 514(b)(3)(E) (definition of debt-financed property); sec. 3121(w)(3)(A) (election regarding exemption from social security taxes); sec. 3309(b)(1) (application of federal unemployment tax provisions to services performed in the employ of certain organizations); sec. 6043(b)(1) (requirement to file a return upon liquidation or dissolution of the organization); and sec. 7702(j)(3)(A) (treatment of certain death benefit plans as life insurance).

[456] Sec. 6033(a)(2); Treas. Reg. sec. 1.6033-2(a)(2)(i); Treas. Reg. sec. 1.6033-2(g)(1). Sec. 6033(a)(2)(A)(ii) provides a $5,000 annual gross receipts exception from the annual reporting requirements for certain exempt organizations. In Announcement 82-88, 1982-25 I.R.B. 23, the IRS exercised its discretionary authority under section 6033 to increase the gross receipts exception to $25,000, and enlarge the category of exempt organizations that are not required to file Form 990.

instrumentalities of the United States; section 501(c)(21) trusts; an interchurch organization of local units of a church; certain mission societies; certain church-affiliated elementary and high schools; certain State institutions whose income is excluded from gross income under section 115; certain governmental units and affiliates of governmental units; and other organizations that the IRS has relieved from the filing requirement pursuant to its statutory discretionary authority.

Explanation of Provision

The provision requires organizations that are excused from filing an information return by reason of normally having gross receipts below a certain specified amount (generally, under $25,000) to furnish to the Secretary annually, in electronic form, the legal name of the organization, any name under which the organization operates or does business, the organization's mailing address and Internet web site address (if any), the organization's taxpayer identification number, the name and address of a principal officer, and evidence of the organization's continuing basis for its exemption from the generally applicable information return filing requirements. Upon such organization's termination of existence, the organization is required to furnish notice of such termination.

The provision provides that if an organization fails to provide the required notice for three consecutive years, the organization's tax-exempt status is revoked. In addition, if an organization that is required to file an annual information return under section 6033(a) (Form 990) fails to file such an information return for three consecutive years, the organization's tax-exempt status is revoked. If an organization fails to meet its filing obligation to the IRS for three consecutive years in cases where the organization is subject to the information return filing requirement in one or more years during a three-year period and also is subject to the notice requirement for one or more years during the same three-year period, the organization's tax-exempt status is revoked.

A revocation under the provision is effective from the date that the Secretary determines was the last day the organization could have timely filed the third required information return or notice. To again be recognized as tax-exempt, the organization must apply to the Secretary for recognition of tax-exemption, irrespective of whether the organization was required to make an application for recognition of tax-exemption in order to gain tax-exemption originally.

If, upon application for tax-exempt status after a revocation under the provision, the organization shows to the satisfaction of the Secretary reasonable cause for failing to file the required annual notices or returns, the organization's tax-exempt status may, in the discretion of the Secretary, be reinstated retroactive to the date of revocation. An organization may not challenge under the Code's declaratory judgment procedures (section 7428) a revocation of tax-exemption made pursuant to the provision.

There is no monetary penalty for failure to file the notice under the provision. Like other information returns, the notices are subject to the public disclosure and inspection rules generally applicable to exempt organizations. The provision does not affect an organization's obligation under present law to file required information returns or existing penalties for failure to file such returns.

The Secretary is required to notify every organization that is subject to the notice filing requirement of the new filing obligation in a timely manner. Notification by the Secretary shall be by mail, in the case of any organization the identity and address of which is included in the list of exempt organizations maintained by the Secretary, and by Internet or other means of outreach, in the case of any other organization. In addition, the Secretary is required to publicize in a timely manner in appropriate forms and instructions and other means of outreach the new penalty imposed for consecutive failures to file the information return.

The Secretary is authorized to publish a list of organizations whose exempt status is revoked under the provision.

Effective Date

The provision is effective for notices and returns with respect to annual periods beginning after 2006.

14. Disclosure to State officials relating to section 501(c) organizations (secs. 6103, 6104, 7213, 7213A, and 7431 of the Code)

Present Law

In the case of organizations that are described in section 501(c)(3) and exempt from tax under section 501(a) or that have applied for exemption as an organization so described, present law (sec. 6104(c)) requires the Secretary to notify the appropriate State officer of (1) a refusal to recognize such organization as an organization described in section 501(c)(3), (2) a revocation of a section 501(c)(3) organization's tax-exempt status, and (3) the mailing of a notice of deficiency for any tax imposed under section 507, chapter 41, or chapter 42.[457] In addition, at the request of such appropriate State officer, the Secretary is required to make available for inspection and copying, such returns, filed statements, records, reports, and other information relating to the above-described disclosures, as are relevant to any State law determination. An appropriate State officer is the State attorney general, State tax officer, or any State official charged with overseeing organizations of the type described in section 501(c)(3).

In general, returns and return information (as such terms are defined in section 6103(b)) are confidential and may not be disclosed or inspected unless expressly provided by law.[458] Present law requires the Secretary to keep records of disclosures and requests for inspection[459]

[457] The applicable taxes include the termination tax on private foundations; taxes on public charities for certain excess lobbying expenses; taxes on a private foundation's net investment income, self-dealing activities, undistributed income, excess business holdings, investments that jeopardize charitable purposes, and taxable expenditures (some of these taxes also apply to certain non-exempt trusts); taxes on the political expenditures and excess benefit transactions of section 501(c)(3) organizations; and certain taxes on black lung benefit trusts and foreign organizations.

[458] Sec. 6103(a).

[459] Sec. 6103(p)(3).

and requires that persons authorized to receive returns and return information maintain various safeguards to protect such information against unauthorized disclosure.[460] Willful unauthorized disclosure or inspection of returns or return information is subject to a fine and/or imprisonment.[461] The knowing or negligent unauthorized inspection or disclosure of returns or return information gives the taxpayer a right to bring a civil suit.[462] Such present-law protections against unauthorized disclosure or inspection of returns and return information do not apply to the disclosures or inspections, described above, that are authorized by section 6104(c).

Explanation of Provision

The provision provides that upon written request by an appropriate State officer, the Secretary may disclose: (1) a notice of proposed refusal to recognize an organization as a section 501(c)(3) organization; (2) a notice of proposed revocation of tax-exemption of a section 501(c)(3) organization; (3) the issuance of a proposed deficiency of tax imposed under section 507, chapter 41, or chapter 42; (4) the names, addresses, and taxpayer identification numbers of organizations that have applied for recognition as section 501(c)(3) organizations; and (5) returns and return information of organizations with respect to which information has been disclosed under (1) through (4) above.[463] Disclosure or inspection is permitted for the purpose of, and only to the extent necessary in, the administration of State laws regulating section 501(c)(3) organizations, such as laws regulating tax-exempt status, charitable trusts, charitable solicitation, and fraud. Such disclosure or inspection may be made only to or by an appropriate State officer or to an officer or employee of the State who is designated by the appropriate State officer, and may not be made by or to a contractor or agent. The Secretary also is permitted to disclose or open to inspection the returns and return information of an organization that is recognized as tax-exempt under section 501(c)(3), or that has applied for such recognition, to an appropriate State officer if the Secretary determines that disclosure or inspection may constitute evidence of noncompliance under the laws within the jurisdiction of the appropriate State officer. For this purpose, appropriate State officer means the State attorney general, the State tax officer, or any other State official charged with overseeing organizations of the type described in section 501(c)(3).

In addition, the provision provides that upon the written request by an appropriate State officer, the Secretary may make available for inspection or disclosure returns and return information of an organization described in section 501(c) (other than section 501(c)(1) or section 501(c)(3)). Such returns and return information are available for inspection or disclosure only for the purpose of, and to the extent necessary in, the administration of State laws regulating the solicitation or administration of the charitable funds or charitable assets of such

---

[460] Sec. 6103(p)(4).

[461] Secs. 7213 and 7213A.

[462] Sec. 7431.

[463] Such returns and return information also may be open to inspection by an appropriate State officer.

organizations. Such disclosure or inspection may be made only to or by an appropriate State officer or to an officer or employee of the State who is designated by the appropriate State officer, and may not be made by or to a contractor or agent. For this purpose, appropriate State officer means the State attorney general, the State tax officer, and the head of an agency designated by the State attorney general as having primary responsibility for overseeing the solicitation of funds for charitable purposes of such organizations.

In addition, the provision provides that any returns and return information disclosed under section 6104(c) may be disclosed in civil administrative and civil judicial proceedings pertaining to the enforcement of State laws regulating the applicable tax-exempt organization in a manner prescribed by the Secretary. Returns and return information are not to be disclosed under section 6104(c), or in such an administrative or judicial proceeding, to the extent that the Secretary determines that such disclosure would seriously impair Federal tax administration. The provision makes disclosures of returns and return information under section 6104(c) subject to the disclosure, recordkeeping, and safeguard provisions of section 6103, including through requirements that the Secretary maintain a permanent system of records of requests for disclosure (sec. 6103(p)(3)) and that the appropriate State officer maintain various safeguards that protect against unauthorized disclosure (sec. 6103(p)(4)). The provision provides that the willful unauthorized disclosure of returns or return information described in section 6104(c) is a felony subject to a fine of up to $5,000 and/or imprisonment of up to five years (sec. 7213(a)(2)), the willful unauthorized inspection of returns or return information described in section 6104(c) is subject to a fine of up to $1,000 and/or imprisonment of up to one year (sec. 7213A), and provides the taxpayer the right to bring a civil action for damages in the case of knowing or negligent unauthorized disclosure or inspection of such information (sec. 7431(a)(2)).

Effective Date

The provision is effective on the date of enactment but does not apply to requests made before such date.

15. Require that unrelated business income tax returns of section 501(c)(3) organizations be made publicly available (sec. 6104 of the Code)

Present Law

In general, an organization described in section 501(c) or (d) is required to make available for public inspection a copy of its annual information return (Form 990) and exemption application materials.[464] A penalty may be imposed on any person who does not make an organization's annual returns or exemption application materials available for public inspection. The penalty amount is $20 for each day during which a failure occurs. If more than one person fails to comply, each person is jointly and severally liable for the full amount of the penalty. The maximum penalty that may be imposed on all persons for any one annual return is $10,000. There is no maximum penalty amount for failing to make exemption application materials

[464] Sec. 6104(d).

available for public inspection. Any person who willfully fails to comply with the public inspection requirements is subject to an additional penalty of $5,000.[465]

These requirements do not apply to an organization's annual return for unrelated business income tax (generally Form 990-T).[466]

Explanation of Provision

The provision extends the present-law public inspection and disclosure requirements and penalties applicable to the Form 990 to the unrelated business income tax return (Form 990-T) of organizations described in section 501(c)(3). The provision provides that certain information may be withheld by the organization from public disclosure and inspection if public availability would adversely affect the organization, similar to the information that may be withheld under present law with respect to applications for tax exemption and the Form 990 (e.g., information relating to a trade secret, patent, process, style of work, or apparatus of the organization, if the Secretary determines that public disclosure of such information would adversely affect the organization).

Effective Date

The provision is effective for returns filed after the date of enactment.

16. Treasury study on donor advised funds and supporting organizations

Present Law

Donor advised funds

Some charitable organizations (including community foundations) establish accounts to which donors may contribute and thereafter provide nonbinding advice or recommendations with regard to distributions from the fund or the investment of assets in the fund. Such accounts are commonly referred to as "donor advised funds." Donors who make contributions to charities for maintenance in a donor advised fund generally claim a charitable contribution deduction at the time of the contribution. Although sponsoring charities frequently permit donors (or other persons appointed by donors) to provide nonbinding recommendations concerning the distribution or investment of assets in a donor advised fund, sponsoring charities generally must have legal ownership and control of such assets following the contribution. If the sponsoring charity does not have such control (or permits a donor to exercise control over amounts contributed), the donor's contributions may not qualify for a charitable deduction, and, in the case of a community foundation, the contribution may be treated as being subject to a material restriction or condition by the donor.

[465] Sec. 6685.

[466] Treas. Reg. sec. 301.6104(d)-1(b)(4)(ii).

In recent years, a number of financial institutions have formed charitable corporations for the principal purpose of offering donor advised funds, sometimes referred to as "commercial" donor advised funds. In addition, some established charities have begun operating donor advised funds in addition to their primary activities. The IRS has recognized several organizations that sponsor donor advised funds, including "commercial" donor advised funds, as section 501(c)(3) public charities. The term "donor advised fund" is not defined in statute or regulations.

Supporting organizations

The Code provides that certain "supporting organizations" (in general, organizations that provide support to another section 501(c)(3) organization that is not a private foundation) are classified as public charities rather than private foundations.[467] To qualify as a supporting organization, an organization must meet all three of the following tests: (1) it must be organized and at all times operated exclusively for the benefit of, to perform the functions of, or to carry out the purposes of one or more "publicly supported organizations"[468] (the "organizational and operational tests");[469] (2) it must be operated, supervised, or controlled by or in connection with one or more publicly supported organizations (the "relationship test");[470] and (3) it must not be controlled directly or indirectly by one or more disqualified persons (as defined in section 4946) other than foundation managers and other than one or more publicly supported organizations (the "lack of outside control test").[471]

To satisfy the relationship test, a supporting organization must hold one of three statutorily described close relationships with the supported organization. The organization must be: (1) operated, supervised, or controlled by a publicly supported organization (commonly referred to as "Type I" supporting organizations); (2) supervised or controlled in connection with a publicly supported organization ("Type II" supporting organizations); or (3) operated in connection with a publicly supported organization ("Type III" supporting organizations).[472]

Type I supporting organizations

In the case of supporting organizations that are operated, supervised, or controlled by one or more publicly supported organizations (Type I supporting organizations), one or more supported organizations must exercise a substantial degree of direction over the policies,

[467] Sec. 509(a)(3).

[468] In general, supported organizations of a supporting organization must be publicly supported charities described in sections 509(a)(1) or (a)(2).

[469] Sec. 509(a)(3)(A).

[470] Sec. 509(a)(3)(B).

[471] Sec. 509(a)(3)(C).

[472] Treas. Reg. sec. 1.509(a)-4(f)(2).

programs, and activities of the supporting organization.[473] The relationship between the Type I supporting organization and the supported organization generally is comparable to that of a parent and subsidiary. The requisite relationship may be established by the fact that a majority of the officers, directors, or trustees of the supporting organization are appointed or elected by the governing body, members of the governing body, officers acting in their official capacity, or the membership of one or more publicly supported organizations.[474]

Type II supporting organizations

Type II supporting organizations are supervised or controlled in connection with one or more publicly supported organizations. Rather than the parent-subsidiary relationship characteristic of Type I organizations, the relationship between a Type II organization and its supported organizations is more analogous to a brother-sister relationship. In order to satisfy the Type II relationship requirement, generally there must be common supervision or control by the persons supervising or controlling both the supporting organization and the publicly supported organizations.[475] An organization generally is not considered to be "supervised or controlled in connection with" a publicly supported organization merely because the supporting organization makes payments to the publicly supported organization, even if the obligation to make payments is enforceable under state law.[476]

Type III supporting organizations

Type III supporting organizations are "operated in connection with" one or more publicly supported organizations. To satisfy the "operated in connection with" relationship, Treasury regulations require that the supporting organization be responsive to, and significantly involved in the operations of, the publicly supported organization. This relationship is deemed to exist where the supporting organization meets both a "responsiveness test" and an "integral part test."[477] In general, the responsiveness test requires that the Type III supporting organization be responsive to the needs or demands of the publicly supported organizations. In general, the integral part test requires that the Type III supporting organization maintain significant involvement in the operations of one or more publicly supported organizations, and that such publicly supported organizations are in turn dependent upon the supporting organization for the type of support which it provides.

There are two alternative methods for satisfying the integral part test. The first alternative is to establish that (1) the activities engaged in for or on behalf of the publicly

[473] Treas. Reg. sec. 1.509(a)-4(g)(1)(i).

[474] Id.

[475] Treas. Reg. sec. 1.509(a)- 4(h)(1).

[476] Treas. Reg. sec. 1.509(a)-4(h)(2).

[477] Treas. Reg. sec. 1.509(a)-4(i)(1).

supported organization are activities to perform the functions of, or carry out the purposes of, such organizations; and (2) these activities, but for the involvement of the supporting organization, normally would be engaged in by the publicly supported organizations themselves.[478] Organizations that satisfy this "but for" test sometimes are referred to as "functionally integrated" Type III supporting organizations. The second method for satisfying the integral part test is to establish that: (1) the supporting organization pays substantially all of its income to or for the use of one or more publicly supported organizations;[479] (2) the amount of support received by one or more of the publicly supported organizations is sufficient to insure the attentiveness of the organization or organizations to the operations of the supporting organization (this is known as the "attentiveness requirement");[480] and (3) a significant amount of the total support of the supporting organization goes to those publicly supported organizations that meet the attentiveness requirement.[481]

Explanation of Provision

Elsewhere in the bill, provision is made for new rules with respect to donor advised funds and supporting organizations. Many issues arise under current law with respect to such organizations, some of which are addressed by the bill and some of which would benefit from additional study. The provision provides that the Secretary of the Treasury shall undertake a study on the organization and operation of donor advised funds (as defined in section 4966(d)(2)) and of supporting organizations (organizations described in section 509(a)(3)). The study shall specifically consider (1) whether the amount and availability of the income, gift, or estate tax charitable deductions allowed for charitable contributions to sponsoring organizations (as defined in section 4966(d)(1)) of donor advised funds or to organizations described in section 509(a)(3) is appropriate in consideration of (i) the use of contributed assets (including the type, extent, and timing of such use) or (ii) the use of the assets of such organizations for the benefit of the person making the charitable contribution (or a person related to such person), (2) whether donor advised funds should be required to distribute for charitable purposes a specified amount (whether based on the income or assets of the fund) in order to ensure that the sponsoring organization with respect to the fund is operating consistent with the purposes or functions constituting the basis for its exemption under section 501 or its status as an organization

---

[478] Treas. Reg. sec. 1.509(a)-4(i)(3)(ii).

[479] For this purpose, the IRS has defined the term "substantially all" of an organization's income to mean 85 percent or more. Rev. Rul. 76-208, 1976-1 C.B. 161.

[480] Although the regulations do not specify the requisite level of support in numerical or percentage terms, the IRS has suggested that grants that represent less than 10 percent of the beneficiary's support likely would be viewed as insufficient to ensure attentiveness. Gen. Couns. Mem. 36379 (August 15, 1975). As an alternative to satisfying the attentiveness standard by the foregoing method, a supporting organization may demonstrate attentiveness by showing that, in order to avoid the interruption of the carrying on of a particular function or activity, the beneficiary organization will be sufficiently attentive to the operations of the supporting organization. Treas. Reg. sec. 1.509(a)-4(i)(3)(iii)(b).

[481] Treas. Reg. sec. 1.509(a)-4(i)(3)(iii).

described in section 509(a), (3) whether the retention by donors to donor advised funds or supporting organizations of rights or privileges with respect to amounts transferred to such organizations (including advisory rights or privileges with respect to the making of grants or the investment of assets) is consistent with the treatment of such transfers as completed gifts that qualify for an income, gift, or estate tax charitable deduction, and (4) whether any of the issues addressed above also raise issues with respect to other forms of charities or charitable donations.

Not later than one year after the date of enactment of this Act, the Secretary shall submit a report on the study, comment on any actions (audits, guidance, regulations, etc.) taken by the Secretary with respect to the issues discussed in the study, and make recommendations to the Committee on Finance of the Senate and the Committee on Ways and Means of the House of Representatives.

Effective Date

The provision is effective on the date of enactment.

17. Improve accountability of donor advised funds (new secs. 4966 and 4967 of the Code)

Present Law

Requirements for section 501(c)(3) tax-exempt status

Charitable organizations, i.e., organizations described in section 501(c)(3), generally are exempt from Federal income tax and are eligible to receive tax deductible contributions. A charitable organization must operate primarily in pursuance of one or more tax-exempt purposes constituting the basis of its tax exemption.[482] In order to qualify as operating primarily for a purpose described in section 501(c)(3), an organization must satisfy the following operational requirements: (1) the net earnings of the organization may not inure to the benefit of any person in a position to influence the activities of the organization; (2) the organization must operate to provide a public benefit, not a private benefit;[483] (3) the organization may not be operated primarily to conduct an unrelated trade or business;[484] (4) the organization may not engage in substantial legislative lobbying; and (5) the organization may not participate or intervene in any political campaign.

[482] Treas. Reg. sec. 1.501(c)(3)-1(c)(1). The Code specifies such purposes as religious, charitable, scientific, testing for public safety, literary, or educational purposes, or to foster international amateur sports competition, or for the prevention of cruelty to children or animals. In general, an organization is organized and operated for charitable purposes if it provides relief for the poor and distressed or the underprivileged. Treas. Reg. sec. 1.501(c)(3)-1(d)(2).

[483] Treas. Reg. sec. 1.501(c)(3)-1(d)(1)(ii).

[484] Treas. Reg. sec. 1.501(c)(3)-1(e)(1). Conducting a certain level of unrelated trade or business activity will not jeopardize tax-exempt status.

Classification of section 501(c)(3) organizations

Section 501(c)(3) organizations are classified either as "public charities" or "private foundations."[485] Private foundations generally are defined under section 509(a) as all organizations described in section 501(c)(3) other than an organization granted public charity status by reason of: (1) being a specified type of organization (i.e., churches, educational institutions, hospitals and certain other medical organizations, certain organizations providing assistance to colleges and universities, or a governmental unit); (2) receiving a substantial part of its support from governmental units or direct or indirect contributions from the general public; or (3) providing support to another section 501(c)(3) entity that is not a private foundation. In contrast to public charities, private foundations generally are funded from a limited number of sources (e.g., an individual, family, or corporation). Donors to private foundations and persons related to such donors together often control the operations of private foundations.

Because private foundations receive support from, and typically are controlled by, a small number of supporters, private foundations are subject to a number of anti-abuse rules and excise taxes not applicable to public charities.[486] For example, the Code imposes excise taxes on acts of "self-dealing" between disqualified persons (generally, an enumerated class of foundation insiders[487]) and a private foundation. Acts of self-dealing include, for example, sales or exchanges, or leasing, of property; lending of money; or the furnishing of goods, services, or facilities between a disqualified person and a private foundation.[488] In addition, private non-operating foundations are required to pay out a minimum amount each year as qualifying distributions. In general, a qualifying distribution is an amount paid to accomplish one or more of the organization's exempt purposes, including reasonable and necessary administrative expenses.[489] Certain expenditures of private foundations are also subject to tax.[490] In general, taxable expenditures are expenditures: (1) for lobbying; (2) to influence the outcome of a public election or carry on a voter registration drive (unless certain requirements are met); (3) as a grant to an individual for travel, study, or similar purposes unless made pursuant to procedures approved by the Secretary; (4) as a grant to an organization that is not a public charity or exempt

[485] Sec. 509(a). Private foundations are either private operating foundations or private non-operating foundations. In general, private operating foundations operate their own charitable programs in contrast to private non-operating foundations, which generally are grant-making organizations. Most private foundations are non-operating foundations.

[486] Secs. 4940 - 4945.

[487] See sec. 4946(a).

[488] Sec. 4941.

[489] Sec. 4942(g)(1)(A). A qualifying distribution also includes any amount paid to acquire an asset used (or held for use) directly in carrying out one or more of the organization's exempt purposes and certain amounts set-aside for exempt purposes. Sec. 4942(g)(1)(B) and 4942(g)(2).

[490] Sec. 4945. Taxes imposed may be abated if certain conditions are met. Secs. 4961 and 4962.

operating foundation unless the foundation exercises expenditure responsibility[491] with respect to the grant; or (5) for any non-charitable purpose. Additional excise taxes may also apply in the event a private foundation holds certain business interests ("excess business holdings")[492] or makes an investment that jeopardizes the foundation's exempt purposes.[493]

Supporting organizations

The Code provides that certain "supporting organizations" (in general, organizations that provide support to another section 501(c)(3) organization that is not a private foundation) are classified as public charities rather than private foundations.[494] To qualify as a supporting organization, an organization must meet all three of the following tests: (1) it must be organized and at all times operated exclusively for the benefit of, to perform the functions of, or to carry out the purposes of one or more "publicly supported organizations"[495] (the "organizational and operational tests");[496] (2) it must be operated, supervised, or controlled by or in connection with one or more publicly supported organizations (the "relationship test");[497] and (3) it must not be controlled directly or indirectly by one or more disqualified persons (as defined in section 4946) other than foundation managers and other than one or more publicly supported organizations (the "lack of outside control test").[498]

To satisfy the relationship test, a supporting organization must hold one of three statutorily described close relationships with the supported organization. The organization must be: (1) operated, supervised, or controlled by a publicly supported organization (commonly referred to as "Type I" supporting organizations); (2) supervised or controlled in connection with a publicly supported organization ("Type II" supporting organizations); or (3) operated in connection with a publicly supported organization ("Type III" supporting organizations).[499]

---

[491] In general, expenditure responsibility requires that a foundation make all reasonable efforts and establish reasonable procedures to ensure that the grant is spent solely for the purpose for which it was made, to obtain reports from the grantee on the expenditure of the grant, and to make reports to the Secretary regarding such expenditures. Sec. 4945(h).

[492] Sec. 4943.

[493] Sec. 4944.

[494] Sec. 509(a)(3).

[495] In general, supported organizations of a supporting organization must be publicly supported charities described in sections 509(a)(1) or (a)(2).

[496] Sec. 509(a)(3)(A).

[497] Sec. 509(a)(3)(B).

[498] Sec. 509(a)(3)(C).

[499] Treas. Reg. sec. 1.509(a)-4(f)(2).

Type I supporting organizations

In the case of supporting organizations that are operated, supervised, or controlled by one or more publicly supported organizations (Type I supporting organizations), one or more supported organizations must exercise a substantial degree of direction over the policies, programs, and activities of the supporting organization.[500] The relationship between the Type I supporting organization and the supported organization generally is comparable to that of a parent and subsidiary. The requisite relationship may be established by the fact that a majority of the officers, directors, or trustees of the supporting organization are appointed or elected by the governing body, members of the governing body, officers acting in their official capacity, or the membership of one or more publicly supported organizations.[501]

Type II supporting organizations

Type II supporting organizations are supervised or controlled in connection with one or more publicly supported organizations. Rather than the parent-subsidiary relationship characteristic of Type I organizations, the relationship between a Type II organization and its supported organizations is more analogous to a brother-sister relationship. In order to satisfy the Type II relationship requirement, generally there must be common supervision or control by the persons supervising or controlling both the supporting organization and the publicly supported organizations.[502] An organization generally is not considered to be "supervised or controlled in connection with" a publicly supported organization merely because the supporting organization makes payments to the publicly supported organization, even if the obligation to make payments is enforceable under state law.[503]

Type III supporting organizations

Type III supporting organizations are "operated in connection with" one or more publicly supported organizations. To satisfy the "operated in connection with" relationship, Treasury regulations require that the supporting organization be responsive to, and significantly involved in the operations of, the publicly supported organization. This relationship is deemed to exist where the supporting organization meets both a "responsiveness test" and an "integral part test."[504] In general, the responsiveness test requires that the Type III supporting organization be responsive to the needs or demands of the publicly supported organizations. In general, the integral part test requires that the Type III supporting organization maintain significant involvement in the operations of one or more publicly supported organizations, and that such

[500] Treas. Reg. sec. 1.509(a)-4(g)(1)(i).

[501] Id.

[502] Treas. Reg. sec. 1.509(a)- 4(h)(1).

[503] Treas. Reg. sec. 1.509(a)-4(h)(2).

[504] Treas. Reg. sec. 1.509(a)-4(i)(1).

publicly supported organizations are in turn dependent upon the supporting organization for the type of support which it provides.

There are two alternative methods for satisfying the integral part test. The first alternative is to establish that (1) the activities engaged in for or on behalf of the publicly supported organization are activities to perform the functions of, or carry out the purposes of, such organizations; and (2) these activities, but for the involvement of the supporting organization, normally would be engaged in by the publicly supported organizations themselves.[505] Organizations that satisfy this "but for" test sometimes are referred to as "functionally integrated" Type III supporting organizations. The second method for satisfying the integral part test is to establish that: (1) the supporting organization pays substantially all of its income to or for the use of one or more publicly supported organizations;[506] (2) the amount of support received by one or more of the publicly supported organizations is sufficient to insure the attentiveness of the organization or organizations to the operations of the supporting organization (this is known as the "attentiveness requirement");[507] and (3) a significant amount of the total support of the supporting organization goes to those publicly supported organizations that meet the attentiveness requirement.[508]

Charitable contributions

Contributions to organizations described in section 501(c)(3) are deductible, subject to certain limitations, as an itemized deduction from Federal income taxes.[509] Such contributions also generally are deductible for estate and gift tax purposes.[510] However, if the taxpayer retains control over the assets transferred to charity, the transfer may not qualify as a completed gift for purposes of claiming an income, estate, or gift tax deduction.

Public charities enjoy certain advantages over private foundations regarding the deductibility of contributions. For example, contributions of appreciated capital gain property to

---

[505] Treas. Reg. sec. 1.509(a)-4(i)(3)(ii).

[506] For this purpose, the IRS has defined the term "substantially all" of an organization's income to mean 85 percent or more. Rev. Rul. 76-208, 1976-1 C.B. 161.

[507] Although the regulations do not specify the requisite level of support in numerical or percentage terms, the IRS has suggested that grants that represent less than 10 percent of the beneficiary's support likely would be viewed as insufficient to ensure attentiveness. Gen. Couns. Mem. 36379 (August 15, 1975). As an alternative to satisfying the attentiveness standard by the foregoing method, a supporting organization may demonstrate attentiveness by showing that, in order to avoid the interruption of the carrying on of a particular function or activity, the beneficiary organization will be sufficiently attentive to the operations of the supporting organization. Treas. Reg. sec. 1.509(a)-4(i)(3)(iii)(b).

[508] Treas. Reg. sec. 1.509(a)-4(i)(3)(iii).

[509] Sec. 170.

[510] Secs. 2055 and 2522.

a private foundation generally are deductible only to the extent of the donor's cost basis.[511] In contrast, contributions to public charities generally are deductible in an amount equal to the property's fair market value, except for gifts of inventory and other ordinary income property, short-term capital gain property, and tangible personal property the use of which is unrelated to the donee organization's exempt purpose. In addition, under present law, a taxpayer's deductible contributions generally are limited to specified percentages of the taxpayer's contribution base, which generally is the taxpayer's adjusted gross income for a taxable year. The applicable percentage limitations vary depending upon the type of property contributed and the classification of the donee organization. In general, contributions to non-operating private foundations are limited to a smaller percentage of the donor's contribution base (up to 30 percent) than contributions to public charities (up to 50 percent).[512]

In general, taxpayers who make contributions and claim a charitable deduction must satisfy recordkeeping and substantiation requirements.[513] The requirements vary depending on the type and value of property contributed. A deduction generally may be denied if the donor fails to satisfy applicable recordkeeping or substantiation requirements.

Intermediate sanctions (excess benefit transaction tax)

The Code imposes excise taxes on excess benefit transactions between disqualified persons and public charities.[514] An excess benefit transaction generally is a transaction in which an economic benefit is provided by a public charity directly or indirectly to or for the use of a disqualified person, if the value of the economic benefit provided exceeds the value of the consideration (including the performance of services) received for providing such benefit.

For purposes of the excess benefit transaction rules, a disqualified person is any person in a position to exercise substantial influence over the affairs of the public charity at any time in the five-year period ending on the date of the transaction at issue.[515] Persons holding certain powers, responsibilities, or interests (e.g., officers, directors, or trustees) are considered to be in a position to exercise substantial influence over the affairs of the public charity.

---

[511] A special rule in section 170(e)(5) provides that taxpayer are allowed a deduction equal to the fair market value of certain contributions of appreciated, publicly traded stock contributed to a private foundation.

[512] Sec. 170(b).

[513] Sec. 170(f)(8).

[514] Sec. 4958. The excess benefit transaction tax is commonly referred to as "intermediate sanctions," because it imposes penalties generally considered to be less punitive than revocation of the organization's exempt status. The tax also applies to transactions between disqualified persons and social welfare organizations (as described in section 501(c)(4)).

[515] Sec. 4958(f)(1). A disqualified person also includes certain family members of such a person, and certain entities that satisfy a control test with respect to such persons.

An excess benefit transaction tax is imposed on the disqualified person and, in certain cases, on the organization managers, but is not imposed on the public charity. An initial tax of 25 percent of the excess benefit amount is imposed on the disqualified person that receives the excess benefit. An additional tax on the disqualified person of 200 percent of the excess benefit applies if the violation is not corrected within a specified period. A tax of 10 percent of the excess benefit (not to exceed $10,000 with respect to any excess benefit transaction) is imposed on an organization manager that knowingly participated in the excess benefit transaction, if the manager's participation was willful and not due to reasonable cause, and if the initial tax was imposed on the disqualified person.

Community foundations

Community foundations generally are broadly supported section 501(c)(3) public charities that make grants to other charitable organizations located within a community foundation's particular geographic area. Donors sometimes make contributions to a community foundation through transfers to a separate trust or fund, the assets of which are held and managed by a bank or investment company.

Certain community foundations are subject to special rules that permit them to treat the separate funds or trusts maintained by the community foundation as a single entity for tax purposes. This "single entity" status allows the community foundation to be classified as a public charity. One of the requirements that community foundations must meet is that funds maintained by the community foundation may not be subject by the donor to any material restrictions or conditions. The prohibition against material restrictions or conditions is designed to prevent a donor from encumbering a fund in a manner that prevents the community foundation from freely distributing the assets and income from it in furtherance of the community foundation's charitable purposes. Under Treasury regulations, whether a particular restriction or condition placed by the donor on the transfer of assets is material must be determined from all of the facts and circumstances of the transfer. The regulations set out some of the more significant facts and circumstances to be considered in making a determination, including: (1) whether the transferee public charity is the fee owner of the assets received; (2) whether the assets are held and administered by the public charity in a manner consistent with its own exempt purposes; (3) whether the governing body of the public charity has the ultimate authority and control over the assets and the income derived from them; and (4) whether the governing body of the public charity is independent from the donor. The regulations provide several non-adverse factors for determining whether a particular restriction or condition placed by the donor on the transfer of assets is material. In addition, the regulations list numerous factors and subfactors that indicate that the community foundation is prevented from freely and effectively employing the donated assets and the income thereon.

Donor advised funds

Some charitable organizations (including community foundations) establish accounts to which donors may contribute and thereafter provide nonbinding advice or recommendations with regard to distributions from the fund or the investment of assets in the fund. Such accounts are commonly referred to as "donor advised funds." Donors who make contributions to charities for maintenance in a donor advised fund generally claim a charitable contribution deduction at the

time of the contribution. Although sponsoring charities frequently permit donors (or other persons appointed by donors) to provide nonbinding recommendations concerning the distribution or investment of assets in a donor advised fund, sponsoring charities generally must have legal ownership and control of such assets following the contribution. If the sponsoring charity does not have such control (or permits a donor to exercise control over amounts contributed), the donor's contributions may not qualify for a charitable deduction, and, in the case of a community foundation, the contribution may be treated as being subject to a material restriction or condition by the donor.

In recent years, a number of financial institutions have formed charitable corporations for the principal purpose of offering donor advised funds, sometimes referred to as "commercial" donor advised funds. In addition, some established charities have begun operating donor advised funds in addition to their primary activities. The IRS has recognized several organizations that sponsor donor advised funds, including "commercial" donor advised funds, as section 501(c)(3) public charities. The term "donor advised fund" is not defined in statute or regulations.

Under the Katrina Emergency Tax Relief Act of 2005, certain of the above-described percent limitations on contributions to public charities are temporarily suspended for purposes of certain "qualified contributions" to public charities. Under the Act, qualified contributions do not include a contribution if the contribution is for establishment of a new, or maintenance in an existing, segregated fund or account with respect to which the donor (or any person appointed or designated by such donor) has, or reasonably expects to have, advisory privileges with respect to distributions or investments by reason of the donor's status as a donor.

Excess business holdings of private foundations

Private foundations are subject to tax on excess business holdings.[516] In general, a private foundation is permitted to hold 20 percent of the voting stock in a corporation, reduced by the amount of voting stock held by all disqualified persons (as defined in section 4946). If it is established that no disqualified person has effective control of the corporation, a private foundation and disqualified persons together may own up to 35 percent of the voting stock of a corporation. A private foundation shall not be treated as having excess business holdings in any corporation if it owns (together with certain other related private foundations) not more than two percent of the voting stock and not more than two percent in value of all outstanding shares of all classes of stock in that corporation. Similar rules apply with respect to holdings in a partnership ("profits interest" is substituted for "voting stock" and "capital interest" for "nonvoting stock") and to other unincorporated enterprises (by substituting "beneficial interest" for "voting stock"). Private foundations are not permitted to have holdings in a proprietorship. Foundations generally have a five-year period to dispose of excess business holdings (acquired other than by purchase) without being subject to tax.[517] This five-year period may be extended an additional five years in limited circumstances.[518] The excess business holdings rules do not apply to

[516] Sec. 4943. Taxes imposed may be abated if certain conditions are met. Secs. 4961 and 4962.

[517] Sec. 4943(c)(6).

[518] Sec. 4943(c)(7).

holdings in a functionally related business or to holdings in a trade or business at least 95 percent of the gross income of which is derived from passive sources.[519]

The initial tax is equal to five percent of the value of the excess business holdings held during the foundation's applicable taxable year. An additional tax is imposed if an initial tax is imposed and at the close of the applicable taxable period, the foundation continues to hold excess business holdings. The amount of the additional tax is equal to 200 percent of such holdings.

Explanation of Provision

Definition of a donor advised fund

General rule

In general, the provision defines a "donor advised fund" as a fund or account that is: (1) separately identified by reference to contributions of a donor or donors (2) owned and controlled by a sponsoring organization and (3) with respect to which a donor (or any person appointed or designated by such donor (a "donor advisor") has, or reasonably expects to have, advisory privileges with respect to the distribution or investment of amounts held in the separately identified fund or account by reason of the donor's status as a donor. All three prongs of the definition must be met in order for a fund or account to be treated as a donor advised fund.

The provision defines a "sponsoring organization" as an organization that: (1) is described in section 170(c)[520] (other than a governmental entity described in section 170(c)(1), and without regard to any requirement that the organization be organized in the United States[521]); (2) is not a private foundation (as defined in section 509(a)); and (3) maintains one or more donor advised funds.

The first prong of the definition requires that a donor advised fund be separately identified by reference to contributions of a donor or donors. A distinct fund or account of a sponsoring organization does not meet this prong of the definition unless the fund or account refers to contributions of a donor or donors, such as by naming the fund after a donor, or by treating a fund on the books of the sponsoring organization as attributable to funds contributed by a specific donor or donors. Although a sponsoring organization's general fund is a "fund or account," such fund will not, as a general matter, be treated as a donor advised fund because the general funds of an organization typically are not separately identified by reference to contributions of a specific donor or donors; rather contributions are pooled anonymously within the general fund. Similarly, a fund or account of a sponsoring organization that is distinct from the organization's general fund and that pools contributions of multiple donors generally will not

[519] Sec. 4943(d)(3).

[520] Section 170(c) describes organizations to which charitable contributions that are deductible for income tax purposes can be made.

[521] See sec. 170(c)(2)(A).

meet the first prong of the definition unless the contributions of specific donors are in some manner tracked and accounted for within the fund. Accordingly, if a sponsoring organization establishes a fund dedicated to the relief of poverty within a specific community, or a scholarship fund, and the fund attracts contributions from several donors but does not separately identify or refer to contributions of a donor or donors, the fund is not a donor advised fund even if a donor has advisory privileges with respect to the fund. However, a fund or account may not avoid treatment as a donor advised fund even though there is no formal recognition of such separate contributions on the books of the sponsoring organization if the fund or account operates as if contributions of a donor or donors are separately identified. The Secretary has the authority to look to the substance of an arrangement, and not merely its form. In addition, a fund or account may be treated as identified by reference to contributions of a donor or donors if the reference is to persons related to a donor. For example, if a husband made contributions to a fund or account that in turn is named after the husband's wife, the fund is treated as being separately identified by reference to contributions of a donor.

The second prong of the definition provides that the fund be owned and controlled by a sponsoring organization. To the extent that a donor or person other than the sponsoring organization owns or controls amounts deposited to a sponsoring organization, a fund or account is not a donor advised fund. (In cases where a donor retains control of an amount provided to a sponsoring organization, there may not be a completed gift for purposes of the charitable contribution deduction.)

The third prong of the definition provides that with respect to a fund or account of a sponsoring organization, a donor or donor advisor has or reasonably expects to have advisory privileges with respect to the distribution or investment of amounts held in the fund or account by reason of a donor's status as a donor. Advisory privileges are distinct from a legal right or obligation. For example, if a donor executes a gift agreement with a sponsoring organization that specifies certain enforceable rights of the donor with respect to a gift, the donor will not be treated as having "advisory privileges" due to such enforceable rights for purposes of the donor advised fund definition.

The presence of an advisory privilege may be evident through a written document that describes an arrangement between the donor or donor adviser and the sponsoring organization whereby a donor or donor advisor may provide advice to the sponsoring organization about the investment or distribution of amounts held by a sponsoring organization, even if such privileges are not exercised. The presence of an advisory privilege also may be evident through the conduct of a donor or donor advisor and the sponsoring organization. For example, even in the absence of a writing, if a donor regularly provides advice to a sponsoring organization and the sponsoring organization regularly considers such advice, the donor has advisory privileges under the provision. Even if advisory privileges do not exist at the time of a contribution, later acts by the donor (through the provision of advice) and by the sponsoring organization (through the regular consideration of advice) may establish advisory privileges subsequent to the time of the contribution. For example, if a past donor of $100,000 telephones a sponsoring organization and states that he would like the sponsoring organization to distribute $10,000 to an organization described in section 170(b)(1)(A), although the mere act of providing advice does not establish an advisory privilege, if the sponsoring organization distributed the $10,000 to the organization specified by the donor in consideration of the donor's advice, and reinforced the donor in some

manner that future advice similarly would be considered, advisory privileges (or the reasonable expectation thereof) might be established. However, the mere provision of advice by a donor or donor advisor does not mean the donor or donor advisor has advisory privileges. For example, a donor's singular belief that he or she has advisory privileges with respect to the contribution does not establish an advisory privilege − there must be some reciprocity on the part of the sponsoring organization.

A person reasonably expects to have advisory privileges if both the donor or donor advisor and the sponsoring organization have reason to believe that the donor or donor advisor will provide advice and that the sponsoring organization generally will consider it. Thus, a person reasonably may expect to have advisory privileges even in the absence of the actual provision of advice. However, a donor's expectation of advisory privileges is not reasonable unless it is reinforced in some manner by the conduct of the sponsoring organization. If, at the time of the contribution, the sponsoring organization had no knowledge that the donor had an expectation of advisory privileges, or no intention of considering any advice provided by the donor, then the donor does not have a reasonable expectation of advisory privileges. Ultimately, the presence or absence of advisory privileges (or a reasonable expectation thereof) depends upon the facts and circumstances, which in turn depend upon the conduct (including any agreement) of both the donor or donor advisor and the sponsoring organization with respect to the making and consideration of advice.

A further requirement of the third prong is that the reasonable expectation of advisory privileges is by reason of the donor's status as a donor. Under this requirement, if a donor's reasonable expectation of advisory privileges is due solely to the donor's service to the organization, for example, by reason of the donor's position as an officer, employee, or director of the sponsoring organization, then the third prong of the definition is not satisfied. For instance, in general, a donor that is a member of the board of directors of the sponsoring organization may provide advice in his or her capacity as a board member with respect to the distribution or investment of amounts in a fund to which the board member contributed. However, if by reason of such donor's contribution to such fund, the donor secured an appointment on a committee of the sponsoring organization that advises how to distribute or invest amounts in such fund, the donor may have a reasonable expectation of advisory privileges, notwithstanding that the donor is an officer, employee, or director of the sponsoring organization.

The third prong of the definition is applicable to a donor or any person appointed or designated by such donor (the donor advisor). For purposes of this prong, a person appointed or designated by a donor advisor is treated as being appointed or designated by a donor. In addition, for purposes of any exception to the definition of a donor advised fund provided under the provision, to the extent a donor recommends to a sponsoring organization the selection of members of a committee that will advise as to distributions or investments of amounts in a fund or account of such sponsoring organization, such members are not treated as appointed or designated by the donor if the recommendation of such members by such donor is based on objective criteria related to the expertise of the member. For example, if a donor recommends that a committee of a sponsoring organization that will provide advice regarding scholarship grants for the advancement of science at local secondary schools should consist of persons who are the heads of the science departments of such schools, then the donor generally would not be

considered to have appointed or designated such persons, i.e., they would not be treated as donor advisors.

Exceptions

A donor advised fund does not include a fund or account that makes distributions only to a single identified organization or governmental entity. For example, an endowment fund owned and controlled by a sponsoring organization that is held exclusively to for the benefit of such sponsoring organization is not a donor advised fund even if the fund is named after its principal donor and such donor has advisory privileges with respect to the distribution of amounts held in the fund to such sponsoring organization. Accordingly, a donor that contributes to a university for purposes of establishing a fund named after the donor that exclusively supports the activities of the university is not a donor advised fund even if the donor has advisory privileges regarding the distribution or investment of amounts in the fund.

A donor advised fund also does not include a fund or account with respect to which a donor or donor advisor provides advice as to which individuals receive grants for travel, study, or other similar purposes, provided that (1) the donor's or donor advisor's advisory privileges are performed exclusively by such donor or donor advisor in such person's capacity as a member of a committee all of the members of which are appointed by the sponsoring organization, (2) no combination of a donor or donor advisor or persons related to such persons, control, directly or indirectly, such committee, and (3) all grants from such fund or account are awarded on an objective and nondiscriminatory basis pursuant to a procedure approved in advance by the board of directors of the sponsoring organization, and such procedure is designed to ensure that all such grants meet the requirements described in paragraphs (1), (2), or (3) of section 4945(g) (concerning grants to individuals by private foundations).

In addition, the Secretary may exempt a fund or account from treatment as a donor advised fund if such fund or account is advised by a committee not directly or indirectly controlled by a donor, donor advisor, or persons related to a donor or donor advisor. For such purposes, it is intended that indirect control includes the ability to exercise effective control. For example, if a donor, a donor advisor, and an attorney hired by the donor to provide advice regarding the donor's contributions constitute three of the five members of such a committee, the committee would be treated as being controlled indirectly by the donor for purposes of such an exception. Board membership alone does not establish direct or indirect control. In general, under this authority, the Secretary may establish rules regarding committee advised funds generally that, if followed, would result in the fund not being treated as a donor advised fund. The Secretary also may establish rules excepting certain types of committee-advised funds, such as a fund established exclusively for disaster relief, from the donor advised fund definition.

The provision also provides that the Secretary may exempt a fund or account from treatment as a donor advised fund if such fund or account benefits a single identified charitable purpose.

Deductibility of contributions to a sponsoring organization for maintenance in a donor advised fund

Contributions to certain sponsoring organizations for maintenance in a donor advised fund not eligible for a charitable deduction

Under the provision, contributions to a sponsoring organization for maintenance in a donor advised fund are not eligible for a charitable deduction for income tax purposes if the sponsoring organization is a veterans' organization described in section 170(c)(3), a fraternal society described in section 170(c)(4), or a cemetery company described in section 170(c)(5); for gift tax purposes if the sponsoring organization is a fraternal society described in section 2522(a)(3) or a veterans' organization described in section 2522(a)(4); or for estate tax purposes if the sponsoring organization is a fraternal society described in section 2055(a)(3) or a veterans' organization described in section 2055(a)(4). In addition, contributions to a sponsoring organization for maintenance in a donor advised fund are not eligible for a charitable deduction for income, gift, or estate tax purposes if the sponsoring organization is a Type III supporting organization (other than a functionally integrated Type III supporting organization). A functionally integrated Type III supporting organization is a Type III supporting organization that is not required under regulations established by the Secretary to make payments to supported organizations due to the activities of the organization related to performing the functions of, or carrying out the purposes of, such supported organizations.[522]

Additional substantiation requirements

In addition to satisfying present-law substantiation requirements under section 170(f), a donor must obtain, with respect to each charitable contribution to a sponsoring organization to be maintained in a donor advised fund, a contemporaneous written acknowledgment from the sponsoring organization providing that the sponsoring organization has exclusive legal control over the assets contributed.

Excess business holdings

The excess business holdings rules of section 4943 are applied to donor advised funds. In applying such rules, the term disqualified person means, with respect to a donor advised fund, a donor, donor advisor, a member of the family of a donor or donor advisor, or a 35 percent controlled entity of any such person. Transition rules apply to the present holdings of a donor advised fund similar to those of section 4943(c)(4)-(6).

[522] The current such regulation is Treasury regulation section 1.509(a)-4(i)(3)(ii).

Automatic excess benefit transactions, disqualified persons, taxable distributions, and more than incidental benefit

Automatic excess benefit transactions

Under the provision, any grant, loan, compensation, or other similar payment from a donor advised fund to a person that with respect to such fund is a donor, donor advisor, or a person related[523] to a donor or donor advisor automatically is treated as an excess benefit transaction under section 4958, with the entire amount[524] paid to any such person treated as the amount of the excess benefit. Other similar payments include payments in the nature of a grant, loan, or payment of compensation, such as an expense reimbursement. Other similar payments do not include, for example, a payment pursuant to bona fide sale or lease of property, which instead are subject to the general rules of section 4958 under the special disqualified person rule of the provision described below. Also as described below, payment by a sponsoring organization of, for example, compensation to a person who both is a donor with respect to a donor advised fund of the sponsoring organization and a service provider with respect to the sponsoring organization generally, will not be subject to the automatic excess benefit transaction rule of the provision unless the payment (of a grant, loan, compensation, or other similar payment) properly is viewed as a payment from the donor advised fund and not from the sponsoring organization.

Any amount repaid as a result of correcting an excess benefit transaction shall not be held in any donor advised fund.

Disqualified persons

In general, the provision provides that donors and donor advisors with respect to a donor advised fund (as well as persons related to a donor or donor advisor) are treated as disqualified persons under section 4958 with respect to transactions with such donor advised fund (though not necessarily with respect to transactions with the sponsoring organization more generally). For example, if a donor to a donor advised fund purchased securities from the fund, the purchase is subject to the rules of section 4958 because, under the provision, the donor is a disqualified person with respect to the fund. Thus, if as a result of the purchase, the donor receives an excess benefit as defined under generally applicable section 4958 rules, then the donor is subject to tax under such rules. If, as generally would be the case, the purchase was of securities that were contributed by the donor, a factor that may indicate the presence of an excess benefit is if the amount paid by the donor to acquire the securities is less than the amount the donor claimed the

[523] For purposes of the provision, a person is treated as related to another person if (1) such person bears a relationship to such other person similar to the relationships described in sections 4958(f)(1)(B) and 4958(f)(1)(C).

[524] The requirement of the provision that the entire amount of the payment be treated as the amount of the excess benefit differs from the generally applicable rule of section 4958, which provides that the excess benefit is the amount by which the value of the economic benefit provided exceeds the value of the consideration received.

securities were worth for purposes of any charitable contribution deduction of the donor. In addition, if a donor advised fund distributes securities to the sponsoring organization of the fund prior to purchase by the donor, consideration should be given to whether the distribution to the sponsoring organization prior to the purchase was intended to circumvent the disqualified person rule of the provision. If so, such a distribution may be disregarded with the result that the purchase is treated as being made from the donor advised fund and not from the sponsoring organization.

As a factual matter, a person who is a donor to a donor advised fund and thus a disqualified person with respect to the fund also may be a service provider with respect to the sponsoring organization. In general, under the provision, as under present law, the sponsoring organization's transactions with the service provider are not subject to the rules of section 4958 unless the service provider is a disqualified person with respect to the sponsoring organization (e.g., if the service provider serves on the board of directors of the sponsoring organization), or unless the transaction is not properly viewed as a transaction with the sponsoring organization but in substance is a transaction with the service provider's donor advised fund. If the transaction properly is viewed as a transaction with the donor advised fund of a sponsoring organization, then the transaction is subject to the rules of section 4958, and, as described above, if the transaction involves payment of a grant, loan, compensation, or other similar payment, then the transaction is subject to the special automatic excess benefit transaction rule of the provision. For example, if a sponsoring organization pays an amount as part of a service contract to a service provider (a bank, for example) who also is a donor to a donor advised fund of the sponsoring organization, and such amounts reasonably are charged uniformly in whole or in part as routine fees to all of the sponsoring organization's donor advised funds, the transaction generally is considered to be between the sponsoring organization and the service provider in such service provider's capacity as a service provider. The transaction is not considered to be a transaction between a donor advised fund and the service provider even though an amount paid under the contract was charged to a donor advised fund of the service provider.

The provision provides that an investment advisor (as well as persons related to the investment advisor) is treated as a disqualified person under section 4958 with respect to the sponsoring organization. Under the provision, the term "investment advisor" means, with respect to any sponsoring organization, any person (other than an employee of the sponsoring organization) compensated by the sponsoring organization for managing the investment of, or providing investment advice with respect to, assets maintained in donor advised funds (including pools of assets all or part of which are attributed to donor advised funds) owned by the sponsoring organization.

Taxable distributions

Under the provision, certain distributions from a donor advised fund are subject to tax. A "taxable distribution" is any distribution from a donor advised fund to (1) any natural person;[525]

[525] Under the provision, the term disqualified supporting organization means, with respect to any distribution from a donor advised fund: (1) a Type III supporting organization, other than a functionally integrated Type III supporting organization; and (2) any other supporting organization if either (a) the

(2) to any other person for any purpose other than one specified in section 170(c)(2)(B) (generally, a charitable purpose) or, if for a charitable purpose, the sponsoring organization does not exercise expenditure responsibility with respect to the distribution in accordance with section 4945(h). The expenditure responsibility rules generally require that an organization exert all reasonable efforts and establish adequate procedures to see that the distribution is spent solely for the purposes for which made, to obtain full and complete reports from the distributee on how the funds are spent, and to make full and detailed reports with respect to such expenditures to the Secretary. **A** taxable distribution does not in any case include a distribution to (1) an organization described in section 170(b)(1)(A)[526] (other than to a disqualified supporting organization); (2) the sponsoring organization of such donor advised fund; or (3) to another donor advised fund.[527]

In the event of a taxable distribution, an excise tax equal to 20 percent of the amount of the distribution is imposed against the sponsoring organization. In addition, an excise tax equal to five percent of the amount of the distribution is imposed against any manager of the sponsoring organization (defined in a manner similar to the term "foundation manager" under section 4945) who knowingly approved the distribution, not to exceed $10,000 with respect to any one taxable distribution. The taxes on taxable distributions are subject to abatement under generally applicable present law rules.

More than incidental benefit

Under the provision, if a donor, a donor advisor, or a person related to a donor or donor advisor of a donor advised fund provides advice as to a distribution that results in any such person receiving, directly or indirectly, a more than incidental benefit, an excise tax equal to 125 percent of the amount of such benefit is imposed against the person who advised as to the

---

donor or donor advisor of the distributing donor advised fund directly or indirectly controls a supported organization of the supporting organization, or (b) the Secretary determines by regulations that a distribution to such supporting organization otherwise is inappropriate.

[526] For purposes of the requirement that a distribution be "to" an organization described in section 170(b)(1)(A), in general, it is intended that rules similar to the rules of Treasury regulation section 53.4945-5(a)(5) apply. Under such regulations, for purposes of determining whether a grant by a private foundation is "to" an organization described in section 509(a)(1), (2), or (3) and so not a taxable expenditure under section 4945, a foreign organization that otherwise is not a section 509(a)(1), (2), or (3) organization is considered as such if the private foundation makes a good faith determination that the grantee is such an organization. Similarly, under the provision, if a sponsoring organization makes a good faith determination (under standards similar to those currently applicable for private foundations) that a distributee organization is an organization described in section 170(b)(1)(A) (other than a disqualified supporting organization), then a distribution to such organization is not considered a taxable distribution.

[527] Under the provision, sponsoring organizations may make grants to natural persons from amounts not held in donor advised funds and may establish scholarship funds that are not donor advised funds. A donor may choose to make a contribution directly to such a scholarship fund (or advise that a donor advised fund make a distribution to such a scholarship fund).

distribution, and against the recipient of the benefit. Persons subject to the tax are jointly and severally liable for the tax. In addition, if a manager of the sponsoring organization (defined in a manner similar to the term "foundation manager" under section 4945) agreed to the making of the distribution, knowing that the distribution would confer a more than incidental benefit on a donor, a donor advisor, or a person related to a donor or donor advisor, the manager is subject to an excise tax equal to 10 percent of the amount of such benefit, not to exceed $10,000. The taxes on more than incidental benefit are subject to abatement under generally applicable present law rules.

In general, under the provision, there is a more than incidental benefit if, as a result of a distribution from a donor advised fund, a donor, donor advisor, or related person with respect to such fund receives a benefit that would have reduced (or eliminated) a charitable contribution deduction if the benefit was received as part of the contribution to the sponsoring organization. If, for example, a donor advises a that a distribution from the donor's donor advised fund be made to the Girl Scouts of America, and the donor's daughter is a member of a local unit of the Girl Scouts of America, the indirect benefit the donor receives as a result of such contribution is considered incidental under the provision, as it generally would not have reduced or eliminated the donor's deduction if it had been received as part of a contribution by donor to the sponsoring organization.[528]

Reporting and disclosure

The provision requires each sponsoring organization to disclose on its information return: (1) the total number of donor advised funds it owns; (2) the aggregate value of assets held in those funds at the end of the organization's taxable year; and (3) the aggregate contributions to and grants made from those funds during the year.

In addition, when seeking recognition of its tax-exempt status, a sponsoring organization must disclose whether it intends to maintain donor advised funds. It is intended that the organization must provide information regarding its planned operation of such funds, including, for example, a description of procedures it intends to use to: (1) communicate to donors and donor advisors that assets held in donor advised funds are the property of the sponsoring organization; and (2) ensure that distributions from donor advised funds do not result in more than incidental benefit to any person.

Effective Date

The provision generally is effective for taxable years beginning after the date of enactment. The provision relating to excess benefit transactions is effective for transactions occurring after the date of enactment. Information return requirements are effective for taxable years ending after the date of enactment. The requirements concerning disclosures on an organization's application for tax exemption are effective for organizations applying for recognition of exempt status after the date of enactment. Requirements relating to charitable

[528] See, e.g., Rev. Rul. 80-77, 1980-1 C.B. 56; Rev. Proc. 90-12, 1990-1 C.B. 471.

contributions to donor advised funds are effective for contributions made after 180 days from the date of enactment.

18. Improve accountability of supporting organizations (secs. 509, 4942, 4943, 4945, 4958, and 6033 of the Code)

Present Law

Requirements for section 501(c)(3) tax-exempt status

Charitable organizations, i.e., organizations described in section 501(c)(3), generally are exempt from Federal income tax and are eligible to receive tax deductible contributions. A charitable organization must operate primarily in pursuance of one or more tax-exempt purposes constituting the basis of its tax exemption.[529] In order to qualify as operating primarily for a purpose described in section 501(c)(3), an organization must satisfy the following operational requirements: (1) the net earnings of the organization may not inure to the benefit of any person in a position to influence the activities of the organization; (2) the organization must operate to provide a public benefit, not a private benefit;[530] (3) the organization may not be operated primarily to conduct an unrelated trade or business;[531] (4) the organization may not engage in substantial legislative lobbying; and (5) the organization may not participate or intervene in any political campaign.

Section 501(c)(3) organizations (with certain exceptions) are required to seek formal recognition of tax-exempt status by filing an application with the IRS (Form 1023). In response to the application, the IRS issues a determination letter or ruling either recognizing the applicant as tax-exempt or not.

In general, organizations exempt from Federal income tax under section 501(a) are required to file an annual information return with the IRS.[532] Under present law, the information return requirement does not apply to several categories of exempt organizations. Organizations

[529] Treas. Reg. sec. 1.501(c)(3)-1(c)(1). The Code specifies such purposes as religious, charitable, scientific, testing for public safety, literary, or educational purposes, or to foster international amateur sports competition, or for the prevention of cruelty to children or animals. In general, an organization is organized and operated for charitable purposes if it provides relief for the poor and distressed or the underprivileged. Treas. Reg. sec. 1.501(c)(3)-1(d)(2).

[530] Treas. Reg. sec. 1.501(c)(3)-1(d)(1)(ii).

[531] Treas. Reg. sec. 1.501(c)(3)-1(e)(1). Conducting a certain level of unrelated trade or business activity will not jeopardize tax-exempt status.

[532] Sec. 6033(a)(1).

exempt from the filing requirement include organizations (other than private foundations), the gross receipts of which in each taxable year normally are not more than $25,000.[533]

Classification of section 501(c)(3) organizations

In general

Section 501(c)(3) organizations are classified either as "public charities" or "private foundations."[534] Private foundations generally are defined under section 509(a) as all organizations described in section 501(c)(3) other than an organization granted public charity status by reason of: (1) being a specified type of organization (i.e., churches, educational institutions, hospitals and certain other medical organizations, certain organizations providing assistance to colleges and universities, or a governmental unit); (2) receiving a substantial part of its support from governmental units or direct or indirect contributions from the general public; or (3) providing support to another section 501(c)(3) entity that is not a private foundation. In contrast to public charities, private foundations generally are funded from a limited number of sources (e.g., an individual, family, or corporation). Donors to private foundations and persons related to such donors together often control the operations of private foundations.

Because private foundations receive support from, and typically are controlled by, a small number of supporters, private foundations are subject to a number of anti-abuse rules and excise taxes not applicable to public charities.[535] For example, the Code imposes excise taxes on acts of "self-dealing" between disqualified persons (generally, an enumerated class of foundation insiders[536]) and a private foundation. Acts of self-dealing include, for example, sales or exchanges, or leasing, of property; lending of money; or the furnishing of goods, services, or facilities between a disqualified person and a private foundation.[537] In addition, private non-operating foundations are required to pay out a minimum amount each year as qualifying distributions. In general, a qualifying distribution is an amount paid to accomplish one or more of the organization's exempt purposes, including reasonable and necessary administrative

[533] Sec. 6033(a)(2); Treas. Reg. sec. 1.6033-2(a)(2)(i); Treas. Reg. sec. 1.6033-2(g)(1). Sec. 6033(a)(2)(A)(ii) provides a $5,000 annual gross receipts exception from the annual reporting requirements for certain exempt organizations. In Announcement 82-88, 1982-25 I.R.B. 23, the IRS exercised its discretionary authority under section 6033 to increase the gross receipts exception to $25,000, and enlarge the category of exempt organizations that are not required to file Form 990.

[534] Sec. 509(a). Private foundations are either private operating foundations or private non-operating foundations. In general, private operating foundations operate their own charitable programs in contrast to private non-operating foundations, which generally are grant-making organizations. Most private foundations are non-operating foundations.

[535] Secs. 4940 - 4945.

[536] See sec. 4946(a).

[537] Sec. 4941.

expenses.[538] Certain expenditures of private foundations are also subject to tax.[539] In general, taxable expenditures are expenditures: (1) for lobbying; (2) to influence the outcome of a public election or carry on a voter registration drive (unless certain requirements are met); (3) as a grant to an individual for travel, study, or similar purposes unless made pursuant to procedures approved by the Secretary; (4) as a grant to an organization that is not a public charity or exempt operating foundation unless the foundation exercises expenditure responsibility[540] with respect to the grant; or (5) for any non-charitable purpose. Additional excise taxes may apply in the event a private foundation holds certain business interests ("excess business holdings")[541] or makes an investment that jeopardizes the foundation's exempt purposes.[542]

Public charities also enjoy certain advantages over private foundations regarding the deductibility of contributions. For example, contributions of appreciated capital gain property to a private foundation generally are deductible only to the extent of the donor's cost basis.[543] In contrast, contributions to public charities generally are deductible in an amount equal to the property's fair market value, except for gifts of inventory and other ordinary income property, short-term capital gain property, and tangible personal property the use of which is unrelated to the donee organization's exempt purpose. In addition, under present law, a taxpayer's deductible contributions generally are limited to specified percentages of the taxpayer's contribution base, which generally is the taxpayer's adjusted gross income for a taxable year. The applicable percentage limitations vary depending upon the type of property contributed and the classification of the donee organization. In general, contributions to non-operating private foundations are limited to a smaller percentage of the donor's contribution base (up to 30 percent) than contributions to public charities (up to 50 percent).[544]

---

[538] Sec. 4942(g)(1)(A). A qualifying distribution also includes any amount paid to acquire an asset used (or held for use) directly in carrying out one or more of the organization's exempt purposes and certain amounts set-aside for exempt purposes. Sec. 4942(g)(1)(B) and 4942(g)(2).

[539] Sec. 4945. Taxes imposed may be abated if certain conditions are met. Secs. 4961 and 4962.

[540] In general, expenditure responsibility requires that a foundation make all reasonable efforts and establish reasonable procedures to ensure that the grant is spent solely for the purpose for which it was made, to obtain reports from the grantee on the expenditure of the grant, and to make reports to the Secretary regarding such expenditures. Sec. 4945(h).

[541] Sec. 4943.

[542] Sec. 4944.

[543] A special rule in section 170(e)(5) provides that taxpayer are allowed a deduction equal to the fair market value of certain contributions of appreciated, publicly traded stock contributed to a private foundation.

[544] Sec. 170(b).

Supporting organizations (section 509(a)(3))

The Code provides that certain "supporting organizations" (in general, organizations that provide support to another section 501(c)(3) organization that is not a private foundation) are classified as public charities rather than private foundations.[545] To qualify as a supporting organization, an organization must meet all three of the following tests: (1) it must be organized and at all times operated exclusively for the benefit of, to perform the functions of, or to carry out the purposes of one or more "publicly supported organizations"[546] (the "organizational and operational tests");[547] (2) it must be operated, supervised, or controlled by or in connection with one or more publicly supported organizations (the "relationship test");[548] and (3) it must not be controlled directly or indirectly by one or more disqualified persons (as defined in section 4946) other than foundation managers and other than one or more publicly supported organizations (the "lack of outside control test").[549]

To satisfy the relationship test, a supporting organization must hold one of three statutorily described close relationships with the supported organization. The organization must be: (1) operated, supervised, or controlled by a publicly supported organization (commonly referred to as "Type I" supporting organizations); (2) supervised or controlled in connection with a publicly supported organization ("Type II" supporting organizations); or (3) operated in connection with a publicly supported organization ("Type III" supporting organizations).[550]

Type I supporting organizations

In the case of supporting organizations that are operated, supervised, or controlled by one or more publicly supported organizations (Type I supporting organizations), one or more supported organizations must exercise a substantial degree of direction over the policies, programs, and activities of the supporting organization.[551] The relationship between the Type I supporting organization and the supported organization generally is comparable to that of a parent and subsidiary. The requisite relationship may be established by the fact that a majority of the officers, directors, or trustees of the supporting organization are appointed or elected by

[545] Sec. 509(a)(3).

[546] In general, supported organizations of a supporting organization must be publicly supported charities described in sections 509(a)(1) or (a)(2).

[547] Sec. 509(a)(3)(A).

[548] Sec. 509(a)(3)(B).

[549] Sec. 509(a)(3)(C).

[550] Treas. Reg. sec. 1.509(a)-4(f)(2).

[551] Treas. Reg. sec. 1.509(a)-4(g)(1)(i).

the governing body, members of the governing body, officers acting in their official capacity, or the membership of one or more publicly supported organizations.[552]

Type II supporting organizations

Type II supporting organizations are supervised or controlled in connection with one or more publicly supported organizations. Rather than the parent-subsidiary relationship characteristic of Type I organizations, the relationship between a Type II organization and its supported organizations is more analogous to a brother-sister relationship. In order to satisfy the Type II relationship requirement, generally there must be common supervision or control by the persons supervising or controlling both the supporting organization and the publicly supported organizations.[553] An organization generally is not considered to be "supervised or controlled in connection with" a publicly supported organization merely because the supporting organization makes payments to the publicly supported organization, even if the obligation to make payments is enforceable under state law.[554]

Type III supporting organizations

Type III supporting organizations are "operated in connection with" one or more publicly supported organizations. To satisfy the "operated in connection with" relationship, Treasury regulations require that the supporting organization be responsive to, and significantly involved in the operations of, the publicly supported organization. This relationship is deemed to exist where the supporting organization meets both a "responsiveness test" and an "integral part test."[555]

In general, the responsiveness test requires that the Type III supporting organization be responsive to the needs or demands of the publicly supported organizations. The responsiveness test may be satisfied in one of two ways.[556] First, the supporting organization may demonstrate that: (1)(a) one or more of its officers, directors, or trustees are elected or appointed by the officers, directors, trustees, or membership of the supported organization; (b) one or more members of the governing bodies of the publicly supported organizations are also officers, directors, or trustees of the supporting organization; or (c) the officers, directors, or trustees of the supporting organization maintain a close continuous working relationship with the officers,

[552] Id.

[553] Treas. Reg. sec. 1.509(a)- 4(h)(1).

[554] Treas. Reg. sec. 1.509(a)-4(h)(2).

[555] Treas. Reg. sec. 1.509(a)-4(i)(1).

[556] For an organization that was supporting or benefiting one or more publicly supported organizations before November 20, 1970, additional facts and circumstances, such as an historic and continuing relationship between organizations, also may be taken into consideration to establish compliance with either of the responsiveness tests. Treas. Reg. sec. 1.509(a)-4(i)(1)(ii).

directors, or trustees of the publicly supported organizations; and (2) by reason of such arrangement, the officers, directors, or trustees of the supported organization have a significant voice in the investment policies of the supporting organization, the timing and manner of making grants, the selection of grant recipients by the supporting organization, and otherwise directing the use of the income or assets of the supporting organization.[557] Alternatively, the responsiveness test may be satisfied if the supporting organization is a charitable trust under state law, each specified supported organization is a named beneficiary under the trust's governing instrument, and the beneficiary organization has the power to enforce the trust and compel an accounting under state law.[558]

In general, the integral part test requires that the Type III supporting organization maintain significant involvement in the operations of one or more publicly supported organizations, and that such publicly supported organizations are in turn dependent upon the supporting organization for the type of support which it provides. There are two alternative methods for satisfying the integral part test. The first alternative is to establish that (1) the activities engaged in for or on behalf of the publicly supported organization are activities to perform the functions of, or carry out the purposes of, such organizations; and (2) these activities, but for the involvement of the supporting organization, normally would be engaged in by the publicly supported organizations themselves.[559] Organizations that satisfy this "but for" test sometimes are referred to as "functionally integrated" Type III supporting organizations. The second method for satisfying the integral part test is to establish that: (1) the supporting organization pays substantially all of its income to or for the use of one or more publicly supported organizations;[560] (2) the amount of support received by one or more of the publicly supported organizations is sufficient to insure the attentiveness of the organization or organizations to the operations of the supporting organization (this is known as the "attentiveness requirement");[561] and (3) a significant amount of the total support of the supporting organization goes to those publicly supported organizations that meet the "attentiveness requirement."[562]

---

[557] Treas. Reg. sec. 1.509(a)-4(i)(2)(ii).

[558] Treas. Reg. sec. 1.509(a)-4(i)(2)(iii).

[559] Treas. Reg. sec. 1.509(a)-4(i)(3)(ii).

[560] For this purpose, the IRS has defined the term "substantially all" of an organization's income to mean 85 percent or more. Rev. Rul. 76-208, 1976-1 C.B. 161.

[561] Although the regulations do not specify the requisite level of support in numerical or percentage terms, the IRS has suggested that grants that represent less than 10 percent of the beneficiary's support likely would be viewed as insufficient to ensure attentiveness. Gen. Couns. Mem. 36379 (August 15, 1975). As an alternative to satisfying the attentiveness standard by the foregoing method, a supporting organization may demonstrate attentiveness by showing that, in order to avoid the interruption of the carrying on of a particular function or activity, the beneficiary organization will be sufficiently attentive to the operations of the supporting organization. Treas. Reg. sec. 1.509(a)-4(i)(3)(iii)(b).

[562] Treas. Reg. sec. 1.509(a)-4(i)(3)(iii).

Intermediate sanctions (excess benefit transaction tax)

The Code imposes excise taxes on excess benefit transactions between disqualified persons and public charities.[563] An excess benefit transaction generally is a transaction in which an economic benefit is provided by a public charity directly or indirectly to or for the use of a disqualified person, if the value of the economic benefit provided exceeds the value of the consideration (including the performance of services) received for providing such benefit.

For purposes of the excess benefit transaction rules, a disqualified person is any person in a position to exercise substantial influence over the affairs of the public charity at any time in the five-year period ending on the date of the transaction at issue.[564] Persons holding certain powers, responsibilities, or interests (e.g., officers, directors, or trustees) are considered to be in a position to exercise substantial influence over the affairs of the public charity.

An excess benefit transaction tax is imposed on the disqualified person and, in certain cases, on the organization managers, but is not imposed on the public charity. An initial tax of 25 percent of the excess benefit amount is imposed on the disqualified person that receives the excess benefit. An additional tax on the disqualified person of 200 percent of the excess benefit applies if the violation is not corrected within a specified period. A tax of 10 percent of the excess benefit (not to exceed $10,000 with respect to any excess benefit transaction) is imposed on an organization manager that knowingly participated in the excess benefit transaction, if the manager's participation was willful and not due to reasonable cause, and if the initial tax was imposed on the disqualified person.

Excess business holdings of private foundations

Private foundations are subject to tax on excess business holdings.[565] In general, a private foundation is permitted to hold 20 percent of the voting stock in a corporation, reduced by the amount of voting stock held by all disqualified persons (as defined in section 4946). If it is established that no disqualified person has effective control of the corporation, a private foundation and disqualified persons together may own up to 35 percent of the voting stock of a corporation. A private foundation shall not be treated as having excess business holdings in any corporation if it owns (together with certain other related private foundations) not more than two percent of the voting stock and not more than two percent in value of all outstanding shares of all classes of stock in that corporation. Similar rules apply with respect to holdings in a partnership ("profits interest" is substituted for "voting stock" and "capital interest" for "nonvoting stock") and to other unincorporated enterprises (by substituting "beneficial interest" for "voting stock").

---

[563] Sec. 4958. The excess benefit transaction tax is commonly referred to as "intermediate sanctions," because it imposes penalties generally considered to be less punitive than revocation of the organization's exempt status. The tax also applies to transactions between disqualified persons and social welfare organizations (as described in section 501(c)(4)).

[564] Sec. 4958(f)(1). A disqualified person also includes certain family members of such a person, and certain entities that satisfy a control test with respect to such persons.

[565] Sec. 4943. Taxes imposed may be abated if certain conditions are met. Secs. 4961 and 4962.

Private foundations are not permitted to have holdings in a proprietorship. Foundations generally have a five-year period to dispose of excess business holdings (acquired other than by purchase) without being subject to tax.[566] This five-year period may be extended an additional five years in limited circumstances.[567] The excess business holdings rules do not apply to holdings in a functionally related business or to holdings in a trade or business at least 95 percent of the gross income of which is derived from passive sources.[568]

The initial tax is equal to five percent of the value of the excess business holdings held during the foundation's applicable taxable year. An additional tax is imposed if an initial tax is imposed and at the close of the applicable taxable period, the foundation continues to hold excess business holdings. The amount of the additional tax is equal to 200 percent of such holdings.

Explanation of Provision

Provisions relating to all supporting organizations (Type I, Type II, and Type III)

Automatic excess benefit transactions

Under the provision, if a supporting organization (Type I, Type II, or Type III) makes a grant, loan, payment of compensation, or other similar payment to a substantial contributor (or person related to the substantial contributor) of the supporting organization, for purposes of the excess benefit transaction rules (sec. 4958), the substantial contributor is treated as a disqualified person and the payment is treated automatically as an excess benefit transaction with the entire amount of the payment treated as the excess benefit.[569] Accordingly, the substantial contributor is subject to an initial tax of 25 percent of the amount of the payment under section 4958(a)(1) and an organization manager that participated in the making of the payment, knowing that the payment was a grant, loan, payment of compensation, or other similar payment to a substantial contributor, is subject to a tax of 10 percent of the amount of the payment under section 4958(a)(2). The second tier taxes and other rules of section 4958 also apply to such payments. Other similar payments include payments in the nature of a grant, loan, or payment of compensation, such as an expense reimbursement. Other similar payments do not include, for example, a payment made pursuant to a bona fide sale or lease of property with a substantial contributor. Such payments are subject to the general rules of section 4958 if the substantial contributor meets the definition of a disqualified person under section 4958(f), but are not subject to the automatic excess benefit transaction rule of the provision. The provision applies to

[566] Sec. 4943(c)(6).

[567] Sec. 4943(c)(7).

[568] Sec. 4943(d)(3).

[569] The requirement of the provision that the entire amount of the payment be treated as the amount of the excess benefit differs from the generally applicable rule of section 4958, which provides that the excess benefit is the amount by which the value of the economic benefit provided exceeds the value of the consideration received.

payments by a supporting organization to a substantial contributor but not to payments by a substantial contributor to a supporting organization.

Under the provision, a substantial contributor means any person who contributed or bequeathed an aggregate amount of more than $5,000 to the organization, if such amount is more than two percent of the total contributions and bequests received by the organization before the close of the taxable year of the organization in which the contribution or bequest is received by the organization from such person. In the case of a trust, a substantial contributor also includes the creator of the trust. A substantial contributor does not include a public charity (other than a supporting organization). Under the provision, mechanical rules similar to the rules that apply in determining whether a person is a substantial contributor to a private foundation (secs. 509(d)(2)(B) and (C)) apply.

Under the provision, a person is a related person ("related person") if a person is a member of the family (determined under section 4958(f)(4)) of a substantial contributor, or a 35 percent controlled entity, defined as a corporation, partnership, trust, or estate in which a substantial contributor or family member thereof owns more than 35 percent of the total combined voting power, profits interest, or beneficial interest, as the case may be.

In addition, under the provision, loans by any supporting organization (Type I, Type II, or Type III) to a disqualified person (as defined in section 4958) of the supporting organization are treated as an excess benefit transaction under section 4958 and the entire amount of the loan is treated as an excess benefit. For this purpose, a disqualified person does not include a public charity (other than a supporting organization).

Disclosure requirements

Under the provision, all supporting organizations are required to file an annual information return (Form 990 series) with the Secretary, regardless of the organization's gross receipts. A supporting organization must indicate on such annual information return whether it is a Type I, Type II, or Type III supporting organization and must identify its supported organizations.

Under the provision, supporting organizations must demonstrate annually that the organization is not controlled directly or indirectly by one or more disqualified persons (other than foundation managers and other than one or more publicly supported organizations) through a certification on the annual information return. It is intended that supporting organizations be able to certify that the majority of the organization's governing body is comprised of individuals who were selected based on their special knowledge or expertise in the particular field or discipline in which the supporting organization is operating, or because they represent the particular community that is served by the supported public charities.

Disqualified person

Under the provision, for purposes of the excess benefit transaction rules (sec. 4958), a disqualified person of a supporting organization is treated as a disqualified person of the supported organization.

Provisions that apply to Type III supporting organizations

Payout with respect to Type III supporting organizations

Under the provision, the Secretary shall promulgate new regulations on payments required by Type III supporting organizations that are not functionally integrated Type III supporting organizations.[570] Such regulations shall require such organizations to make distributions of a percentage either of income or assets to the public charities they support in order to ensure that a significant amount is paid to such supported organizations. A functionally integrated Type III supporting organization is a Type III supporting organization that is not required under regulations established by the Secretary to make payments to supported organizations due to the activities of the organization related to performing the functions of, or carrying out the purposes of, such supported organizations.[571]

Excess business holdings

Under the provision, the excess business holdings rules of section 4943 are applied to Type III supporting organizations (other than functionally integrated Type III supporting organizations). In applying such rules, the term disqualified person has the meaning provided in section 4958, and also includes substantial contributors and related persons and any organization that is effectively controlled by the same person or persons who control the supporting organization or any organization substantially all of the contributions to which were made by the same person or persons who made substantially all of the contributions to the supporting organization. The excess business holdings rules do not apply if, as of November 18, 2005, the holdings were held (and at all times thereafter, are held) for the benefit of the community pursuant to the direction (made as of such date) of a State attorney general or a State official with jurisdiction over the Type III supporting organization.

---

[570] See Treas. Reg. sec. 1.509(a)-4(i)(3)(iii).

[571] The current such regulation is Treasury regulation section 1.509(a)-4(i)(3)(ii). Under Treasury regulation section 1.509(a)-4(i)(3), the integral part test of current law may be satisfied in one of two ways, one of which requires a payout of substantially all of an organization's income to or for the use of one or more publicly supported organizations, and one of which does not require such a payout. There is concern that the current income-based payout does not result in a significant amount being paid to charity if assets held by a supporting organization produce little to no income, especially in relation to the value of the assets held by the organization, and as compared to amounts paid out by nonoperating private foundations. There also is concern that the current regulatory standards for satisfying the integral part test not by reason of a payout are not sufficiently stringent to ensure that there is a sufficient nexus between the supporting and supported organizations. In revising the regulations, the Secretary has the discretion to determine whether it is appropriate to impose a pay out requirement on any or all organizations not currently required to pay out. It is intended that, in revisiting the current regulations, if the distinction between Type III supporting organizations that are required to pay out and those that are not required to pay out is retained, which may be appropriate, the Secretary nonetheless shall strengthen the standard for qualification as an organization that is not required to pay out. For example, as one requirement, the Secretary may consider whether substantially all of the activities of such an organization should be activities in direct furtherance of the functions or purposes of supported organizations.

The Secretary has the authority not to impose the excess business holdings rules if the organization establishes to the satisfaction of the Secretary that excess holdings of an organization are consistent with the purpose or function constituting the basis of the organization's exempt status. In exercising this authority, the Secretary should consider, in addition to any other factors the Secretary considers significant, as favorable, but not determinative, factors, a reasoned determination by the State attorney general with jurisdiction over the supporting organization, that disposition of the holdings would have a severe detrimental impact on the community, and a binding commitment by the supporting organization to pay out at least five percent of the value of the organization's assets each year to its supported organizations. A reasoned determination would require, among other things, evidence that any such determination was made pursuant to serious study by the State attorney general of the issues involved in disposing of the excess holdings, and findings by the State attorney general about the detrimental economic impact that would result from such disposition. If as a result of such State attorney general's study and findings, the State attorney general directed as a matter of State law that permission of the State would be required prior to any sale of the holdings, such a factor should be given strong consideration by the Secretary.

Transition rules apply to the present holdings of an organization similar to those of section 4943(c)(4)-(6).[572]

Under the provision, the excess business holdings rules also apply to Type II supporting organizations but only if such organization accepts any gift or contribution from a person (other than a public charity, not including a supporting organization) who (1) controls, directly or indirectly, either alone or together (with persons described below) the governing body of a supported organization of the supporting organization;[573] (2) is a member of the family of such a person; or (3) is a 35 percent controlled entity.

Organizational and operational requirements

[572] Under the transition rules, in general, where the existing holdings of a supporting organization and disqualified persons are in excess of 50 percent (of a voting stock interest, profits interest, or beneficial interest), and not 20 percent or 35 percent as under the general rule, but are not in excess of 75 percent, a 10-year period is available before the holdings must be reduced to 50 percent. If such holdings are more than 75 percent, the reduction to 50 percent need not occur for a 15-year period. The 15-year period is expanded to 20 years if the holdings are more than 95 percent. After the expiration of the 10, 15, or 20 year period, if disqualified persons have holdings in a business enterprise in excess of two percent of the enterprise, the supporting organization has 15 additional years to dispose of any of its own holdings that are above 25 percent of the holdings in the enterprise. If disqualified persons do not have such holdings, then the supporting organization has 15 additional years to dispose of any of its own holdings that are above 35 percent of the holdings in the enterprise.

[573] For purposes of the provision, it is intended that indirect control includes the ability to exercise effective control. For example, if a person made a gift to a supporting organization and a combination of such person, a person related to such person, and such person's personal attorney were members of the five-member board of a supported organization of the supporting organization, the organization would be treated as being indirectly controlled by such person. Board membership alone does not establish direct or indirect control.

The provision provides that, in general, after the date of enactment, a Type III supporting organization may not support an organization that is not organized in the United States.[574] But, for Type III supporting organizations that support a foreign organization on the date of enactment, the provision provides that the general rule does not apply until the first day of the third taxable year of the organization beginning after the date of enactment.

Relationship to supported organization(s)

Under the provision, a Type III supporting organization must apprise each organization it supports of information regarding the supporting organization in order to help ensure the supporting organization's responsiveness. It is intended that such a showing could be satisfied, for example, through provision of documentation such as a copy of the supporting organization's governing documents, any changes made to the governing documents, the organization's annual information return filed with the Secretary (Form 990 series), any tax return (Form 990-T) filed with the Secretary, and an annual report (including a description of all of the support provided by the supporting organization, how such support was calculated, and a projection of the next year's support). It is intended that failure to make a sufficient showing is a factor in determining whether the responsiveness test of present law is met.

In general, under the provision, a Type III supporting organization that is organized as a trust must, in addition to present law requirements, establish to the satisfaction of the Secretary, that it has a close and continuous relationship with the supported organization such that the trust is responsive to the needs or demands of the supported organization. A transition rule for existing trusts provides that the provision is not effective until one year after the date of enactment but is effective on the date of enactment for other trusts.

Other provisions

Under the provision, if a Type I or Type III supporting organization accepts any gift or contribution from a person (other than a public charity, not including a supporting organization) who (1) controls, directly or indirectly, either alone or together (with persons described below) the governing body of a supported organization of the supporting organization; (2) is a member of the family of such a person; or (3) is a 35 percent controlled entity, then the supporting organization is treated as a private foundation for all purposes until such time as the organization can demonstrate to the satisfaction of the Secretary that it qualifies as a public charity other than as a supporting organization.

Under the provision, a nonoperating private foundation may not count as a qualifying distribution under section 4942 any amount paid to (1) a Type III supporting organization that is not a functionally integrated Type III supporting organization or (2) any other supporting

[574] U.S. charities established principally to provide financial and other assistance to a foreign charity, sometimes referred to as "friends of" organizations, may not be established as supporting organizations under the provision. Such organizations may continue to obtain public charity status, however, by virtue of demonstrating broad public support (as described in sections 509(a)(1) and 509(a)(2)).

organization if a disqualified person with respect to the foundation directly or indirectly controls the supporting organization or a supported organization of such supporting organization. Any amount that does not count as a qualifying distribution under this rule is treated as a taxable expenditure under section 4945.

Effective Date

The provision generally is effective on the date of enactment. The excess benefit transaction rules are effective for transactions occurring after July 25, 2006 (except that the rule relating to the definition of a disqualified person is effective for transactions occurring after the date of enactment). The excess business holdings requirements are effective for taxable years beginning after the date of enactment. The provision relating to distributions by nonoperating private foundations is effective for distributions and expenditures made after the date of enactment. The return requirements are effective for returns filed for taxable years ending after the date of enactment.

TITLE XIII: OTHER PROVISIONS

A. Technical Corrections to Mine Safety Act[575]

The bill makes technical corrections to the Mine Improvement and New Emergency Response Act ("MINER Act") of 2006 (Pub. L. No. 109-236). Specifically, the provision corrects a drafting error by recodifying the MINER Act's provisions increasing criminal penalties under the Mine Safety and Health Act at 30 U.S.C. s. 820(d), as was intended, and makes other technical and conforming changes.

B. Going To The Sun Road

Present Law

Section 1940 of the Safe, Accountable, Flexible, Efficient Transportation Equity Act: a Legacy for Users ("SAFETEA-LU") provides authorization for the appropriation of $50 million in funding for work to resurface, repair, rehabilitate and reconstruct the Going to the Sun Road at Glacier National Park Montana ($10 million per year for fiscal years 2005 through 2009).

Section 10212 of SAFETEA-LU rescinds a specified amount of unobligated balances of funds apportioned before September 30, 2009, to States for the Interstate maintenance, national highway system, bridge, congestion mitigation and air quality improvement, surface transportation (other than the STP set-aside programs), metropolitan planning, minimum guarantee, Appalachian development highway system, recreational trails, safe routes to school, freight intermodal connectors, coordinated border infrastructure, high risk rural road, and highway safety improvement programs. The specified amount is $8,543,000,000.

Explanation of Provision

The provision eliminates the authorizations for fiscal years 2005 and 2006, and redistributes those funds as $16,666,666 per year for fiscal years 2007 through 2009. The provision further provides that funds authorized to be appropriated under the provision are contract authority to be available for obligation in the same manner as if the funds were apportioned under chapter 1 of title 23 of the United States Code. The provision increases by $50 million the specified amount subject to rescission from $8,543,000,000 to $8,593,000,000.

Effective Date

The provision is effective on the date of enactment.

---

[575] The description of these provisions, which do not amend the Internal Revenue Code of 1986, was provided to the staff of the Joint Committee on Taxation by staff of the House Committee on Education and the Workforce.

C. Exception to Local Furnishing Requirements for Certain Alaska Hydroelectric Projects

Present Law

Interest on bonds issued by State and local governments generally is excluded from gross income for Federal income tax purposes if the proceeds of such bonds are used to finance direct activities of governmental units or if such bonds are repaid with revenues of governmental units. Interest on State or local government bonds issued to finance activities of private persons is taxable unless a specific exception applies ("private activity bonds").

The interest on private activity bonds is eligible for tax-exemption if such bonds are issued for certain purposes permitted by the Code ("qualified private activity bonds"). The definition of a qualified private activity bond includes bonds issued to finance certain private facilities for the "local furnishing" of electricity or gas. Generally, a facility provides local furnishing if the area served by the facility does not exceed (1) two contiguous counties or (2) a city and a contiguous county (the "two-county rule").

The Code generally limits the local furnishing exception to bonds for facilities (1) of persons who were engaged in the local furnishing of electric energy or gas on January 1, 1997 (or a successor in interest to such persons), and (2) that serve areas served by those persons on such date (the "service area limitation") (sec. 142(f)(3)). The Small Business Job Protection Act of 1996 (the "Act") provided an exception from these limitations for bonds issued to finance the acquisition of the Snettisham hydroelectric project from the Alaska Power Administration (Pub. L. No. 104-188, sec. 1804 (1996)).

Explanation of Provision

The provision provides an exception from the service area limitation under section 142(f)(3) for bonds issued prior to May 31, 2006, to finance the Lake Dorothy hydroelectric project to provide electricity to the City of Hoonah, Alaska. In addition, the furnishing of electric service to the City of Hoonah, Alaska is disregarded for purposes of applying the two-county rule to bonds issued before May 31, 2006, to finance either the Lake Dorothy hydroelectric project (as defined in the provision) or to finance the acquisition of the Snettisham hydroelectric project.

Effective Date

The provision is effective on the date of enactment.

D. Extend Certain Tax Rules for Qualified Tuition Programs (sec. 529 of the Code)

Present Law

Overview

Section 529 provides specified income tax and transfer tax rules for the treatment of accounts and contracts established under qualified tuition programs.[576] A qualified tuition program is a program established and maintained by a State or agency or instrumentality thereof, or by one or more eligible educational institutions, which satisfies certain requirements and under which a person may purchase tuition credits or certificates on behalf of a designated beneficiary that entitle the beneficiary to the waiver or payment of qualified higher education expenses of the beneficiary (a "prepaid tuition program").[577] In the case of a program established and maintained by a State or agency or instrumentality thereof, a qualified tuition program also includes a program under which a person may make contributions to an account that is established for the purpose of satisfying the qualified higher education expenses of the designated beneficiary of the account, provided it satisfies certain specified requirements (a "savings account program").[578] Under both types of qualified tuition programs, a contributor establishes an account for the benefit of a particular designated beneficiary to provide for that beneficiary's higher education expenses.

For this purpose, qualified higher education expenses means tuition, fees, books, supplies, and equipment required for the enrollment or attendance of a designated beneficiary at an eligible educational institution, and expenses for special needs services in the case of a special needs beneficiary that are incurred in connection with such enrollment or attendance.[579] Qualified higher education expenses generally also include room and board for students who are enrolled at least half-time.[580]

Income tax treatment

A qualified tuition program, including a savings account or a prepaid tuition contract established thereunder, generally is exempt from income tax, although it is subject to the tax on unrelated business income.[581] Contributions to a qualified tuition account (or with respect to a

---

[576] The term "account" refers to a prepaid tuition benefit contract or a tuition savings account established pursuant to a qualified tuition program.

[577] Sec. 529(b)(1)(A).

[578] Sec. 529(b)(1)(A).

[579] Sec. 529(e)(3)(A).

[580] Sec. 529(e)(3)(B).

[581] Sec. 529(a). An interest in a qualified tuition account is not treated as debt for purposes of the debt-financed property rules under section 514. Sec. 529(e)(4).

prepaid tuition contract) are not deductible to the contributor or includible in income of the designated beneficiary or account owner. Earnings accumulate tax-free until a distribution is made. If a distribution is made to pay qualified higher education expenses, no portion of the distribution is subject to income tax.[582] If a distribution is not used to pay qualified higher education expenses, the earnings portion of the distribution is subject to Federal income tax[583] and a 10-percent additional tax (subject to exceptions for death, disability, or the receipt of a scholarship).[584] A change in the designated beneficiary of an account or prepaid contract is not treated as a distribution for income tax purposes if the new designated beneficiary is a member of the family of the old beneficiary.[585]

Gift and generation-skipping transfer (GST) tax treatment

A contribution to a qualified tuition account (or with respect to a prepaid tuition contract) is treated as a completed gift of a present interest from the contributor to the designated beneficiary.[586] Such contributions qualify for the per-donee annual gift tax exclusion ($12,000 for 2006), and, to the extent of such exclusions, also are exempt from the generation-skipping transfer (GST) tax. A contributor may contribute in a single year up to five times the per-donee annual gift tax exclusion amount to a qualified tuition account and, for gift tax and GST tax purposes, treat the contribution as having been made ratably over the five-year period beginning with the calendar year in which the contribution is made.[587]

A distribution from a qualified tuition account or prepaid tuition contract generally is not subject to gift tax or GST tax.[588] Those taxes may apply, however, to a change of designated

[582] Sec. 529(c)(3)(B). Any benefit furnished to a designated beneficiary under a qualified tuition account is treated as a distribution to the beneficiary for these purposes. Sec. 529(c)(3)(B)(iv).

[583] Sec. 529(c)(3)(A) and (B)(ii).

[584] Sec. 529(c)(6).

[585] Sec. 529(c)(3)(C)(ii). For this purpose, "member of the family" means, with respect to a designated beneficiary: (1) the spouse of such beneficiary; (2) an individual who bears a relationship to such beneficiary which is described in paragraphs (1) through (8) of section 152(a) (i.e., with respect to the beneficiary, a son, daughter, or a descendant of either; a stepson or stepdaughter; a sibling or stepsibling; a father, mother, or ancestor of either; a stepfather or stepmother; a son or daughter of a brother or sister; a brother or sister of a father or mother; and a son-in-law, daughter-in-law, father-in-law, mother-in-law, brother-in-law, or sister-in-law), or the spouse of any such individual; and (3) the first cousin of such beneficiary. Sec. 529(e)(2).

[586] Sec. 529(c)(2)(A).

[587] Sec. 529(c)(2)(B).

[588] Sec. 529(c)(5)(A).

beneficiary if the new designated beneficiary is in a generation below that of the old beneficiary or if the new beneficiary is not a member of the family of the old beneficiary.[589]

Estate tax treatment

Qualified tuition program account balances or prepaid tuition benefits generally are excluded from the gross estate of any individual.[590] Amounts distributed on account of the death of the designated beneficiary, however, are includible in the designated beneficiary's gross estate.[591] If the contributor elected the special five-year allocation rule for gift tax annual exclusion purposes, any amounts contributed that are allocable to the years within the five-year period remaining after the year of the contributor's death are includible in the contributor's gross estate.[592]

Certain provisions expiring under the Economic Growth and Tax Relief Reconciliation Act of 2001 ("EGTRRA")

The Economic Growth and Tax Relief Reconciliation Act of 2001 ("EGTRRA") made a number of changes to the rules regarding qualified tuition programs. However, in order to comply with reconciliation procedures under the Congressional Budget Act of 1974, EGTRRA included a "sunset" provision, pursuant to which the provisions of the Act expire at the end of 2010. Specifically, EGTRRA's provisions do not apply for taxable, plan, or limitation years beginning after December 31, 2010, or to estates of decedents dying after, or gifts or generation-skipping transfers made after, December 31, 2010. EGTRRA provides that, as of the effective date of the sunset, the Code will be applied as thought EGTRRA had never been enacted.

The provisions of present-law section 529 scheduled to expire by reason of the EGTRRA sunset provision include: (1) the provision that makes qualified withdrawals from qualified tuition accounts exempt from income tax; (2) the repeal of a pre-EGTRRA requirement that there be more than a de minimis penalty imposed on amounts not used for educational purposes and the imposition of the 10-percent additional tax on distributions not used for qualified higher education purposes; (3) a provision permitting certain private educational institutions to establish prepaid tuition programs that qualify under section 529 if they receive a ruling or determination to that effect from the Internal Revenue Service, and if the assets are held in a trust created or organized for the exclusive benefit of designated beneficiaries; (4) certain provisions permitting rollovers from one account to another account; (5) certain rules regarding the treatment of room and board as qualifying expenses; (6) certain rules regarding coordination with Hope and lifetime learning credit provisions; (7) the provision that treats first cousins as members of the

[589] Sec. 529(c)(5)(B).

[590] Sec. 529(c)(4)(A).

[591] Sec. 529(c)(4)(B).

[592] Sec. 529(c)(4)(C).

family for purposes of the rollover and change in beneficiary rules; and (8) certain provisions regarding the education expenses of special needs beneficiaries.[593]

Explanation of Provision

Permanently extend EGTRRA modifications to qualified tuition program rules

The provision repeals the sunset provision of EGTRRA insofar as it applies to the EGTRRA modifications to the rules regarding qualified tuition programs. As a result, the provision permanently extends all provisions of EGTRRA that expire at the end of 2010 that relate to qualified tuition programs.

Grant of regulatory authority to Treasury

Present law regarding the transfer tax treatment of qualified tuition program accounts is unclear and in some situations imposes tax in a manner inconsistent with generally applicable transfer tax provisions. In addition, present law creates opportunities for abuse of qualified tuition programs. For example, taxpayers may seek to avoid gift and generation skipping transfer taxes by establishing and contributing to multiple qualified tuition program accounts with different designated beneficiaries (using the provision of section 529 that permits a contributor to contribute up to five times the annual exclusion amount per donee in a single year and treat the contribution as having been made ratably over five years), with the intention of subsequently changing the designated beneficiaries of such accounts to a single, common beneficiary and distributing the entire amount to such beneficiary without further transfer tax consequences. Taxpayers also may seek to use qualified tuition program accounts as retirement accounts with all of the tax benefits but none of the restrictions and requirements of qualified retirement accounts. The provision grants the Secretary broad regulatory authority to clarify the tax treatment of certain transfers and to ensure that qualified tuition program accounts are used for the intended purpose of saving for higher education expenses of the designated beneficiary, including the authority to impose related recordkeeping and reporting requirements. The provision also authorizes the Secretary to limit the persons who may be contributors to a qualified tuition program and to determine any special rules for the operation and Federal tax consequences of such programs if such contributors are not individuals.

Effective Date

The provision is effective on the date of enactment.

[593] EGTRRA sec. 402.

TITLE XIV: TARIFF PROVISIONS[594]

A. Suspension of Duties on Liquid Crystal Device (LCD) Panel Assemblies for Use in LCD Direct View Televisions

Present Law

Present law provides for a 4.5 percent ad valorem customs duty on imported liquid crystal device (LCD) panel assemblies for use in LCD direct view televisions from all sources (provided for in subheading 9013.80.90 of the Harmonized Tariff Schedule of the United States).

Explanation of Provision

The provision suspends the present customs duty applicable to LCD panel assemblies for use in LCD direct view televisions through December 31, 2009.

Effective Date

The provision applies with respect to goods entered, or withdrawn from warehouse for consumption, on or after the 15th day after the date of the enactment.

B. Suspension of Duties on Ceiling Fans

Present Law

Present law provides for a 4.7-percent ad valorem customs duty on imported ceiling fans from all sources (provided for in subheading 8414.51.00 of the Harmonized Tariff Schedule of the United States), but that duty is currently suspended for all imports until December 31, 2006.

Explanation of Provision

The provision extends the current suspension of the customs duty applicable to ceiling fans through December 31, 2009.

Effective Date

The provision applies with respect to goods entered, or withdrawn from warehouse for consumption, on or after the 15th day after the date of the enactment.

---

[594] The description of these provisions, which do not amend the Internal Revenue Code of 1986, was provided to the staff of the Joint Committee on Taxation by staff of the House Committee on Ways and Means and the Senate Committee on Finance.

C. Suspension of Duties on Nuclear Steam Generators, Reactor Vessel Heads and Pressurizers

Present Law

Nuclear steam generators, as classified under heading 9902.84.02 of the Harmonized Tariff Schedule of the United States, enter the United States duty free until December 31, 2008. After December 31, 2008, the duty on nuclear steam generators returns to the column 1 rate of 5.2 percent under subheading 8402.11.00 of the Harmonized Tariff Schedule of the United States.

Nuclear reactor vessel heads and pressurizers, as classified under heading 9902.84.03 of the Harmonized Tariff Schedule of the United States, enter the United States duty free until December 31, 2008. After December 31, 2008, the duty on nuclear reactor vessel heads and pressurizers returns to the column 1 rate of 3.3 percent under subheading 8401.40.00 of the Harmonized Tariff Schedule of the United States.

Explanation of Provision

With respect to imported nuclear steam generators, reactor vessel heads, and pressurizers, that are purchased pursuant to a contract entered into on or before July 31, 2006, the provision extends the present-law suspension of applicable customs duty through December 31, 2010.

Effective Date

The provision is effective with respect to goods entered, or withdrawn from warehouse for consumption, on or after the 15th day after the date of enactment.

D. Suspension of New Shipper Bonding Privilege

Present Law

Once an antidumping or countervailing duty order is in place, importers of subject merchandise are required to post cash deposits to cover the estimated duties. An exception is made for importers of subject merchandise from new shippers (foreign producers or exporters) who were not selling to the United States at the time of the original investigation and who have requested a review of their shipments to determine individual dumping margins or countervailing duty rates. During the pendency of such a review, an importer of subject merchandise from a new shipper may choose to post a bond or security in lieu of a cash deposit of estimated duties.

Explanation of Provision

The provision temporarily suspends the ability of importers of subject merchandise from new shippers to choose to post a bond or security in lieu of a cash deposit of estimated duties during the period beginning on April 1, 2006, through June 30, 2009.

The provision requires the Secretary of the Treasury, in consultation with the Secretary of Commerce and the Secretary of Homeland Security, to submit to the Committee on Ways and Means of the House of Representatives and the Committee on Finance of the Senate a report describing: (1) any major problem encountered in the collection of duties, including any fraudulent activity intended to avoid the payment of duties; (2) an estimate of duties that were uncollected and a description of why the duties were uncollected; and (3) recommendations on any additional action needed to address problems related to the collection of duties.

In addition, the provision requires the Secretary of the Treasury, in consultation with the Secretary of Commerce, the United States Trade Representative, and the Secretary of Homeland Security, to submit to the Committee on Ways and Means of the House of Representatives and the Committee on Finance of the Senate a report containing: (1) recommendations on whether the temporary suspension of the new shipper bonding privilege should be extended beyond June 30, 2009; (2) an assessment of the effectiveness of any administrative measure taken to address problems encountered in the collection of duties from importers of subject merchandise from new shippers; and (3) an assessment of any burden imposed on legitimate trade and commerce by the temporary suspension of the new shipper bonding privilege.

Effective Date

The provision is effective on the date of enactment, and it applies to imports from new shippers during the period beginning on April 1, 2006, through June 30, 2009.

E. Wool Trust Fund and Wool Fabric Duty Suspension

Present Law

Present law enacted in the Trade Act of 2002 and extended in the Miscellaneous Trade Bill of 2004 provides for temporary duty reductions or duty suspensions of certain fabrics made from worsted wool and for payments made under the wool trust fund. The fund consists of three special refund pools for importers of wool fabric, wool yarn, and wool fiber and top, and identifies all persons eligible for the refunds including U.S. manufacturers of these products. The program expires in 2007.

Explanation of Provision

The provision extends the current program for an additional two years until 2009.

Effective Date

The provision is effective on the date of enactment.

F. Miscellaneous Trade and Technical Corrections Provisions

Present Law

Under present law, imports of the goods described in Title I of Division B of the bill enter under the specified Harmonized Tariff Schedule subheading with the associated tariff rate.

Explanation of Provision

The bill includes certain provisions taken from the House-passed H.R. 4944, the Miscellaneous Trade and Technical Corrections Act of 2006, for which there are Senate companions introduced, which suspend or reduce the tariff rate on certain selected products. The provisions also correct government errors or authorize reliquidations of duties related to certain products.

Effective Date

The effective date is the 15th day after the date of enactment.

G. Vessel Repair Duties

Present law

Under present law, section 466(h) of the Tariff Act of 1930 (19 U.S.C. 1466(h)), the cost of equipment, repair parts, and materials that are installed on a vessel documented under the laws of the United States and engaged in the foreign or coasting trade, if the installation is done by members of the regular crew of such vessel while the vessel is on the high seas, is excluded from a 50 percent ad valorem duty.

Explanation of Provision

This provision clarifies that the 50 percent ad valorem duty on vessel repairs excludes the cost of equipment, repair parts, and materials that are installed on a vessel documented under the laws of the United States and engaged in the foreign or coasting trade, if the installation is done by members of the regular crew of such vessel while the vessel is on the high seas, in foreign waters, or in a foreign port, and does not involve foreign shipyard repairs by foreign labor.

Effective Date

The provision is effective on the date of enactment, and it applies to vessel equipment, repair parts, and materials installed on or after April 25, 2001.

H. CAFTA-DR Provisions Related to Agreement Implementation

Present Law

Present law enacted in the Dominican Republic-Central America-United States Free Trade Agreement (CAFTA-DR) Implementation Act allows the President to exercise proclamation authority to implement provisions of the Agreement including tariffs and rules of origin changes, except for rules of origin changes for certain textile and apparel items. Also, current law was drafted under the assumption at the time of enactment of this legislation that the entry into force for all CAFTA-DR countries would be identical including for the purpose of determining the rule of origin covering co-produced products.

Explanation of Provision

The provision extends narrow proclamation authority to the President to implement specific proposed changes to the rules of origin for certain apparel items and certain trade preference level administrative changes as embodied in letters of understanding between the United States and several of the CAFTA-DR countries. For those countries that have not implemented the Agreement and have not negotiated letters of understanding with the United States for rules of origin changes, the provision grants limited proclamation authority to the President to proclaim changes yet to be agreed upon related to rules of origin for articles containing pocketing material, but the President's authority is subject to consultation and layover requirements and Congressional disapproval action. These limitations are considered appropriate given the extraordinary nature of granting open-ended proclamation authority to a President in this sensitive product area.

In addition, the provision provides a technical correction with respect to application of a retroactive effective date for certain liquidations and reliquidations of co-produced products. The provision also creates a reporting requirement for the U.S. Trade Representative's Office on the status of negotiations related to other CAFTA-DR textile changes concerning socks and technical corrections.

Effective Date

The effective date is the date of enactment, and the apparel proclamation authority extends until December 31, 2007.

Total investment needs
$255 BILLION

Estimated spending
$146.4 BILLION

Projected shortfall
$108.6 BILLION

CONDITIONS

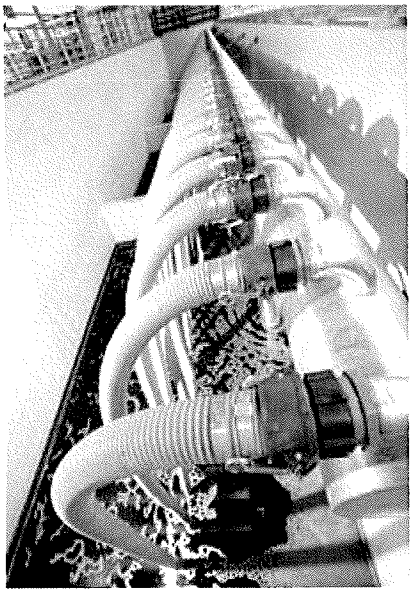
The nation's drinking-water systems face staggering public investment needs over the next 20 years. Although America spends billions on infrastructure each year, drinking water systems face an annual shortfall of at least $11 billion in funding needed to replace aging facilities that are near the end of their useful life and to comply with existing and future federal water regulations. The shortfall does not account for any growth in the demand for drinking water over the next 20 years.[2]

Of the nearly 53,000 community water systems, approximately 83% serve 3,300 or fewer people. These systems provide water to just 9% of the total U.S. population served by all community systems. In contrast, 8% of community water systems serve more than 10,000 people and provide water to 81% of the population served. Eighty-five percent (16,348) of nontransient, noncommunity water systems and 97% (83,351) of transient noncommunity water systems serve 500 or fewer people. These smaller systems face huge financial, technological, and managerial challenges in meeting a growing number of federal drinking-water regulations.

In 2002, the U.S. Environmental Protection Agency (EPA) issued The Clean Water and Drinking Water Infrastructure Gap Analysis, which identified potential funding gaps between projected needs and spending from 2000 through 2019. This analysis estimated a potential 20-year funding gap for drinking water capital expenditures as well as operations and maintenance, ranging from $45 billion to $263 billion, depending on spending levels. Capital needs alone were pegged at $161 billion.[2]

The Congressional Budget Office (CBO) concluded in 2003 that "current funding from all levels of government and current revenues generated from ratepayers will not be sufficient to meet the nation's future demand for water infrastructure." The CBO estimated the nation's needs for drinking water investments at between $10 billion and $20 billion over the next 20 years.[3]

In 1996, Congress enacted the drinking-water state revolving loan fund (SRF) program. The program authorizes the EPA to award annual capitalization grants to states. States then use their grants (plus a 20% state match) to provide loans and other assistance to public water systems. Communities repay loans into the fund, thus replenishing the fund and making resources available for projects in other communities. Eligible projects include installation and replacement of treatment facilities, distribution systems, and some storage facilities. Projects to replace aging infrastructure are eligible if they are needed to maintain compliance or to further public health protection goals.



Federal assistance has not kept pace with demand, however. Between FY 1997 and FY 2008, Congress appropriated approximately $9.5 billion for the SRF. This 11-year total is only slightly more than the annual capital investment gap for each of those years as calculated by the EPA in 2002.

CASE STUDIES

ORANGE COUNTY, CA ★ Groundwater Replenishment System

The California Department of Water Resources predicts that by 2020, the entire state will experience water shortages equal to the needs of 4 to 12 million families of four for one year. To meet growing demand and reduce reliance on water imported from northern California and the Colorado River, the Orange County Water District developed the Groundwater Replenishment (GWR) System that takes highly treated sewer water and purifies it to levels that meet state and federal drinking water standards. GWR System water will be between 35% to 75% cheaper than water produced by seawater desalination and the purification process will consume about half the energy. *Photos courtesy of Orange County Water District.*

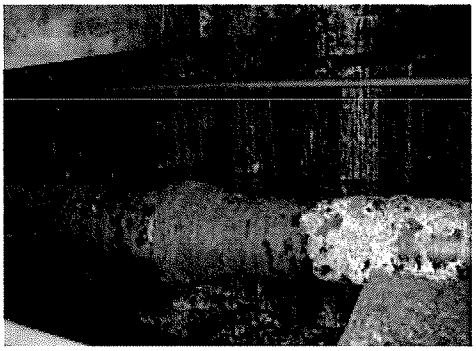
RESILIENCE

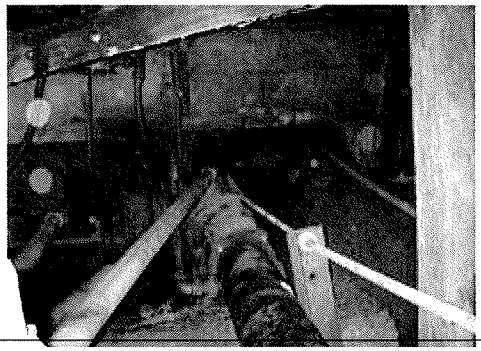
Drinking water systems provide a critical public health function and are essential to life, economic development, and growth. Disruptions in service can hinder disaster response and recovery efforts, expose the public to water-borne contaminants, and cause damage to roadways, structures, and other infrastructure, endangering lives and resulting in billions of dollars in losses.

The nation's drinking-water systems are not highly resilient; present capabilities to prevent failure and properly maintain or reconstitute services are inadequate. Additionally, the lack of investment and the interdependence on the energy sector contribute to the lack of overall system resilience. These shortcomings are currently being addressed through the construction of dedicated emergency power generation at key drinking water utility facilities, increased connections with adjacent utilities for emergency supply, and the development of security and criticality criteria. Investment prioritization must take into consideration system vulnerabilities, interdependencies, improved efficiencies in water usage via market incentives, system robustness, redundancy, failure consequences, and ease and cost of recovery.

The question is not whether the federal government should take more responsibility for drinking water improvements but how it should take more responsibility.



RAISING THE GRADES
CASE STUDIES



LOUISVILLE, KY ★ American Recovery and Reinvestment Act Funding

The Louisville Water Company has proposed $11 million in projects that could be funded as part of the 2009 American Recovery and Reinvestment Act (P.L. 111-005). The projects would rehabilitate 75 miles of water main to extend the useful life of the system and reduce water main breaks. In addition, 9.5 miles of water main would be replaced to improve water quality, fire hydrant flow and reduce maintenance. Together, the projects would support 101 jobs.

PORT ANGELES, WA ★ Downtown Water Main Project

In 2008, the City of Port Angeles completed a project to replace the water mains and sidewalks in the downtown area. The replacement water mains bring the city's downtown area to a service level that meets current fire flow standards, reduces seismic risks and helps prevent water main failures due to age. The original water mains were installed in 1914. In conjunction with the water main replacement, many sidewalks were replaced with pavers that enhance the downtown appearance. Also, new conduit and wiring was installed for street and pedestrian lighting. *Photos courtesy of the City of Port Angeles.*

CONCLUSION

New solutions are needed for what amounts to nearly $1 trillion in critical drinking water and wastewater investments over the next two decades. Not meeting the investment needs of the next 20 years risks reversing public health, environmental, and economic gains of the past three decades.

Without a significantly enhanced federal role in providing assistance to drinking water infrastructure, critical investments will not occur. Possible solutions include grants, trust funds, loans and incentives for private investment. The question is not whether the federal government should take more responsibility for drinking water improvements but how it should take more responsibility.

The case for federal investment is compelling. Needs are large and unprecedented; in many locations, local sources cannot be expected to meet this challenge alone, and because waters are shared across local and state boundaries, the benefits of federal help will accrue to the entire nation. Clean and safe water is no less a national priority than are national defense, an adequate system of interstate highways, and a safe and efficient aviation system. These latter infrastructure programs enjoy sustainable, long-term federal grant programs; under current policy, water and wastewater infrastructure do not. ★

BEFORE THE TENNESSEE REGULATORY AUTHORITY

NASHVILLE, TENNESSEE
April 27, 2012

IN RE:	)	
	)	
PETITION OF TENNESSEE AMERICAN WATER	)	**DOCKET NO.**
COMPANY FOR A GENERAL RATE INCREASE	)	**10-00189**

CONCURRENCE AND DISSENT OF DIRECTOR ROBERSON

On April 4, 2011, the voting panel assigned to this docket convened to consider the *Petition* filed by Tennessee American Water Company ("TAWC" or the "Company"). At the conclusion of the deliberations, a majority[1] of the panel concluded that TAWC should be granted an annual revenue increase of $5,551,013, or an overall rate increase of 14.98%. For the reasons set forth below, I respectfully dissent.

Regulation must serve in the stead of competition and market forces. The Authority is, of course, obligated to set rates that are "just and reasonable"[2] and a fair rate of return on a company's investments while ensuring the safety and reliability of the service offered.[3] But I believe that it is incumbent upon us as regulators to reflect current market conditions and economic realities in making our decisions as to exactly what constitutes a "just and reasonable" rate or a "fair" rate of return.

---

[1] Chairman Freeman presented her pre-filed motion, with which Director Kyle concurred.
[2] *See* Tenn. Code Ann. § 65-5-101(a) (Supp. 2010).
[3] *See Bluefield Water Works & Improvement Co. v. P.S.C. of West Virginia*, 262 U.S. 679 (1923) and *F.P.C. v. Hope Natural Gas Co.*, 320 U.S. 591 (1944).

The majority approved 110 employees for TAWC, an increase from the 109 employees approved in the 2008 rate case.[4] I do not agree with the majority that, in these tough economic times, the Company should be allowed to increase the number of employees. I do agree, however, with the Consumer Advocate that the maximum number of employees should be 107.[5] My conclusion is based upon the current 108 employee count[6] and the exclusion of the government affairs specialist, who is a registered lobbyist in the state.[7] Lobbying is not necessary for the provision of water service and, therefore, expenses relating to lobbying should not be funded by consumers of the Company and should be excluded for ratemaking purposes. In my opinion, the lobbyist is doing the bidding of the stockholders, and I cannot in good conscience conclude that any portion of this expense is appropriate for the ratepayers to bear.[8] My conclusion is also consistent with agency precedent to exclude those expenses. Therefore, I would reduce the revenue increase adopted by the majority by $163,944.

I believe that the finance manager recently hired by TAWC[9] duplicates a portion of American Water Works Service Company's function for finance services that are provided to TAWC. It was appropriate when there was no finance manager at the Company to pay the management fees to the Service Company to cover that service. However, now that a local finance manager has been hired at the Company, I believe there is a duplication of services by the Company and the Service Company. The

[8] The majority excluded 20% of the expenses for the lobbyist.

[9] Transcript of Proceedings, v. III-A, pp 54-56 (March 2, 2011).

Company failed to convince me that the newly hired finance manager would be doing different or new duties than what the Service Company had been doing. A prudency test would not allow the double paying for the same services. In the test year that the Authority selected, there is $573,170 allocated to the Finance services category that the Service Company provides to TAWC. I would eliminate from these management fees the cost for the finance manager of $120,333, including salary and benefits, so that customers would not have to bear the burden of paying for such duplication.

In TRA Docket No. 08-00039, TAWC provided a capital additions forecast that it intended to fund and implement during the attrition period. Funding for these additions was included by the Authority in forecasting the attrition period rate base on which rates in the 08-00039 case were established.[10] The Company, however, did not follow through on its commitment by failing to implement its scheduled capital projects, namely the Citico Treatment Plant project.[11] The net effect was that the Company was granted revenues for needed projects but diverted revenues to other purposes such as dividends and management fees to its service company. In this case, the Company again requests inclusion of the Citico project in its forecasted capital additions in calculating its attrition period rate base.

To assure that capital additions, specifically the Citico treatment plant project, will be implemented and in a timely manner, I would remove the capital additions for the Citico treatment plant project of $5,301,305 from rate base calculations. Based upon my

[10] The Authority adopted the Consumer Advocate's attrition year Construction Work in Progress amount of $5,284,789, which included Citico Phase I. *See In re: Petition of Tennessee American Water Company to Change and Increase Certain Rates and Charges so as to Permit It to Earn a Fair and Adequate Rate of Return on Its Property Used and Useful in Furnishing Water Services to Its Employees,* Docket No. 08-00039, *Order*, p. 38 (January 13, 2009)

[11] The Company states it has completed Phase "IA", but not Phase "IB" of the Citico project. *See* Transcript of Proceedings, v. I-B, pp. 122-124 (February 28, 2011).

calculations, this adjustment will reduce the overall revenue requirement by $753,736. This amount includes the reduced depreciation expense, accumulated depreciation, and the resulting tax effects, but does not include any adjustments to the accumulated deferred income taxes. I would, in essence, establish a tracker so that the company would be allowed rate recovery for this project as it is implemented. This action would assure that rates allowed by the Authority and funded by ratepayers for the needed improvements at the Citico plant would actually go for their intended purposes. Using the "trust but verify" standard, in order to receive recovery, I would require the Company to first submit documentation of its capital additions, not to exceed the projected cost of $5.3 million related to the Citico project, including all associated depreciation and tax effects to the Authority in this docket.

I further conclude that the return on equity should be set at 9.65%. This figure is slightly higher than the Consumer Advocate witness Dr. Klein's maximum recommendation of 9.6% but below the Company's requested 11.5% equity return.[12] This figure is similar to recent equity returns awarded by other state regulatory commissions, especially the 9.75% equity return recently awarded to Kentucky American Water Company by the Kentucky Public Service Commission.[13] Given these factors, I believe that a 9.65% equity return is just and reasonable and is sufficient for the Company to attract the necessary capital. Using the other elements of cost of capital adopted by the majority, this leads to a 7.68% overall rate of return which I also find to be just and reasonable during these economic times. The result of the adoption of this rate of return is to reduce the revenue increase approved by the majority by $282,961.

---

[12] Transcript of Proceedings, v. VI-C, p. 252 (March 7, 2011); Michael A. Miller, Pre-filed Direct Testimony, p. 23 (September 23, 2010).
[13] Michael A. Miller, Pre-filed Rebuttal Testimony, Rebuttal Exhibit MAM 5 (February 8, 2011).

For the foregoing reasons, I respectfully dissent from the majority's decisions and find that TAWC should be granted a revenue increase of $4,242,134 or an increase of 11.28%.

I concur in the approval of the rate design for industrial customers as set forth in the *Summary of Settlement Between CRMA and TAWC* filed by the Chattanooga Regional Manufacturers Association ("CRMA") and the Company on March 28, 2011.[14]

I also concur in the recovery of $275,000 in rate case expenses from TRA Docket No. 08-00039, as ordered by the Court of Appeals, through a separate line-item charge on customers' bills that will discontinue once the full amount is recovered. The amount is to be recovered over a period of six months and from all customer classes.[15] I believe that it is important to note that the Court of Appeals in its Opinion did not prohibit the Authority in future cases from thoroughly reviewing rate case expenses and, using a prudency test, denying or cutting those expenses. Rather, the Court only concluded that we needed to explain the reasons for any denial or cuts more fully in the record or in our orders.[16]

Eddie Roberson 9-30-11

Eddie Roberson, Director Date

[14] At the regularly scheduled Authority Conference held on April 18, 2011, I concurred with Chairman Freeman's motion to approve the settlement agreement between CRMA and TAWC, while Director Kyle voted against the motion.

[15] At the regularly scheduled Authority Conference held on August 22, 2011, I concurred with Chairman Freeman's motion to recover the rate case expenses from Docket No. 08-00039, as mandated by the Court of Appeals, through a separate line-item charge on customers' bills, while Director Kyle voted against the motion.

PETITIONER'S EXHIBIT KAH
PAGE 1 OF 31
IURC CAUSE NO. 43187

DIRECT TESTIMONY
OF
KERRY A. HEID

I. INTRODUCTION AND OVERVIEW

1. Please state your name and business address.

A. My name is Kerry A. Heid. My address is 3212 Brookfield Drive, Newburgh, IN 47630.

2. What is your occupation?

A. I am an independent rate consultant. I have been engaged by Indiana-American Water Company ("Petitioner") to recommend and develop a fuel and purchased power cost recovery mechanism, hereinafter referred to as a Purchased Power Adjustment ("PPA"), in this proceeding.

3. What is your educational background?

A. In 1973 I graduated from Purdue University with a Bachelor of Science degree in Civil Engineering. In 1985 I graduated from Indiana University with a Master of Business Administration degree, majoring in Finance.

4. Do you hold any professional accreditations?

A. Yes. I have been a registered Professional Engineer in the State of Indiana since 1977.

5. Please describe your business experience.

A. My business experience and qualifications are set forth in Petitioner's Exhibit KAH-1. I was formerly Director of Rates for Vectren Corporation, a combination electric and gas electric utility. I would also note that I am a member of the American Water Works Association ("AWWA") Rates and Charges Committee, which is responsible for the AWWA Water Rates Manual M1, "Principles of Water Rates, Fees, and Charges." I am also on the AWWA Rates and Charges Subcommittee that is drafting the next edition of the AWWA Water Rates Manual. I was also formerly Principal Water and Sewer Engineer with the Indiana Utility Regulatory Commission (and its predecessor the Public Service Commission of Indiana), as well as a member of the NARUC (National Association of Regulatory Utility Commissioners) Water Subcommittee.

6. Have you previously testified before this Commission?

A. Yes. I have testified on numerous occasions before this Commission.

7. Please discuss how your testimony is organized.

A. My testimony is organized into the following sections:

I. Introduction and Overview

II. Nature of Fuel and Purchased Power Costs

III. Impact of Nature of Costs on Ratemaking Methodologies

IV. Purchased Power Adjustment Mechanism

8. What exhibits are you sponsoring in this proceeding?

A. I am sponsoring the following exhibits:

KAH-1	Business Experience and Qualifications of Kerry A. Heid.
KAH-2	Listing of Petitioner's Electric Suppliers and Tariffs
KAH-3	Listing of Electric Suppliers' Rate Adjustment Mechanisms
KAH-4	Hoosier Energy Wholesale Power Cost Tracker
KAH-5	Proposed PPA Tariff Sheets
KAH-6	Proposed PPA Schedules
KAH-7	PPA Filing and Reconciliation Time Line

9. What is the purpose of your testimony concerning Petitioner's proposed PPA?

A. The purpose of my testimony concerning the PPA is to discuss the proposed method for the recovery of fuel and purchased power costs, as well as the policy, ratemaking, financial and accounting aspects of Petitioner's request for authority to recover the purchased power costs through this mechanism.

My testimony presents Petitioner's proposal for the recovery of fuel and purchased power costs. That proposal is for the implementation of a PPA tracker mechanism utilizing actual fuel and purchased power costs for an historical twelve (12) month period. These amounts would be recovered over a subsequent 12-month period and would be subject to an annual

reconciliation of actual costs to recovered costs.

10. Please briefly summarize why Petitioner is proposing a PPA.

A. Fuel (primarily natural gas) and purchased power costs are the single largest operation and maintenance expense for Petitioner. The natural gas and electric utility industries have been in the midst of unprecedented change. The Commission is well aware of the volatility in the natural gas market and its impact on customers. Increasingly complex and costly federal environmental regulations and the increasing price of fuel are causing recurrent cost increases to purchased power. Moreover, costs from the electric utilities' participation, either directly or indirectly via their wholesale suppliers, in Regional Transmission Organizations (principally the Midwest Independent System Operator, or "MISO") are being passed through to customers through the Fuel Adjustment Clauses ("FAC") on a quarterly basis or through MISO trackers on a quarterly basis. The ever-changing nature of fuel (natural gas) and purchased power costs does not fit within the traditional test year ratemaking framework that requires pro forma rate case adjustments to be fixed, known and measurable and occurring within twelve (12) months following the end of the test year. The timely recovery of costs is reasonable from a ratemaking perspective, in that a basic tenet of regulation is that the utility should have a reasonable opportunity to recover its prudently-incurred costs of providing service.

II. NATURE OF FUEL AND PURCHASED POWER COSTS

11. Please discuss Petitioner's fuel costs.

A. Petitioner's fuel costs are primarily natural gas costs used for domestic service to its various district offices. As such, it is a relatively small percentage of the total fuel and purchased costs. However, as the Commission is only too well aware, the volatility of the natural gas marketplace and the ability of some gas utilities to change their Gas Cost Adjustments ("GCAs") as often as monthly places a burden on customers, including Petitioner who must incur these costs to provide service to its customers.

12. Please describe the Petitioner's purchased power costs.

A. Petitioner is served by 17 different electric utilities under 51 different electric rate schedules. These electric utilities and their associated tariff rate schedules are identified on Petitioner's Exhibit KAH-2. Petitioner is served by all five investor-owned utilities (IOU's) operating in Indiana, as well as four municipal utilities and eight electric distribution cooperatives. The Indiana Municipal Power Agency ("IMPA") sells power to all four of the municipal utilities. Of the four municipal utilities, three remain regulated by the Commission. All eight electric distribution cooperatives purchase power from either Hoosier Energy Rural Electric Cooperative ("Hoosier Energy") or Wabash Valley Power Association ("WVPA"). Of the eight electric distribution cooperatives, only two remain regulated by the Commission.

PSI Energy (PSI), Southern Indiana Gas & Electric Company (Vectren), Northern Indiana Public Service Company (NIPSCO) and Indianapolis Power & Light Company (IPL) are all members of MISO, as are IMPA, Hoosier Energy and WVPA.

13. Please describe the changes occurring in the electric utility industry that give rise to the electric price volatility that the proposed PPA addresses.

A. The electric utility industry has been in the midst of unprecedented change during the past few years, and the transition seems to be far from over. One only need review the Commission's annual Electric Reports to the Regulatory Flexibility Committee of the Indiana General Assembly ("Regulatory Flexibility Report") to obtain a sense of the changes. The Executive Summary of the 2006 Regulatory Flexibility Report summarizes the issues facing customers:

> Increasingly complex and costly federal environmental regulations and the increasing price of fuel are the primary factors causing increases in the cost of electricity. The recovery of costs associated with increased coal and natural gas prices as well as the costs associated with the installation of new pollution control equipment have resulted in recurrent cost recovery proceedings before the Commission. Customers will also realize some costs from their power supplier's participation in Regional Transmission Organizations ("RTOs"—the Midwest ISO in Carmel or the PJM Interconnection).

<u>Environmental</u>

14. The above quote references increasingly complex and costly environmental regulations as causing increases in the cost of electricity. Please explain.

A. Each electric generating utility must comply with applicable federal and state legal requirements, including environmental rules promulgated by both the United States Environmental Protection Agency ("USEPA") and by the Indiana Department of Environmental Management ("IDEM"). Such rules establish environmental compliance standards that govern emissions from electric generating units. Electric generating units have been subject to increasingly more stringent pollution reduction requirements since the 1990 amendments to the Clean Air Act.

15. Please describe some of the pollution reduction requirements currently facing the electric utilities.

A. Under the Clean Air Act, each state is required to adopt a State Implementation Plan ("SIP") to implement the attainment and maintenance of National Ambient Air Quality Standards ("NAAQS") for a number of pollutants. If the USEPA makes a finding that a SIP is substantially inadequate to achieve the attainment or maintenance of the NAAQS in a state, the USEPA may call upon the state to revise its SIP ("a SIP Call").

In 1998, the USEPA issued a NO_x SIP Call that required many states, including Indiana, to develop revised SIPs designed to reduce NO_x emissions to meet budgeted levels the USEPA had set for each state. Indiana was required to propose a SIP by October 2000 that would implement controls on emissions sufficient to meet the USEPA's NO_x budget

by May 2004. In order to meet the Indiana NO_x budget prescribed by the USEPA, Indiana's SIP Call required certain utility NO_x controls that would limit the acceptable level of emissions from electric generation.

In January 2004, the USEPA published two new significant proposed emission reduction requirements: (1) the Clean Air Interstate Rule ("CAIR"); and (2) the Clean Air Mercury Rule ("CAMR"). According to the USEPA, these two rules, which are separate but closely related, will trigger the largest investment in air quality improvement in the history of the United States. The new CAIR and CAMR rules will require Indiana's electric generating utilities to achieve reductions in SO_2, NO_x and mercury emissions that are in addition to the previous SO_2 and NO_x reductions.

16. What are the immediate implications of the required pollution reduction requirements?

A. Indiana electric utilities have begun to plan and prepare their systems for compliance with the environmental mandates. IPL, PSI, NIPSCO and Vectren have received approval from the Commission of their individual compliance plans. Moreover, each of these utilities has received approvals from the Commission to implement environmental cost adjustments that allow them to immediately pass through the capital and operating costs to customers as frequently as semi-annually.

17. Please elaborate.

A. These environmental compliance plans and associated cost recovery are addressed in various Indiana statutes: Indiana Code §§8-1-8.8 directs the Commission to encourage clean coal projects through the application of financial incentives and timely recovery of costs associated with such projects; and Indiana Code §§8-1-2-6.6 and 6.7 discuss ratemaking treatment for Clean Coal Technology ("CCT"). These statutes generally serve to encourage the use of Illinois Basin coal through the installation of CCT equipment by allowing the utilities to recover their operation and maintenance expenses, depreciation, taxes and capital costs through retail rate mechanisms.

Cost of Fuel

18. The Commission's 2006 Regulatory Flexibility Report also noted that the increasing price of fuel is another primary factor causing increases in the cost of electricity. Please explain.

A. The Commission's 2006 Regulatory Flexibility Report notes that the recovery of increased costs associated with coal and natural gas have also resulted in recurrent cost increases through the quarterly FAC Proceedings. The volatility and extreme price levels in the natural gas marketplace have been well documented, and the Commission is well aware of these impacts on customers.

The Indiana electric industry has long relied on coal as its major source for generating electric power in Indiana. Coal's local abundance and low cost have made it the local choice for most Indiana base load generation. However, the price of coal has recently experienced increases as well. For example, the Energy Information Administration ("EIA") Annual Coal Report issued in October 2006 noted:

> The majority of coal deliveries to the electric power sector are through long-term contracts, sometimes in conjunction with spot purchases to supplement demand. Average delivered coal prices at electric utilities (a subset of the electric power sector) increased for a fifth consecutive year to $31.22 per short ton, an increase of 14.4 percent.

In addition, it is not uncommon for coal contracts to have escalation clauses based on diesel fuel prices.

Finally, the additional fuel costs attributable to MISO operations are now being passed through to customers in the FACs. MISO now directs the dispatch of all of the MISO members' generating units on a regional economic dispatch basis considering the economics of the generation offers into the MISO market. This has created a number of new fuel-related charges or credits that can be incurred or received by the MISO members. In its Order in Cause No. 42685, dated June 1, 2005, the Commission determined that many of these charges and credits represented components of the cost of fuel and are thus subject to recovery through the fuel adjustment clause ("FAC"). This will be discussed in more detail in the next section of my testimony.

Midwest Independent System Operator

19. The Commission's 2006 Regulatory Flexibility Report also notes that customers will also realize some costs from their electric utility's participation in Regional Transmission organizations, e.g. MISO. Please explain.

A. Transmission policy in the United States has been in a constant state of change since the enactment of the Energy Policy Act of 1992, which initiated electric utility industry reform. In 1996, the Federal Energy Regulatory Commission ("FERC") implemented open access transmission through FERC's Orders 888 and 889, which provided for nondiscriminatory transmission access. Those two Orders marked the beginning of a dramatic change to the way in which electric transmission systems are used. To further FERC's open access initiative, FERC implemented Order 2000 in December 1999, which defined the requirements of Regional Transmission Organizations ("RTOs"), and strongly encouraged transmission owners to join an RTO. As a result of these industry initiatives, the cost structure of an electric utility's service function was fundamentally altered.

20. What RTOs have been formed in Indiana?

A. Two RTOs serve utilities in Indiana – MISO and PJM. Most Indiana electric utilities are members of MISO, including PSI, NIPSCO, IPL, Vectren, IMPA, WVPA and Hoosier Energy. Only Indiana & Michigan Power Company

("AEP") is a member of PJM. Consequently, the RTO having the greatest potential impact on Petitioner is MISO, and thus the subsequent discussions on RTOs will be focused on MISO.

21. Please describe the MISO-related costs incurred by the electric utilities.

A. Not only are there new administrative costs associated with managing MISO's transmission support operations and its energy market platform, but there are also newly required capital investments related to constructing new transmission capacity needed to support the increased power flows associated with the Midwest Energy Market. Electric utilities' MISO-related costs can be grouped into the following three categories: (1) non-fuel charges assessed by MISO pursuant to rate schedules that have been approved by the FERC; (2) fuel costs related to the participation in the Day 2 Energy Market; and (3) transmission costs included in MISO's FERC-approved Attachment O formula rate for the electric utilities. As further discussed below, the fuel costs will flow through the quarterly FAC. The remaining two types of non-fuel costs may be subject to recovery through dedicated trackers or subsequent base rate cases.

A. NON-FUEL CHARGES ASSESSED BY MISO

22. What are the non-fuel charges assessed by MISO?

A. MISO currently assesses the following non-fuel charges to electric utilities:

(1) **Schedule 10 and Schedule 10-FERC–ISO Cost Recovery Adder and FERC Annual Charges Recovery.** These schedules provide for the

recovery by MISO of the cost of building and operating MISO's control center, coordinated regional transmission planning, administering the MISO tariff, any deferred pre-operating costs and recovery of the annual assessments paid to the FERC by MISO.

(2) **Schedule 16–Financial Transmission Rights Administrative Service Cost Recovery Adder.** This schedule provides for the recovery of Day 2 Market costs related to bilateral trading coordination, FTR administration, FTR software tools, simultaneous feasibility analysis, revenue distribution, and FTR administration.

(3) **Schedule 17–Energy Market Support Cost Recovery Adder.** This schedule provides for the recovery of Day 2 Market costs related to market modeling and scheduling, market bidding, locational marginal pricing coordination, market settlements and billing, market monitoring functions, and the economic dispatch of generating resources to serve load in the MISO footprint while establishing a spot energy market.

(4) **Schedule 24–Control Area Operator Cost Recovery.** This schedule provides for the recovery of control area or "balancing authority" costs incurred by transmission owing members of MISO as a result of implementing the Day 2 Market.

23. Are there other non-fuel charges that the electric utilities will incur under the MISO tariff?

A. Yes. The Commission found some MISO charges to be non-fuel related in Cause No. 42685. In addition, electric utilities will be assessed charges by MISO for reliability upgrades to the MISO transmission system. At some later date, the electric utilities will also be assessed charges for economic upgrades to the MISO transmission system that are built by other transmission owning members of MISO. Finally, at some point in the future, the electric utilities could also be assessed charges for reactive power service provided by generators in the utilities' control areas.

B. FUEL COSTS ASSOCIATED WITH THE MISO DAY 2 ENERGY MARKET

24. Please describe the fuel costs related to the Day 2 Energy Market.

A. Under the Day 2 Energy Market platform, MISO directs the dispatch of all of the MISO members' generating units on a regional economic dispatch basis considering the economics of the generation offers into the MISO market. The following fuel-related charges or credits can be incurred or received by the MISO members: (a) financial transmission rights ("FTR") congestion costs; (b) FTR congestion credits; (c) FTR auction settlements; (d) Virtual Bids and Offers in the Day-Ahead Market used for hedging jurisdictional load; (e) Day-Ahead recovery of Unit Commitment Costs; (f) Excess Congestions Charge Fund Credits; (h) resource adequacy commitment ("RAC") Recovery of Unit Commitment Costs; (i) Marginal Losses Surplus Credit; (j) Inadvertent Energy Charges or Credits; and (k) Revenue from Uninstructed Deviation Penalties. In its Order in Cause No. 42685, dated June 1, 2005, the Commission determined that these items represented components of the cost of fuel and are thus subject to recovery through the FAC.

C. TRANSMISSION COSTS INCLUDED IN MISO'S ATTACHMENT O FORMULA RATE

25. Please describe MISO Attachment O.

A. MISO Attachment O is used to determine the transmission service rates under the MISO tariff for loads that sink in members' control areas.

Attachment O, which is updated annually, is used to determine the annual transmission revenue requirements for each transmission owner in MISO. For an investor owned utility, revenue requirements are determined based on plant and expense data from the utility's FERC Form 1 and include the following components: (a) operating expenses, including operation and maintenance expenses, taxes other than income tax, and depreciation expenses; (b) return on transmission net investment grossed up for income taxes; and less (c) transmission revenue credits.

26. Has the Commission allowed any utilities in Indiana to recover these costs through a MISO tracker?

A. Yes. First, as already discussed, the Commission has previously determined that a certain group of MISO-related costs are fuel costs and, as such, can be recovered through the quarterly FAC.

Second, in its Order in PSI's general rate case, Cause No. 42539 approved May 18, 2004, the Commission permitted PSI to quarterly track these non-fuel MISO charges through Standard Contract Rider No. 68-MISO Management Cost and Revenue Adjustment. In approving PSI's adjustment rider, the Commission stated:

> We find reasonable PSI's proposal to track Midwest ISO related costs and revenues, including costs that are: (1) the results of decisions by the FERC; (2) variable in amount from year to year; (3) variable as to timing; (4) substantial in individual and aggregate amounts; and (5) outside the control of PSI. PSI's proposal is balanced and designed to flow through to customers Midwest ISO-related transmission revenues received by PSI. Therefore, we find that PSI's proposal to track Midwest ISO related costs should be

approved. (Cause No. 42539, Order dated May 18, 2004, at p. 120).

27. Have other utilities proposed MISO trackers?

A. Yes. In its current electric rate case, Cause No. 43111, Vectren is proposing a MISO Cost and Revenue Adjustment ("MCRA") to recover incremental changes in the costs associated with its membership in MISO. Vectren's proposed MCRA would allow for the timely recovery of incremental MISO charges and incremental MISO transmission costs. Specifically, Vectren is proposing to recover, on a quarterly basis, incremental changes in the non-fuel related charges assessed by MISO and incremental charges in the key cost and revenue components of Vectren's transmission revenue requirements determined through the application of the FERC-approved Attachment O calculations.

28. Are the aforementioned environmental, fuel and MISO costs the only sources of purchased power cost volatility being experienced by Petitioner?

A. No. First, it should be noted that in addition to the aforementioned trackers, the electric utilities have a number of other trackers with which they flow through cost increases and decreases on a periodic basis. Petitioner's Exhibit KAH-3 lists the many rate adjustment mechanisms utilized by the Petitioner's electric suppliers to adjust electric rates as frequently as quarterly.

Second, Vectren has recently filed a general rate case in which it proposes

to increase rates by an average of over 18 percent. In its filing, it also indicates that over the next five years, it expects to invest at least an additional $775 million in capital investments. It also indicated that it is "on the brink of our next investment in baseload generation," a coal fired unit with the latest emissions control technology.

Moreover, it should be noted that of the 17 different power suppliers, seven are no longer regulated by this Commission and, as such, can raise their rates with only the adoption of an ordinance or resolution.

29. Please summarize your testimony to this point.

A. My preceding testimony has described the various environmental, fuel and structural (e.g. MISO) issues, as well as other trackers and general rate cases, that are causing the recurrent cost changes to fuel and purchased power costs for Petitioner.

In the case of generating utilities, the utilities are seeking FAC changes, environmental trackers and MISO trackers, and base rate increases. In the case of IOUs, those costs flow directly through to the retail customer on a real-time basis. In the case of IMPA, Hoosier and WVPA, these costs are passed through to their member companies, *i.e.* the municipal electric utilities and rural electric cooperatives who provide the electric service to Petitioner, who in turn, pass these cost increases immediately on to the end use customers like Petitioner through wholesale power cost trackers.

Petitioner's Exhibit KAH-4 is an excerpt from Hoosier Energy's webpage that

discusses the need for a wholesale power cost tracker to track unpredictable costs that a utility incurs in providing service to customers.

30. What is the impact on Petitioner of this ability of the utilities to track through these cost increases on a real-time basis?

A. The result is that Petitioner will receive frequent rate changes from its electric utility providers that it will not be able to reflect in its rates under traditional ratemaking. The traditional ratemaking approach in Indiana specifies that an historical test year is used, and that pro forma adjustments can be made to operating expenses if those adjustments are fixed, known and measurable and occurring within twelve (12) months following the end of the test year. With the number of different suppliers, Petitioner experiences natural gas and electric cost changes constantly. These cost changes are very real, but would not be considered fixed, known and measurable for traditional ratemaking treatment. Moreover, these costs may not yet be known at the time of the utility's filing of its case-in-chief. Therefore, most purchased power cost changes could not be reflected as pro forma adjustments in a rate case. Moreover, these pro forma adjustments are only allowed twelve (12) months beyond the end of the test year, so a utility filing rate cases even every two or three years has no opportunity to recover the majority of these costs. This violates a basic tenet of regulation in that the utility does not have a reasonable opportunity to recover these prudently-

incurred costs in providing service to its customers.

31. Are these fuel and purchased power costs material to Petitioner?

A. Yes. Fuel and purchased power costs are the single largest operation and maintenance expense to Petitioner. Moreover, fuel and purchased power are also the costs most likely to experience significant changes, as described herein. To illustrate, the following table illustrates the rapid changes in fuel and purchased power expense since 2003.

12 Months Ended	Fuel and Purchased Power
12/31/03	$4,255,028
12/31/04	$4,435,477
12/31/05	$4,852,743
6/30/06 (a)	$5,342,796

(a) Test Year.

It reflects a 25.6 percent increase in just two and one-half years, an annual rate of increase of 9.5 percent. Moreover, this rate of change is poised to only accelerate as a result of the factors previously described.

Fuel and purchased power costs are in excess of 60 percent of the Petitioner's cost of production of water. Moreover, fuel and purchased power costs comprise a material percentage of Indiana-American's net income, historically ranging from 22 percent to 31 percent of net income. Based on actual financial data through September 30, 2006, it is estimated

that fuel and purchased power will comprise 71 percent of net income during 2006. Therefore, accurate cost recovery of fuel and purchased power costs is vitally important to Petitioner.

III. IMPACT OF NATURE OF COSTS ON RATEMAKING METHODOLOGIES

32. Based on your experience with utility regulation and ratemaking, are you familiar with the traditional ratemaking methodologies that have been employed by the Commission as well as other regulatory commissions?

A. Yes.

33. What are those traditional ratemaking methodologies?

A. In general, two traditional ratemaking methodologies are common in Indiana and other regulatory jurisdictions. For the purpose of my testimony, I will refer to these methodologies as the "test year adjusted" base rate approach and the tracker approach.

Under the test year adjusted base rate approach, base rates are set prospectively and are based on an adjusted test year that is presumed to be representative of conditions when rates will be in effect. The test year adjusted base rate approach measures the total costs incurred in conducting

operations over a historical twelve (12) month period, and adjusts those costs for changes that are fixed, known and measurable and occurring within twelve (12) months following the end of the test year. The adjusted costs are intended to be representative of prospective conditions when rates will be in effect, and sets rates that will produce revenues to match costs of that prospective period.

Under the tracker approach, rates are adjusted through a reconciliation or "true-up," mechanism to ensure that an accurate recovery of costs occurs.

34. **What is your understanding of the difficulty in estimating expected fuel and purchased power costs for pro forma adjustment purposes in a rate case?**

A. As previously described, the recovery of costs associated with increased coal and natural gas prices as well as costs associated with the installation of new pollution control equipment and MISO-related costs have resulted in recurrent cost recovery proceedings before the Commission. Moreover, for those utilities not regulated by the Commission, they only need to pass an ordinance or resolution adopting new rates, without any regulatory proceeding. Therefore, unlike earlier years when electric prices were relatively stable, Petitioner is now confronted with ever changing fuel and purchased power costs.

35. In your opinion, for the purpose of accurately recovering purchased power costs, do such characteristics make the use of the test year adjusted ratemaking methodology less desirable than the tracker ratemaking methodology?

A. Yes. If the cost data used to set rates according to the test year adjusted ratemaking methodology does not include the impacts on fuel and purchased power costs from these various electric utility trackers and other increases, the rates approved in this case will not function as intended. Under-recoveries of costs will be the probable outcome.

The ever-changing nature of fuel and purchased power costs does not fit within the traditional test year ratemaking framework that requires pro forma adjustments to be fixed, know and measurable and occurring within twelve (12) months following the end of the test year. Moreover, the fact that the utility attempts to go at least a number of years between general rate cases exacerbates this problem and virtually ensures that Petitioner will under-recover its fuel and purchased power costs.

36. In your opinion, what factors should the Commission consider in evaluating which ratemaking methodology is most appropriate for the recovery of fuel and purchased power costs?

A. In my opinion the test year adjusted base rate approach is <u>not</u> the appropriate means for cost recovery when the following characteristics are present:

- Costs are certain to occur, but future levels are variable from year to year, and accurate projections or pro forma adjustments are not possible;
- Costs are to a great extent beyond the control of the utility;
- Costs are potentially large in relation to net income, making it important to recover them accurately and on a timely basis.
- Cost over-recovery or under-recovery is possible due to the above factors, creating the possibility of a significant detrimental impact on customers or shareholders.

When these characteristics are present, the most accurate, fair and efficient means of matching recoveries with costs is through the use of the tracker ratemaking methodology.

37. Are the above characteristics present with respect to the purchased power costs that are proposed to be subject to the PPA?

A. Yes. My previous testimony indicates that some level of fuel and purchased power changes are certain to occur, while substantial uncertainties exist with respect to the level of those costs. Moreover, fuel and purchased power costs are to a great extent beyond the control of the utility. Finally, purchased power costs are the single largest operation and maintenance expense for Petitioner and constitute a significant percentage of net income.

Given the wide variations in and the difficulties in making estimates of the level of fuel and purchased power costs, combined with the fact that they do not fit into the fixed, known and measurable ratemaking framework, the possibility and indeed the probability exists that the test year adjusted

ratemaking methodology will result in an over-recovery or an under-recovery of those costs. The tracker ratemaking methodology provides the most accurate, fair and efficient means of recovering fuel and purchased power costs. Therefore, Petitioner is proposing a Purchased Power Adjustment mechanism to ensure accurate cost recovery of its fuel and purchased power costs.

IV. PURCHASED POWER ADJUSTMENT MECHANISM

38. Please summarize Petitioner's proposed PPA mechanism.

A. The proposed PPA would have the following features:

(1) An appropriate pro forma test year amount of fuel and purchased power costs would be determined and included within base rates. The PPA, then, would reflect only the incremental increase or decrease in estimated purchased power costs from the amount included in base rates.

(2) The PPA would be based on actual historical fuel and purchased power costs incurred during a previous twelve month period. To provide for prior Commission scrutiny and approval of each PPA, Petitioner would make an annual filing with the Commission that would consist of testimony and other evidence establishing the appropriateness of the purchased power costs incurred, as well as the reconciliation of prior period over and under-recoveries.

(3) A volumetric charge would be determined by dividing the allocated fuel and purchased power costs to be recovered (including previous period over and under-recoveries) by estimated annual sales volumes. Consistent with the concept of single tariff pricing that the Commission has previously approved for Petitioner, a single PPA rate would be determined that would be applicable to all of Petitioner's water systems.

(4) The PPA would be subject to an annual reconciliation in a process similar to the current DSIC reconciliation process. Any resulting over or under-recovery of fuel and purchased power costs (purchased power variances) would be credited/recovered in subsequent PPAs.

39. How will the historical fuel and purchased power costs be determined that would be included in the PPA for recovery in the subsequent PPA recovery period?

A. Fuel and purchased power costs are segregated and recorded in Account 615. Therefore, the historical fuel and purchased power costs recorded in this account during the previous twelve (12) month period would be used.

40. How would Petitioner treat purchased power cost over or under-recoveries due to variations from the estimated volumes?

A. PPA variances will be determined annually in connection with Petitioner's annual PPA proceedings. These variances will be flowed back or recovered over a twelve (12) month period in subsequent PPAs.

41. Please summarize the PPA.

A. The PPA provides for the tracking of fuel and purchased power costs with an annual reconciliation, so that customers will neither underpay nor overpay. If these highly variable fuel and purchased power costs were included in base rates without reconciliation, the recovery would remain at a fixed level until the next rate case, and any variance from actual costs would not be subject to collection or refund. The PPA eliminates this problem.

42. Please describe the document that has been marked as Petitioner's Exhibit KAH-5.

A. Petitioner's Exhibit KAH-5 includes two proposed tariff sheets reflecting the proposed Purchased Power Adjustment. Petitioner's Exhibit KAH-5, Page 1 of 2, is the tariff sheet reflecting the proposed Purchased Power Adjustment rates. Petitioner's Exhibit KAH-5, Page 2 of 2, is the tariff sheet setting forth the Base Rate Fuel and Purchased Power Costs. This tariff sheet will provide the per Ccf (hundred cubic feet) and per Mgal (thousand gallons) fuel and purchased power costs included in base rates necessary for the PPA calculations and reconciliation. The calculation of the Base Rate Purchased Power Costs is included in Petitioner's Exhibit KAH-6, Schedule 2, which will be subsequently discussed.

PPA SCHEDULES

43. Please discuss the PPA ratemaking calculations that Petitioner proposes to submit to the Commission as part of each annual filing.

A. Petitioner's Exhibit KAH-6, consisting of Schedules 1 through 4, reflects the ratemaking calculations that Petitioner proposes to submit to the Commission as part of each annual filing. Hypothetical numbers are reflected on Petitioner's Exhibit KAH-6 since it is merely for illustrative purposes at this time.

44. Please describe Schedule 1 of Petitioner's Exhibit KAH-6.

A. Schedule 1 of Petitioner's Exhibit KAH-6 presents the derivation of the Purchased Power Adjustment rates for the twelve (12) month rate period. Lines 1 through 3 reflect the total fuel and purchased power costs to be recovered during the current PPA period. It is comprised of the historical fuel and purchased power costs (Line 1) and the over- or under-recovery variance from a prior period (Line 2).

Line 4 is the projected Ccf sales, which is divided by the total PPA costs (Line 3) to determine the total PPA unit cost (Line 5).

The Base Rate PPA Unit Cost (Line 6) is deducted from the total PPA Unit Cost (Line 5) to determine the PPA Rate prior to gross-up for Indiana Utility Receipts Tax ("IURT"), which is reflected on Line 7.

Line 8 shows the proposed PPA Rate in $/Ccf (hundred cubic feet), which is derived by dividing the PPA Rate (Line 7) by the IURT gross-up factor of 0.9847. Line 8a converts the proposed PPA Rate from Line 8 into $/Mgal (thousand gallons).

45. Please describe Schedule 2 of Petitioner's Exhibit KAH-6.

A. Schedule 2 of Petitioner's Exhibit KAH-6 presents the calculation of the Base Rate Cost of Fuel and Purchased Power. It is derived by simply dividing the total pro forma fuel and purchased power costs determined in this proceeding by the adjusted test year (pro forma) Ccf sales for the water districts determined in this proceeding.

46. Please describe Schedule 3 of Petitioner's Exhibit KAH-6.

A. Schedule 3 presents the reconciliation of projected costs to actual costs for an historical twelve (12) month period. The resulting over-recoveries or under-recoveries would be flowed back or recovered over the twelve (12) month rate period of that current PPA filing. This reconciliation process is similar to the familiar DSIC reconciliation process. Lines 1 through 3 calculate the "Fuel and Purchased Power Costs Recovered" by multiplying the total actual Ccf sales for the water districts times the billed PPA rate.

Line 4 reflects the "Fuel and Purchased Power Costs to be Recovered" based on the actual Fuel and Purchased Power Expenses incurred during the previous period, plus the over- and under-recovery variances that are to be recovered/flowed back during the period.

Line 5 reflects the calculation of the over- or under-recovery variance, which is calculated by subtracting the "Fuel and Purchased Power Costs Recovered" (Line 3) from the "Fuel and Purchased Power Costs to be Recovered" (Line 4).

TIMING OF PPA FILINGS

47. Please describe Petitioner's Exhibit KAH-7.

A. Petitioner's Exhibit KAH-7 reflects the estimated timeline for the first three PPA filings. The various dates reflected on this schedule are based on the

assumption that the Commission will issue its approval in time to file the first PPA ("PPA-1") by October 1, 2007. If the approval date changes from that assumed in this testimony for illustrative purposes, each date on the timeline would simply be adjusted accordingly.

48. Please describe the timing of the initial Purchased Power Adjustment filing, PPA-1.

A. The historical period for which costs would be recovered in PPA-1 would be the twelve (12) month period from August 2006 through July 2007. This is represented on Petitioner's Exhibit KAH-7 by the blue shaded, vertically striped area. The PPA-1 filing would be submitted on approximately October 1, 2007, with an estimated rate effective date of January 1, 2008. The PPA-1 rates would be in effect from January 2008 through December 2008, as represented by the blue shaded, horizontally striped area. Because this would be the initial filing of the Purchased Power Adjustment, there would be no historical period to reconcile.

49. Please describe the second Purchased Power Adjustment filing, PPA-2.

A. PPA-2 would recover fuel and purchased power costs for the subsequent historical period, i.e. the twelve (12) month period from August 2007 through July 2008. Please refer to the yellow shaded, vertically striped area on Petitioner's Exhibit KAH-7. The PPA-2 filing would be submitted on approximately October 1, 2008, with an estimated rate effective date of

January 1, 2009. The PPA-2 rates would be in effect from January 2009 through December 2009, as represented by the yellow shaded, horizontally striped area. At the time of filing of PPA-2, the PPA-1 rates would not yet have been in effect for a full twelve (12) month period. Therefore, PPA-2 will not reconcile a previous period.

50. Please describe the third Purchased Power Adjustment filing, PPA-3.

A. PPA-3 would recover fuel and purchased power costs for the subsequent historical period i.e. the twelve (12) month period from August 2008 through July 2009. Please refer to the green shaded, vertically striped area on Petitioner's Exhibit KAH-7. The PPA-3 filing would be submitted on approximately October 1, 2009, with an estimated rate effective date of January 1, 2010. The PPA-3 rates would be in effect from January 2010 through December 2010, as represented by the green shaded, horizontally striped area. An entire twelve (12) months of actual historical data from the PPA-1 rates covering January 2008 through December 2008 would now be available to reconcile, and it is represented on Petitioner's Exhibit KAH-7 by the blue shaded, horizontally striped area.

51. Would the subsequent Purchased Power Adjustment filings follow the same pattern as the third PPA filing?

A. Yes. Each projection and reconciliation period will simply roll forward by twelve (12) months.

52. Does this conclude your prepared direct testimony?

A. Yes.

A FINITE-HORIZON DYNAMIC PROGRAMMING APPROACH TO THE TELEPHONE CABLE LAYOUT PROBLEM

Steven F. Maier, James H. Vander Weide and Chun H. Lam
Graduate School of Business Administration
Duke University
Durham, North Carolina

Abstract

The well-known "capacity expansion" or "plant size" problem in capital theory involves an economic tradeoff between the economies of scale associated with a policy of large, infrequent capacity expansions and the interest savings associated with a policy at the opposite extreme. The problem of determining the optimal size, number and time-phasing of telephone feeder cables involves this same economic tradeoff. An additional complication, however, is the practical restriction that telephone cable comes in only a small number of sizes, i.e., telephone capacity cannot be varied continuously. The latter complication cannot be handled by currently existing algorithms for the "capacity expansion" problem. In this paper we solve the feeder cable expansion problem using a two-stage programming procedure which efficiently decomposes the original formulation into a simple inventory problem and a knapsack problem, both of which can be solved by dynamic programming.

Introduction

A sizeable portion of annual telephone company expenditures are associated with the purchase, installation and maintenance of telephone feeder cables. Since total annual costs are sensitive to the firm's choice regarding the size and time-phasing of cables, substantial savings can often be realized from a careful analysis of the economic tradeoffs characterizing these decisions. In this paper, we present a mathematical model of the Feeder Cable Expansion Problem which can be used to determine the optimal number and size of cables to install in each time period within the firm's planning horizon.[1]

The Feeder Cable Expansion Problem is a member of a well-known class of problems considered previously in the management science/operations research literature. Several examples of this class of problems are (i) determination of economic lot size, (ii) multicommodity warehousing decisions, (iii) labor force planning and (iv) optimal investment in plant capacity for one or more producing areas. (Veinott and Wagner [6] provide an excellent discussion of the mathematical equivalence of these applications. Other references in this interesting area are [2], [3], [4], [5] and [7].) Like the other members of this class of problems, the Feeder Cable Expansion Problem involves a fundamental economic tradeoff between the economies of scale associated with large, infrequent capacity expansions and the low investment opportunity costs (i.e., interest costs) associated with a policy of more frequent, but smaller expansions. Complicating the analysis of the latter problem, however, is the restriction that telephone feeder cable comes in only a small number of sizes. Because of this restriction, the problem is solved using a two-stage programming procedure, which efficiently decomposes the model into a simple inventory problem and a knapsack problem, both of which can be solved by dynamic programming.

Problem Formulation

Consider the Feeder Cable Expansion Problem confronting the telephone company along one segment of a particular cable feed area. Suppose that the company has already chosen the appropriate category and gauge type to employ in this segment, and that it now wants to determine the number of cables, x_{tr}, of size $r = 1,\ldots,R$ to install in each time period t within its planning horizon, $[0,T]$. Furthermore, assume that the company's objective is to minimize the present value of variable costs, $\sum_{t=1}^{T}\sum_{r=1}^{R} \frac{c_r}{(1+i)^t} \cdot x_{tr}$, plus the present value of fixed costs, $\sum_{t=1}^{T} \frac{b}{(1+i)^t} \cdot z_t$, associated with the cable installation plan and that the number of line pairs available in each period must be sufficient to satisfy the demand requirement, d_t, in that period. Each period's demand requirement can be satisfied from an inventory of excess line pairs, s_{t-1}, as well as from newly installed cables. With these assumptions, the telephone company's decision problem can be formulated mathematically as Problem I:

$$\text{Minimize } TC = \sum_{t=1}^{T}\sum_{r=1}^{R} \frac{c_r}{(1+i)^t} \cdot x_{tr} + \sum_{t=1}^{T} \frac{b}{(1+i)^t} \cdot z_t$$

with respect to x_{tr}, s_t, z_t

$$\text{subject to } \sum_{r=1}^{R} \ell_r \cdot x_{tr} + s_{t-1} - s_t = d_t \qquad t=1,\ldots,T$$

$$\sum_{r=1}^{R} x_{tr} \leq M z_t \qquad t=1,\ldots,T$$

$$x_{tr} = 0,1,2,\ldots \qquad t=1,\ldots,T;\ r=1,\ldots,R$$

$$z_t = 0 \text{ or } 1 \qquad t=1,\ldots,T$$

$$s_t \geq 0 \qquad t=1,\ldots,T$$

$$s_o \text{ given,}$$

where

x_{tr} ≡ the number of cables of size r to

be installed in period t,

c_r ≡ the variable cost per foot of installing one cable of size r, assumed for convenience to be independent of t,

i ≡ the discount factor, also assumed for convenience to be constant,

b ≡ the fixed cost of installing cables,

z_t ≡ 1 if any cables are installed in period t, 0 otherwise,

ℓ_r ≡ the number of line pairs in one cable of size r,

s_t ≡ the number of line pairs of excess cable capacity available in period t,

s_o ≡ inventory of excess line pairs above current demand at the start of the planning period,

d_t ≡ the number of lines required in period t,

M ≡ a very large number.

Thus, the Feeder Cable Expansion Problem is technically an integer programming problem containing RT + 2T integer variables. In practice, there may be as many as 13 cable sizes available and a time horizon of 10 or more years. This yields an integer programming problem with at least 150 integer variables. Since a problem of this size is near the computational limits of most commercial integer programming code, an alternative two-stage optimization algorithm is proposed in the next section. This algorithm efficiently finds the global optimal integer solution.

A Two-Stage Solution Procedure

The solution procedure proposed in this section is a two-stage dynamic programming approach. The method is based on the observation that if it were not for the rather complex cost structure of Problem I, the underlying decision problem would be a fairly simple inventory model. In order that this will be clear to the reader, we shall rewrite Problem I in a notationally simpler form. If we let

$$y_t \equiv \sum_{r=1}^{R} \ell_r \cdot x_{tr},$$

then y_t can be interpreted as the number of line pairs that are installed in period t when x_{tr} cables are laid. The present value of the minimum cost of installing these y_t line pairs can then be thought of as a function, $C_t(y_t)$. The determination of these cost functions $C_t(y_t)$ will comprise the first step of the solution procedure and will be described shortly. Assuming that the functions $C_t(y_t)$ have been determined, we can rewrite Problem I as

Problem II:

$$\text{Minimize TC} = \sum_{t=1}^{T} C_t(y_t)$$

$$\text{with respect to } y_1,\ldots,y_T$$

$$\text{subject to } y_t + s_{t-1} - s_t = d_t \quad t=1,\ldots,T$$

$$y_t \text{ and } s_t \text{ nonnegative and integer} \quad t=1,\ldots,T$$

$$s_o \text{ given.}$$

Problem II is equivalent to Problem I. Furthermore, Problem II can be identified as a simple inventory problem. (See for example [1], p. 261.) Like many inventory problems, Problem II can be solved efficiently by means of a dynamic programming recursion. Before discussing the solution of Problem II, it seems appropriate to indicate precisely how the cost functions $C_t(y_t)$ can be determined.

Since $C_t(y_t)$ represents the present value of the minimum cost of installing y_t line pairs in period t, it can be expressed mathematically as:

$$C_t(y_t) = \text{Minimum } \left(\sum_{r=1}^{R} \frac{c_r}{(1+i)^t} \cdot x_{tr} + \frac{b}{(1+i)^t} \right)$$

$$\text{with respect to: } x_{t1},\ldots,x_{tR}$$

$$\text{subject to } \sum_{r=1}^{R} \ell_r \cdot x_{tr} = y_t$$

$$x_{tr} = 0,1,2\ldots \quad \text{for } r=1,\ldots,R$$

where $y_t > 0$ is a parameter.

If one observes that the dependence of this problem on the specific time period t is only in the discount factor $(1+i)^t$, it is possible to write the problem independent of t as

Problem III:

$$C(y) = \text{Minimum } \left(\sum_{r=1}^{R} c_r \cdot x_r \right)$$

$$\text{with respect to: } x_1,\ldots,x_R$$

$$\text{subject to } \sum_{r=1}^{R} \ell_r \cdot x_r = y$$

$$x_r = 0,1,2,\ldots \quad \text{for } r=1,\ldots,R$$

where the solution to Problem III can be used to find $C_t(y_t)$ by the transformation:

$$C_t(y_t) \equiv \frac{C(y_t)}{(1+i)^t} + \frac{b}{(1+i)^t} \quad \text{for } y_t > 0 \qquad (1)$$

$$C_t(0) \equiv 0.$$

Since Problem III must be solved for a great many values of y, this is a parametric integer programming problem. Fortunately, this problem has the form of the familiar knapsack or distribution-of-effort problem (see [1], p. 332) and can be solved in this case by an efficient dynamic programming recursion. Other solutions techniques may also be appropriate. (see for instance [2].)

In an attempt to reduce the number of states in the dynamic programming formulation, we will find it convenient to introduce a scale factor e. We will assume that ℓ_r, for all cable sizes r; d_t, for all time periods t; and s_o are each exactly divisible by e. (Such a factor e always exists, just take e=1.) In order to limit the number of states, we shall choose e as large as possible.

Define

$f_r(y)$ = the cost of the optimal cable layout scheme when the demand equals y and only cable sizes 1,2,...,r are used to satisfy the demand,

$h_r(y)$ = the number of cables of size r used to realize the cost $f_r(y)$.

The dynamic programming recursion can then be written as

$$f_r(y) = \underset{x_r}{\text{minimum}} \{c_r \cdot x_r + f_{r-1}(y-\ell_r \cdot x_r)\} \quad (2)$$

$$f_o(0) = 0 \quad (3)$$

$$f_o(y) = M \quad \text{for } y > 0 \quad (4)$$

where $y = 0, 2e, \ldots, d_1+d_2+\ldots+d_T$, M is a very large number, and the minimization is over $x_r = 0, e, 2e, \ldots, [y/\ell_r]$.

It is important to emphasize again that by solving the dynamic programming formulation for $y=0,e,2e,\ldots,d_1+\ldots+d_T$ one does obtain the entire set of cost curves $C_t(y_t)$, since $C(y) = f_R(y)$ and relation (1) yields $C_t(y_t)$. Furthermore, one obtains all these cost curves by solving only one dynamic program with R stages and $(d_1+d_2+\ldots+d_T)/e$ states. On test data provided by General Telephone and Electronics of the Southeast, solutions were obtained to this problem in less than 15 seconds CPU time on an IBM 370/165 with R=10 and the number of states = 800. Having completed our calculation of the cost curves $C_t(y_t)$ we now consider the solution of Problem II itself.

As mentioned previously, Problem II is in the form of a simple inventory problem, and can be solved by means of a dynamic programming recursion. Define

$g_t(s)$ = the minimum policy cost when s lines of excess capacity are available from the preceding period and there are T - t periods to go.

$y_t(s)$ = the installation level yielding $g_t(s)$.

The dynamic programming recursion can then be written as

$$g_t(s) = \text{Minimum} \{C_t(y) + g_{t+1}(s+y-d)\} \qquad t=1,\ldots,T \quad (5)$$

$$g_{T+1}(0) = 0 \quad (6)$$

$$g_{T+1}(s) = M \quad \text{for } s > 0 \quad (7)$$

where $s = 0, e, \ldots, d_1+d_2+\ldots+d_T$, M is a very large number, and the minimization is over only nonnegative values of y in the range $d_t - s \leq y \leq d_1+d_2+\ldots+d_T - s$. We have made the rather arbitrary assumption that excess capacity available at the end of the planning horizon is zero.

The dynamic programming formulation for Problem II possesses T stages and $(d_1+d_2+\ldots+d_T)/e$ states. For problems with less than 10 time periods and 1000 states, solution times of no more than 30 seconds CPU time on an IBM 370/165 would be expected. Thus, the total time to solve the Feeder Cable Expansion Problem would be under 1 minute; a very acceptable cost to solve a problem with such a high economic value.

One final step in the solution process is required. The solution to Problem II only indicates the number of line pairs required, not the actual cable selection. However, in solving Problem III we did compute what the cable selection must be for each possible level of installation. This information is stored in the vectors $h_R(y)$ for each possible value of y. Thus, we need only reference these vectors to find what the optimal cable selection must be.

In summary, the solution to the telephone Cable Layout Problem can be obtained as follows:

1) The cost function C(y) is obtained by solving the dynamic programming formulation (2) - (4).

2) The cost function $C_t(y_t)$ is found from (1).

3) The solution to Problem II is found by solving the dynamic programming formulation (5) - (7).

4) Using the values of y_t obtained from the solution of Problem II and the vectors of cable size selection $h_R(Y)$, one finds the optimal selection of cables x_{tr}.

Conclusion

In this paper we presented a dynamic model of a telephone Feeder Cable Expansion Problem. The optimal expansion policy for a particular segment of a cable feed area was shown to be obtainable from a sequence of easily solvable dynamic programming problems. Because of the independence of each of the segments, the optimal policies for the segments can be combined to form an optimal policy for an entire cable feed area.

Footnotes

[1]The authors have chosen to ignore in this paper the complexities introduced by consideration of possible conduit exhaustion and overgauging. A heuristic procedure for dealing with these important problems is presented in [1].

A Decision-Support System for Managing

By Steven F. Maier, James H. Vander Weide

INTRODUCTION

When the cash manager arrives at his office in the morning, one of his first tasks is either to plan how to invest the firm's excess funds or to plan how to finance its shortfall. Given the shape of the yield curve and an interest rate forecast, complex questions such as the following must be addressed: Is the firm better off investing in a 90-day CD or 30-day commercial paper? If interest rates are expected to rise, is the firm better off floating longer-term commercial paper at existing rates or rolling over a sequence of short-term paper at increasing rates? If the cash manager invests long now and finances next period's cash requirements with short-term borrowing, how much will the firm stand to lose if interest rates rise? The cash manager's answers to these questions can have a significant effect on the firm's financial performance.

STEVEN F. MAIER is associate professor of business administration at the Fuqua School of Business, Duke University. He has written some 30 journal articles in the areas of cash management, forecasting, financial planning and investments. He is also president of University Analytics, a firm specializing in research and development for the banking industry. He is co-editor of the ***Journal of Cash Management.***

JAMES H. VANDER WEIDE is associate professor of business administration at the Fuqua School of Business, Duke University. His research interests are in the area of the utility regulation and cash management. He has written over 20 published articles. He is the president of the Utility Financial Services, a consulting firm specializing in cost of capital analysis for regulated utilities, and an associate editor of the ***Journal of Cash Management.***

OVERVIEW

This paper describes an interactive, short-term financial planning model that provides answers to the kinds of questions raised above. Although the model is based on a sophisticated linear programming algorithm, its day-to-day use is readily understandable to the nontechnical cash manager. The key to ease of use is reducing interaction with the model to conversational responses via a computer terminal. A series of questions is asked about expected cash flows, current and forecasted interest rates, and any financial policy constraints the firm may have. The model then evaluates the various alternatives, and reports on the financial strategy that maximizes the future value of the portfolio and simultaneously satisfies all the firm's financial policy and cash flow constraints. Since the answer is reported in a matter of seconds, the user can explore further the economic tradeoffs inherent in this decision process by changing some of the model's parameters and constraints.

The model that we describe here has been implemented at General Telephone Company of the Southeast (GTSE), headquartered in Durham, North Carolina[1]. With few exceptions, GTSE is a net borrower of short-term funds, with commercial paper and master notes currently being the least expensive sources. Quick and accurate comparisons of master notes and various maturities of commercial paper have typically been difficult tasks, due primarily to the uncertainty of future interest rates, and the number of financing alternatives available. Their Short-Run Financial Planning Model has allowed GTSE to quantitatively analyze their borrowing alternatives in a timely fashion, in ways that were previously impossible.

THE SHORT-RUN FINANCIAL PLANNING MODEL

The Short-Run Financial Planning Model is a user-oriented version of the type of models formulated in Robichek, Teichroew and Jones (6), Mao (3), Orgler (4), Pogue and Bussard (5), Srinivasan (7), Maier and Vander Weide (2) and Austin, Maier and Vander Weide (1). Three primary characteristics differentiate the model reported here and used at GTSE from these previous formulations:

1. An enhanced version of the model has also been implemented recently at the bank of Montreal. It is available to corporate customers under the product name CALCULINE™.

a Short-term Financial Instrument Portfolio

1. Interactive Efficient Data Entry. The Short-Run Financial Planning Model has been programmed in an interactive mode that greatly reduces the amount of work involved in inputting data and checking for errors. The user can input all necessary data and explore several economic scenarios in a session lasting no longer than 20-30 minutes. In fact, once the model has been run the first time, the user can evaluate a particular decision problem in as little as 10 minutes.

2. New Features. The Short-Run Financial Planning Model has the capacity for handling a number of practical problems such as variable maturities, instruments that mature beyond the planning horizon, borrowing and investment maturity mismatches, and the possibility of arbitrage that are ignored in the previous contributions.

3. Current Status. The model provides reports on the characteristics of the firm's current portfolio of investment/borrowing instruments and automatically incorporates these characteristics into its constraints. The ability to automatically incorporate the cashflows from maturing securities in the firm's current portfolio is especially useful when the size of the dollars to be invested (borrowed) are small compared to the size of the existing portfolio.

ACKNOWLEDGEMENT

We wish to acknowledge the very substantial contribution of Jerry Austin, treasurer, General Telephone of the Southeast; Jim Grenfell, assistant treasurer of GTSE; and Larry Ray also of GTSE. Without their continuing support and assistance this work could not have been done.

[illegible]

The Short-Run Financial Planning Model is user-oriented. All information is entered via computer terminal in a time-sharing conversation. Since data from previous runs is stored, the model is particularly easy to use, once the first case has run. Only data changes need be entered on subsequent runs.

The input is conveniently grouped into six types:

Period Duration and Cash Flow Projection

The cash manager must specify the starting date of each time period within the planning horizon. He is also asked to specify which cash flows will be expected at the beginning of each time period within the horizon. The current model specification allows for a maximum of 25 time periods, with no limitations on the length of these periods. Cash flows may be either positive or negative.

We have found that it is best to keep the first few periods in the time horizon relatively short. For example, it is frequently convenient to use daily periods for the first few days, followed by a three-day period corresponding to a weekend. Later periods can be longer, often a week or two. It is also helpful to have one final period of relatively long duration to incorporate the firm's long-run cash flow and interest rate projections.

Instrument Description

The second input section presents a description of the available investment/financing instruments. Each instrument is described by name, maturity length, yield, and interest rate projection.

The maturity may be specified as a constant (e.g., a 91-day Treasury Bill would be specified as 91 days.) Since some financial instruments may have the same yield over a range of possible maturities, the model also permits the user to specify a range. For example, commercial paper with a yield of 9.5 percent could be purchased with a maturity of between 15 and 37 days.

The yield on an instrument is always computed as if the interest will be paid upon maturity. If the instrument is sold or bought at a discount, the discount rate can be specified and the model will automatically convert the discount rate of interest to the interest yield, as if the interest had been paid at maturity.

Flexible maturities and user-selected lengths for the time periods within the planning horizon cause unique problems to the construction of a model. In particular, one must deal with instruments that mature in the middle of a planning period. (Note that in a linear programming formulation only investment and borrowing that takes place at the start of an investment period are under model control.) In order to bridge from a mid-period maturity, the model takes two actions. First, if the instrument can be rolled-over, the model will automatically do so until the start of the next planning period is reached. The second action depends on whether the maturing instrument is an investment or borrowing. If the funds are in a maturing instrument, the system automatically puts the money into an over-night repurchase agreement and rolls this over to the next decision point. If a borrowing instrument is maturing in the middle of a period, then as of the date of the just previous decision point, money is set aside in a repurchase agreement, which with compounding will just equal the amount of the required repayment. These actions preserve the unique characteristics of both flexible maturities and time period lengths without overly distorting the reality of how portfolio managers actually in-

vest their financial instrument portfolios.

Interest-Rate Projections

The cash manager can specify an interest rate projection as a single interest rate projection (and use it to modify the yields on a group of investment instruments), or he can specify an independent interest rate projection for each of his investment or borrowing instruments.

The interest-rate projections incorporate into the model the cash manager's forecast as to the movement of interest rates during the planning horizon. The model using this information can then help the cash manager select whether to invest/borrow long or short. This involves looking at economic tradeoffs such as whether paying a premium for longer term borrowings is justified if your expectation is that interest rates will increase.

Borrowing and Investing Limits

The model allows a cash manager to limit the amount of borrowing or investing associated with any instrument or group of instruments. This limit allows him to incorporate judgments about the risk of various instruments, or to include company policy restrictions, such as "do not invest more than $3,000,000 of our portfolio in commercial paper."

Average Maturity Constraints

Upper and lower limits may be placed on the average maturities of the borrowing and/or investing side of the portfolio. This type of constraint is useful in limiting the degree of interest rate risk to which the firm is exposed. Professional investment managers often refer to a portfolio with differing average maturities of the investment and borrowing instruments as a "mismatched book." These constraints allow limits to be placed on the level of mismatch the company is willing to expose itself to. In the absence of such constraints, and with a normal shaped yield curve, the model would tend to always invest long and borrow short, which at times can produce a severely mismatched book.

Ratio Mix Constraints

Ratio mix constraints are similar to borrowing and investing limits, except that the bounds are specified as percentages rather than dollars. These constraints enable the cash manager to further define personal or company policy restrictions. For example, a constraint can be included to keep the ratio of bank borrowing to commercial paper at 50-50. A constraint of this form can be used to determine the cost of maintaining good bank relationships, when commercial paper appears to be significantly cheaper.

OUTPUT REPORTS

The Short-Run Financial Planning Model provides several types of output reports.

Cost Summary

The cost summary gives four types of information for each period (Exhibit 1):

- *period length*
- *cash flow projection*
- *interest expense*
- *cumulative interest expense.*

The number of days in the period and the projected cash flows are user-specified. The interest expense takes into account all instruments purchased or sold during the period, and all instruments which were activated before the start of the period and will mature at some later date. (A negative interest expense indicates interest earned.) The cumulative interest expense is the interest expense for the current and all previous periods.

Action Summary

The action summary, (Exhibit 2) lists eight components for each instrument bought or sold:

- *date on which the action is initiated*
- *instrument name*
- *type of action (buy or sell)*
- *amount of capital involved with the original purchase/sale of the instrument*
- *maturity date*
- *maturity value of the instrument*
- *yield of the instrument*

An instrument is only listed in this report on the day the initial action is taken. (To obtain a list of both initial and concluding actions within a period, a separate detailed report is available, although not shown in this paper.)

The "action" column indicates, with a "B" or "S," whether the instrument was bought or sold. The action date is the first day of the period in which the instrument is activated and the maturity date is the day of maturity.

The instrument yield is set initially as part of the instrument's description and can be revised by the user-defined interest rate projection.

Interest Rate Summary

Exhibit 3 gives an example of the Interest Rate Summary Report, showing in matrix form the yield of each instrument at the start of each period. The instruments are listed across the top of the matrix; the first four characters in the instrument name are used as an identifier. The first column in the matrix lists the starting date of the period.

With this information, the cash manager can check how his interest rate projections have modified the yield on each instrument. If there was no projection for the instrument, the same yield will appear throughout the column.

For instruments purchased at the start of a planning period, the yield can be found directly in this report. For instruments purchased in the middle of a planning period, such as would occur due to an automatic rollover, the yield is taken as a linear extrapolation of the yields given in this report.

Risk Summary

The risk summary (Exhibit 4) prints the average maturities of the portfolio for each period in the planning period. In addition to the starting date of the period, the following data is given:

- total dollars borrowed as of the start of the period
- average borrowing maturity as of the start of the period
- total dollars invested as of the start of the period
- average investment maturity as of the start of the period

This report is used to monitor the mismatch for the portfolio.

Input Summary

The input summary lists the data in a particular model file, giving users a consolidated look at all additions and deletions made during a computer session. It includes information in six major input categories: (1) period duration and cash flow projection; (2) borrowing and investing limits; (3) instrument description; (4) interest rate projections; (5) average maturity constraints; and (6) ratio mix constraints.

BENEFITS FROM USING THE MODEL

The Short-Run Financial Planning Model has provided GTSE with important ways to use its cash resources efficiently.

First, the model makes a cash manager sensitive to variables which affect his day-to-day borrowing decisions. This in turn leads to increased awareness of economic trade-offs associated with short-run financial decision making.

Second, the model provides a means of comparing alternative instruments on the basis of "effective" vs. "posted" interest rates. This is especially important for GTSE because of its heavy reliance on commercial paper, which is quoted on a discount basis.

Third, the model helps the cash manager to quickly and efficiently make comparisons of borrowing instruments which have variable maturities, providing a quantitative measure and the expected value of different financing stategies. This important feature allows a cash manager to analyze risk/return relationships.

Finally, the model's flexibility allows identification of the strengths and weaknesses of the present cash management system and forecasting methods, and offers ways to improve them.

GTSE EXPERIENCE

General Telephone of the Southeast has found the model to be a valuable teaching and budgeting aid. It provides a simple, effective way to budget short-term interest payments within a particular cash flow and interest rate scenario. The model will also quickly measure the impact of cash flow/interest rate variances on total interest expense. As a teaching tool, the model illustrates basic techniques and gives GTSE users an appreciation for the investment/borrowing instrument selection process.

SUMMARY

The Short-Run Financial Planning Model has allowed GTSE to qualitatively analyze a multitude of potential borrowing options in a timely fashion, in a way which was heretofore impossible. Although planning models are by their very nature complex, the use of a time-sharing com-

puter model gives near instant answers to complex questions involving interest rate forecasts, cash flow requirements, and investment opportunities.

Experience to date has provided certain keys to when the Short-Run Financial Planning Model can prove useful, including:

Size. The larger the investment/borrowing portfolio, the more likely fine tuning by a planning model will make sense.

Yield Differences. On the investment side the model tends to cause a lengthening in portfolio maturity, while on the borrowing side, it tends to shorten portfolio maturity. This results from better synchronization between cash inflows and outflows, with a corresponding reduction in the overnight liquidity pool. If the investment environment is such that changing the portfolio maturity can improve yields, this can more than pay for the modeling effort.

Investment Restrictions. If the cash manager is laboring under severe restrictions relative to the investments or borrowings he can make (e.g., only invest in T-Bills or C.D.'s from the 50 largest banks), the model can be used to demonstrate the cost of such a restrictive policy.

Exposure Management. Lengthening a portfolio of investments or borrowings incurs greater risk because interest rates may move against you. If a firm is contemplating such a move in order to take advantage of current yields, the model can quantify the risk if it should guess wrong on the future course of interest rates.

In summary, the Short-Run Financial Planning Model can provide answers instead of guesses to complex and important investment problems.

Abstract

We examine how universal service provisions and price restrictions across markets impact strategic entry and pricing. We develop a simple multi-market model with an oligopolistic (profitable) urban market and entry auctions for (unprofitable) rural service. Cross-market price restrictions induce a firm operating in both markets to become a 'softer' competitor, thus placing the firm at a strategic disadvantage. When we account for entry incentives and strategic bidding, the downstream strategic disadvantage becomes advantageous, leading to higher prices and profits. Price restrictions may also put outside firms, even relatively inefficient ones, at a strategic advantage. © 2002 Elsevier Science B.V. All rights reserved.

1. Introduction

We observe many regulated market environments in which the variation of prices across markets and market segments is restricted. Typically, these price restrictions are associated with universal service goals and they arise when the

price differentials expected to prevail in an unregulated setting are deemed unacceptable by policymakers. Familiar examples of industries with universal service requirements are postal delivery, railroad transport and telecommunications; related cross-market price constraints are also observed in a variety of other markets.[1] Liberalization in many regulatory environments, however, has exposed profitable markets to entry and competition. As discussed by Laffont and Tirole (2000) and others, liberalization has raised important questions regarding the coexistence of price constraints across markets, competition, and the goal of universal service, as many markets and segments are inherently unprofitable on a stand-alone basis.[2]

In a classic analysis, Leontief (1940) develops the theory of multi-market monopoly under cross-market price restrictions. Armstrong and Vickers (1993) introduce competition and examine the effects of price discrimination when an incumbent firm faces a (price-taking) entrant in a profitable market while the incumbent also serves customers in a separate market. A ban on price discrimination across the incumbent's markets, which is often part of a universal service requirement, causes the incumbent to be less aggressive in response to entry. The ban on price discrimination also has a significant impact on the scale of entry in equilibrium. We also examine the impact of cross-market price constraints (a ban on price discrimination) but introduce strategic interaction between competitors.

We focus on the issue of firm selection for a second, inherently unprofitable, 'rural' market and the strategic linkage to a profitable 'urban' market where there is oligopolistic competition. In particular, we examine the use of an auction to determine which firm will supply the unprofitable rural market. As discussed by Armstrong (2000) and Laffont and Tirole (2000), there is significant policy interest in the potential for awarding the right to serve markets via auctions in which bidders compete on requested subsidy levels.

We analyze the strategic implications of universal service requirements and related cross-market price restrictions with a simple model involving oligopoly competition and two markets. Oligopoly competition takes place in a profitable urban market and the resulting urban market price determines the ceiling (under

[1] Universal service provisions exist in several other markets (e.g., a Federal subsidy program was established following deregulation in the Airlines industry to support 'Essential Air Service' to rural, regional airports in the US). In general, cross-market price restrictions arise in a variety of contexts and, even when no formal entry auctions exist, strategic entry incentives may be affected: in international trade, anti-dumping provisions involve a comparison of prices across countries (Prusa, 1994); in pharmaceutical markets, countries often employ global reference pricing and link their domestic prices to those observed abroad (Lanjouw, 1997); and systems like Medicaid involve most-favored-customer rules (Scott Morton, 1997).

[2] According to Laffont and Tirole (2000), p. 218, ''Universal service is a knotty and explosive problem. It has been (or will be) a central issue in the political debate surrounding regulatory reform in all network industries and in most countries.''

TAW_R_COCDR1#80Attachment
Page 470 of 739

universal service) for the rural market price. The strategic element that matters for our analysis is that urban market firms can influence or manipulate the relevant prices via their strategic choices. A homogeneous good duopoly with quantity-setting (as in Cournot competition) has this property and, for simplicity, we adopt this as the mode for strategic choice in the urban market.[3]

The rural market is inherently unprofitable due to a large fixed cost. Thus, no firm would independently seek to enter this market. Supply in this market is determined by the outcome of bidding in an upstream auction in which one firm becomes the single supplier to the rural market. Bids take the form of subsidy requirements and the selected firm is the low bidder (smallest subsidy).

The model provides a simple equilibrium framework for assessing the strategic implications of universal service requirements. First, we examine the direct impact of cross-market price constraints under universal service on prices, quantities and profits in each of the urban and rural markets. Next, we employ these market outcomes to analyze the bidding incentives for the rural market auction. The advantage of this approach is that market structure and bidding outcomes are endogenously determined by the underlying demand and cost structure. Finally, we extend the analysis to examine bidding competition and market structure when 'outside' firms (i.e., not active in the urban market) also bid in the rural market auction.

Our main results are as follows. With regard to direct effects on the two markets, we find that universal service requirements create a strategic link between the urban and rural market. This link arises because a firm that supplies both markets would like to set a rural price in excess of the oligopolistically determined urban price and, as a result, the reaction function of this firm shifts in the direction that makes this firm a 'softer' competitor in the urban market. The shift, which is downwards under quantity-setting, leads to higher equilibrium prices in both markets relative to unconstrained oligopoly competition. The 'softer' firm benefits in the rural market but it suffers in the urban market as the competing firm expands and earns higher profits. Thus, a firm supplying both markets is at a strategic disadvantage relative to an urban market competitor.

Equilibrium bidding and the resulting subsidy in the rural market auction must reflect this strategic disadvantage. Since a firm would prefer to 'lose' the rural auction and gain the stronger position in the urban market, the equilibrium subsidy contains a premium to compensate for the strategic disadvantage. As a result, once the subsidy is included, both firms earn higher profits relative to those under pure oligopoly competition in the urban market. The key insight is that the higher price under universal service leads to greater joint profits for the competitors and the auction, via the subsidy, allows a share of these gains to accrue to the firm that

[3] We also discuss how our results extend to other settings, such as differentiated price-setting (Bertrand) competition and quality competition.

TAW_R_COCDR1#80Attachment
Page 471 of 739

supplies both markets. Thus, the strategic disadvantage created by universal service requirements is advantageous for urban market competitors once we account for the equilibrium incentives to bid for the rural market.

The presence of outside firms in the rural market auction affects bidding and the resulting market structure in several important ways. The critical feature is that an outside firm cannot directly affect the urban market price and, consequently, when an outside firm wins the auction, the strategic link between prices in the two markets disappears. This has an important implication for bidding incentives as the identity of the winning firm now matters to an incumbent urban market firm when it loses the rural auction. Among other results, we show when this leads to a less efficient outside firm winning the rural market auction.

Our analysis rests upon a price link across markets and is therefore closely related to the general issue of multimarket oligopoly. The idea that production in one market can affect strategic incentives in another market is emphasized by Bulow et al. (1985). The strategic link in our analysis, however, does not arise as a consequence of cost or demand interrelationships across markets. Indeed, we abstract away from any such interrelationship in order to focus exclusively on the strategic implications of the price restriction.

DeGraba (1987) also recognizes how cross-market price constraints can make firms softer competitors. The focus is different, however, as DeGraba shows that once firms become softer (price) competitors they may adjust their locations and, as a result, prices may decrease when a cross-market price constraint is present. In addition, he does not examine entry incentives, a primary consideration in our analysis.[4]

Our analysis involves an entry auction for determining the rural market supplier. Consequently, the issue of whether a multimarket oligopoly arises (an insider wins the auction) or not (an outsider wins) is determined endogenously. Further, the valuations of insiders and outsiders with respect to the rural market feature external effects: a losing bidder is affected by the identity of the winning bidder. Thus, our entry auction is related to recent work on auctions and, in particular, Jehiel and Moldovanu (1996, 2000) who examine bidding under external effects. In our case, the asymmetry of external effects is because an urban market insider prefers that a competing insider wins the auction rather than an outsider.

The basic model is described in Section 2 and analyzed in Section 3. In Section 4, we examine bidding when outside firms can participate. Section 5 discusses welfare effects. We consider extensions and conclude in Section 6.

[4] Our paper is also related to the problem of introducing competition into regulated markets (see Biglaiser and Ma, 1995; De Fraja, 1997; Laffont and Tirole, 1993; Wolinsky, 1997, who also provide additional references).

TAW_R_COCDR1#80Attachment
Page 472 of 739

2. The Model

There are two markets, U (urban) and R (rural) and two firms, A and B. Demand in the U market is $D^{U}(p) = 1 - p$ and in the R market $D^{R}(p) = b(1 - p)$, where p is the market price and $b > 0$. Thus, while both markets have a common price intercept of $p = 1$, the slope coefficient of b allows rural demand to be smaller or larger than urban demand. In many situations, we expect the rural market to be the smaller market.[5]

The fixed cost of any given firm is $F^{U} > 0$ in market U and $F^{R} > 0$ in market R. There is a constant marginal cost $c \geq 0$, and this is the same for both firms and both markets.[6] Naturally, we assume that $c < 1$ so that, ignoring fixed costs, it is always profitable (and efficient) to supply some amount to each market.

2.1. Benchmarks

Consider first the case where the two firms compete in a Cournot fashion in the U market. Standard arguments yield a unique equilibrium with quantities $q^{c} = (1 - c)/3$, price $p^{c} = (1 + 2c)/3$, and per-firm profit

$$\pi^{c} = (1 - c)^{2}/9 - F^{U}. \tag{1}$$

We assume that the fixed cost in the U market is sufficiently low to allow $\pi^{c} > 0$.

Consider now a monopolist operating only in market R. The monopolist would maximize $Q(1 - Q/b) - cQ$ by choosing output $b(1 - c)/2$ with price $(1 + c)/2$ and profit

$$\Pi^{M} = b(1 - c)^{2}/4 - F^{R}. \tag{2}$$

We assume that F^{R} is sufficiently large that $\Pi^{M} < 0$. This assumption implies the need for subsidies if the government wants consumers in this market to be served.

2.2. The game

We consider a simple complete information game with the following timing.

1. Firms A and B choose bids s^{A} and s^{B}. These bids represent lump-sum subsidies that the firms ask from the government in order to serve market R.

[5] The analysis, which extends readily to linear demands with different intercepts, is streamlined by specifying a common intercept since this eliminates cases in which the price constraint does not bind.

[6] We assume that marginal cost is the same in order to focus on the effects of differences in demand and fixed costs across markets. Such differences are often substantial in reality.

TAW_R_COCDR1#80Attachment
Page 473 of 739

2. The lowest bidder (smaller subsidy required) wins, receives a subsidy equal to the winning bid, incurs the fixed cost F^R and becomes a monopolist in the R market. 'Ties' among symmetric bidders are resolved by a coin toss and ties in other cases are resolved by awarding the rural market to the bidder with the highest payoff.[7] The price in the R market is determined as in 4 below.

3. Firms A and B choose quantities q_A and q_B for the U market. The price in the U market is then determined as $p^U = 1 - q_A - q_B$.

4. The monopolist in the R market can then choose a price that cannot exceed the price determined in the U market, that is, $p^R \leq p^U$.

5. Each firm's payoff is the sum of its profits in the two markets, including any subsidies.

We solve for a subgame perfect equilibrium of this game, focusing on pure strategy equilibria in the bidding stage.[8]

3. Analysis

We proceed from the end of the game-tree back towards the beginning.

3.1. Step 1: pricing in the R market

As we show below, the $p^R \leq p^U$ constraint is binding in equilibrium. In other words, the monopoly price in the R market is higher than the equilibrium price in the U market when one firm operates in both markets. Thus $p^R = p^U$.

[7] In a complete information setting, auction equilibria typically involve a tie either because bidders are symmetric or because the bidder with the strongest strategic position bids so that the next strongest bidder is indifferent between winning and losing. Our tie breaking rule follows the literature (see, e.g., Milgrom, 1987).

[8] Some remarks about the model are appropriate at this point. First, the adopted timing of events is the one that makes the cross-market constraint operate in a natural way. An alternative sequencing would be to have the firm that operates in both markets choose the quantities it supplies in each market at the same time that the other firm chooses its U market quantity. However, this would create the problem of how to impose the price constraint in the R market. Second, the multi-market firm should not be viewed as a price-taker in the R market. Given the cross-market price constraint, the firm is free to set any price in the R market up to the ceiling. More importantly, the ceiling is endogenous with respect to the firms' actions: the multi-market firm can and does adjust its U market choices to raise the ceiling price for the R market. Finally, the Cournot structure for the U market only serves to streamline the analysis and allows us to consider a homogeneous good for which the cross-market price constraint is unambiguous (R market buyers purchase the same good at the same price as U market buyers). As an alternative strategic mode, we could employ price setting (differentiated Bertrand). While, as noted below, this does not alter the basic strategic link between the U and R markets, it does introduce additional issues such as how to interpret the cross-market price constraint when products are differentiated.

TAW_R_COCDR1#80Attachment
Page 474 of 739

3.2. Step 2: quantities supplied in the U market

Denote by q_1 the quantity supplied in the U market by the firm that only operates in the U market and by q_2 the quantity supplied in the U market by the firm that operates in *both* markets. Given the quantities supplied in the U market, the prices are $p^R = p^U = 1 - q_1 - q_2$. Then, market profits gross of fixed costs and subsidies are: for the firm that operates in both markets $[(1 - q_1 - q_2)q_2 - cq_2] + [(1 - q_1 - q_2)b(q_1 + q_2) - cb(q_1 + q_2)]$ or, equivalently, $(1 - q_1 - q_2 - c)[q_2 + b(q_1 + q_2)]$, and for the firm that operates only in the U market $(1 - q_1 - q_2 - c)q_1$.

We can then derive the reaction functions

$$r^1(q_2) = \frac{1 - c - q_2}{2} \quad \text{and} \quad r^2(q_1) = \frac{1 - c - q_1}{2} - \frac{bq_1}{2(1 + b)}, \tag{3}$$

which yield the equilibrium quantities

$$q_1^* = (1 + b)\frac{1 - c}{3 + 2b}, \quad q_2^* = \frac{1 - c}{3 + 2b}, \tag{4}$$

and equilibrium price

$$p^* \equiv 1 - q_1^* - q_2^* = \frac{(1 + b)(1 + c) + c}{3 + 2b} = p^U = p^R. \tag{5}$$

It is now easy to check that the price constraint is indeed binding:

Remark 1. *p^* is lower than the monopoly price in the R market.*

This follows directly from a comparison of p^* with the monopoly price $(1 + c)/2$ upon noting that $c < 1$. We now summarize how the outcome in the urban and rural markets under the price constraint compares with the benchmark of Cournot outcomes in the urban market. A direct comparison of the appropriate terms shows that:

Proposition 1. *Relative to the Cournot outcome,* (*i*) *when one of the U market firms also operates in the R market, equilibrium in the U market involves a higher price and lower aggregate quantity*: $p^* > p^c$ *and* $q_1^* + q_2^* < 2q^c$, *and* (*ii*) *the firm that operates in both markets supplies a lower quantity in the U market while the firm that operates only in the U market supplies a higher quantity*: $q_2^* < q^c < q_1^*$.

Intuitively, the firm that operates in both markets would like to relax the R market price constraint and, as a result, it would like a higher price in the U market. To accomplish this, it is willing to supply a lower (than the Cournot level) quantity in the U market. In other words, the firm that operates in the U market is now ‘softer’ (relative to Cournot competition). This is evident from the fact that

TAW_R_COCDR1#80Attachment
Page 475 of 739

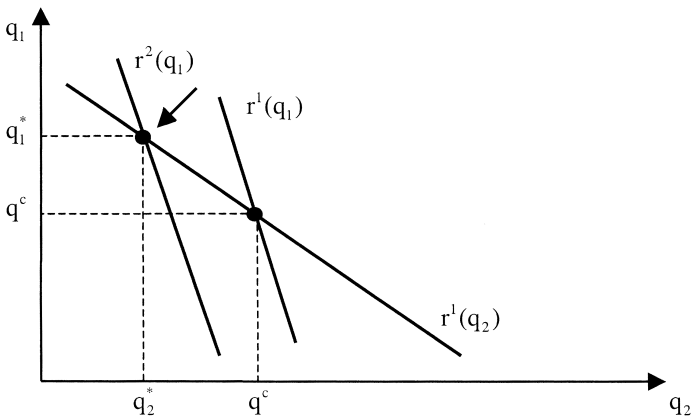

Fig. 1. Equilibrium quantities in the Urban market compared to the equilibrium with no cross-market constraints.

the reaction function r^2 lies below the reaction function under Cournot competition (see Fig. 1 and Eq. (3)). The U market competitor (firm 1) benefits from this effect and supplies a larger quantity.

Now, the equilibrium profit for the firm that operates only in the U market is

$$\pi_1^* = (p^* - c)q_1^* - F^{\mathrm{U}} = \frac{(1+b)^2}{(3+2b)^2}(1-c)^2 - F^{\mathrm{U}} \tag{6}$$

and profit for the firm that operates in both markets is

$$\begin{aligned}\pi_2^* &= (p^* - c)[q_2^* + b(1-p^*)] - F^{\mathrm{U}} - F^{\mathrm{R}} \\ &= \frac{(1+b)^3}{(3+2b)^2}(1-c)^2 - F^{\mathrm{U}} - F^{\mathrm{R}}.\end{aligned} \tag{7}$$

A direct comparison of (1), (6) and (7) yields the following result.

Lemma 1. *The profit of the firm that operates in both markets is lower than the per-firm U market Cournot profit and this, in turn, is lower than the profit of the firm that operates only in the U market*:

$$\pi_2^* < \pi^c < \pi_1^*. \tag{8}$$

The firm that operates in both markets has negative profit in the R market once we account for the fixed cost of F^{R}. Further, this firm supplies smaller quantity to the U market and has a lower profit there than its competitor. Thus $\pi_2^* < \pi_1^*$. $\pi^c < \pi_1^*$ follows from the fact that the firm that operates only in the U market increases both its price and its quantity when its competitor enters the R market.

TAW_R_COCDR1#80Attachment
Page 476 of 739

Now, $\pi_2^* < \pi^c$ is true for two reasons. First, firm 2 has a loss in the R market. In addition, firm 2's profit in the U market decreases when it enters the R market. Note that when 2 enters the R market the quantity it supplies to the U market decreases but the price increases. Direct calculations show that its U market profit drops from π^c to $(p^* - c)q_2^* - F^U = (1+b)(1-c)^2/(3+2b)^2 - F^U$. This follows by noting that $(p^* - c)q_2^* - F^U$ is equal to π^c for $b = 0$ and is decreasing in b.

3.3. Step 3: equilibrium bids

The total payoffs as functions of the bids s^A and s^B (and assuming equilibrium behavior in the continuation of play) are

$$v^i(s^i, s^j) = \begin{cases} \pi_1^* & \text{if} \quad s^i > s^j \\ \pi_2^* + s^i & \text{if} \quad s^i < s^j, \end{cases} \quad i, j = \text{A, B},$$

where π_1^*, π_2^* are calculated as above. Note that the bids represent required subsidies and an 'aggressive' bid (one that increases the chance of winning the auction) is a low bid.

Now we can determine the equilibrium bids:[9]

Proposition 2. *In equilibrium, each firm requires a subsidy equal to*

$$s^* \equiv \pi_1^* - \pi_2^* = F^R - b\left[\frac{(1+b)(1-c)}{(3+2b)}\right]^2 \Big/ 25 \tag{9}$$

and wins the auction with probability 1/2. *The total after-subsidy profit for each firm is* π_1^* (*which exceeds* π^c). *Further, the joint profit in the U market exceeds the Cournot level.*

A firm that operates only in the U market strictly prefers that its U market opponent also operates in the R market, because this makes the U market opponent a softer competitor in the U market. Consequently, the required subsidy in equilibrium is $\pi_1^* - \pi_2^*$, which is higher than $\pi^c - \pi_2^*$. In other words, the point of reference for the firm that loses the auction is not π^c but π_1^*. When a firm loses the auction then its competitor wins, and this is a desirable outcome for the firm. Thus, each firm is more 'demanding' with respect to the subsidy it requires.

[9] The proof is immediate. If it bids $s < s^*$, the firm wins the auction and receives total profit $s + \pi_2^* < s^* + \pi_2^* = \pi_1^*$. On the other hand, with a bid $s > s^*$ the firm loses the auction and has the same profit, π_1^*. Proposition 2 describes the unique pure-strategy outcome. A symmetric mixed strategy bidding equilibrium also exists, but it requires unbounded support for the bid distribution and so does not survive if there is a finite upper bound on the requested subsidy. For a related construction see Baye and Morgan (1999).

TAW_R_COCDR1#80Attachment
Page 477 of 739

The fact that equilibrium profit exceeds the Cournot level (if there were no link between the markets) represents a key effect in our analysis. The desire of the government to provide service to consumers in the rural market, in conjunction with the requirement that the rural price not exceed the urban price, can create a perverse incentive for each firm to lose the auction for the rural market in order to gain the more profitable position of serving only the urban market. Equilibrium bidding then leads to a subsidy that compensates for the strategic disadvantage associated with winning. As a result, both firms ultimately benefit and earn profit π_1^* which exceeds π^c (the profit level when no price constraint is imposed on the R market or, equivalently, the profit when U market firms are not allowed to enter the R market). Further, the urban market has higher prices and lower quantities relative to those of unconstrained oligopoly competition (Cournot) in the urban market.

The effects described above are valid for much more general settings than the simple model presented here. In particular, they hold for standard Cournot models with nonlinear demand and costs.[10] Further, the main effect is still present if there are more than two U market firms, as long as these have market power (of course, as the market power of each firm decreases, the incentive to manipulate the price becomes weaker). Finally, the effects of the price restriction are not dependent on the specifics of quantity-setting as the strategic mode. In a differentiated price-setting competitive interaction, the reaction function of the firm operating in both will also shift in the direction (up in the case of price-setting) associated with being a softer competitor.

4. Outsiders allowed to bid for the Rural market

Thus far we have focused on the interaction between the (two) firms that are active in the U market. We now introduce the possibility of entry into the R market by a firm that is not active in the U market, an 'outside' firm, for short. The critical difference is that an outside firm cannot directly affect or manipulate the price in the U market. In addition to being a useful benchmark for understanding the incentives of U market incumbent firms to relax the cross-market price constraint, the question of whether an insider or an outsider is expected to win the auction is an important strategic issue for firms in these markets as well as for policymakers. Our inquiry includes the question of whether an inside incumbent or an outsider is more likely to request a smaller subsidy and win the auction, as well as that of determining the strategic impact of an outsider on the bidding behavior of inside firms.

In order to focus on the implications of differences in strategic positions, we

[10] A sufficient condition is to have downward sloping reaction functions with a unique, stable equilibrium. We thank a referee for this suggestion.

TAW_R_COCDR1#80Attachment
Page 478 of 739

begin by abstracting away from any other differences between U market incumbent firms and outside firms; later, we discuss the impact of differences in technology. Thus, all firms face the same marginal cost of c and fixed cost of F^{R}. The game is as before with the only change being that outside firms can also submit bids at the same time as U market incumbents for the R market subsidy. We begin with the case of one outside firm and then proceed to the case of many outsiders (this corresponds to 'free entry' into the R market auction).

4.1. Comparing the profit differences

Consider first the subgame given that an outsider has won the bidding. In this case, neither of the duopolists in the U market has any cross-market incentive to manipulate the U market price. Thus, the price in the U market will be the Cournot price p^c, and each of these two firms will earn the Cournot profit, π^c. The price constraint binds on the outside firm and so p^c will also be the price in the R market.[11] The profit for the firm operating in the R market (before the subsidy) is then

$$(p^c - c)b(1 - p^c) - F^{\mathrm{R}} = \frac{2b}{9}(1 - c)^2 - F^{\mathrm{R}} \equiv -\tilde{\pi} < 0. \tag{10}$$

Thus, $\tilde{\pi}$ is the *loss* for the firm operating (only) in the R market. It follows that in order for the outsider to be willing to enter the R market, a subsidy of at least $\tilde{\pi}$ is necessary (the outsider's profit when not operating in the R market is normalized to zero).

In the subsequent analysis, we need to compare $\tilde{\pi}$ to $\pi_1^* - \pi_2^*$ (the bid subsidy demanded in equilibrium when only the U market incumbents can bid for the R market) and $\pi^c - \pi_2^*$ (the decrease in an insider's profit after entering the R market). From the previous analysis, a direct comparison of $\tilde{\pi}$ from (10), $\pi_1^* - \pi_2^*$ from (9), and $\pi^c - \pi_2^*$ from (1) and (7) yields:

Lemma 2. (*i*) $b \leq b_L \Leftrightarrow \tilde{\pi} \leq \pi^c - \pi_2^* < \pi_1^* - \pi_2^*$,(*ii*) $b_L < b \leq b_H \Leftrightarrow \pi^c - \pi_2^* < \tilde{\pi} \leq \pi_1^* - \pi_2^*$, *and* (*iii*) $b_H < b \Leftrightarrow \pi^c - \pi_2^* < \pi_1^* - \pi_2^* < \tilde{\pi}$, *where* $b_L \equiv (1 + \sqrt{13})/2 \simeq 2.3$ *and* $b_H \equiv 3(1 + \sqrt{2}) \simeq 7.24$.

Observe that in most applications we expect demand in the rural market to be less than demand in the urban market. Taking $b < 1$, the above result implies that an outsider will incur a smaller loss from supplying service to the rural market than will an urban market insider. Thus, assuming that production technologies and all other aspects of the firms are identical, outsiders are in a better strategic position to submit a more aggressive bid in the auction for the R market.

[11] Since $p^c < p^*$ and from Remark 1 the price constraint binds at p^*, it also binds at p^c.

TAW_R_COCDR1#80Attachment
Page 479 of 739

4.2. Equilibrium

We begin with the case of a single outsider who can bid for the R market. This allows us to isolate the effect of an outsider from that of competition among outsiders.[12]

Proposition 3. *Suppose that one outsider and the two firms active in the U market participate in the R market subsidy auction.*

(*i*) *If* $b \leq b_L$, *in equilibrium, all firms bid a subsidy of* $\pi^c - \pi_2^*$ *and the outsider wins. In equilibrium, the outsider has after subsidy profit* $\pi^c - \pi_2^* - \tilde{\pi} > 0$, *and each of the U market incumbents has profit* π^c.

(*ii*) *If* $b_L < b \leq b_H$, *in equilibrium, a U market incumbent wins with a bid of* $\tilde{\pi}$, *the outsider also bids* $\tilde{\pi}$, *and the other U market incumbent requires a subsidy higher than* $\tilde{\pi}$. *In equilibrium, the winning U market incumbent has after-subsidy profit* $\tilde{\pi} + \pi_2^*$, *the losing U market incumbent has profit* π_1^*, *and the outsider has zero profit.*[13]

(*iii*) *If* $b_H < b$, *in equilibrium, each of the U market incumbents bids* $\pi_1^* - \pi_2^*$ *and wins with probability* $1/2$ *while the outsider submits a higher bid.*

Proof. (i) In this case, Lemma 2 implies $\tilde{\pi} \leq \pi^c - \pi_2^* < \pi_1^* - \pi_2^*$. The outsider does not want to raise its bid because it would lose the auction and its profit would drop from $\pi^c - \pi_2^* - \tilde{\pi} > 0$ to zero. It also does not want to lower its bid since this would only decrease its subsidy. A U market insider does not want to lower its bid because it would then win the auction and its profit would decrease: a bid $s < \pi^c - \pi_2^*$ yields after-subsidy profit $\pi_2^* + s$, which is lower than π^c. Finally, raising the bid would not affect an insider's profit.

(ii) In this case, $\pi^c - \pi_2^* < \tilde{\pi} \leq \pi_1^* - \pi_2^*$. The outsider would still lose the auction if it asks for a higher subsidy and thus its profit would remain zero. Its profit would be negative if it bid less than $\tilde{\pi}$ and won the auction. By submitting a lower than $\tilde{\pi}$ bid, the losing insider wins and its after subsidy profit drops to below $\tilde{\pi} + \pi_2^*$ which is lower than the original profit of π_1^*, since for these parameter values $\tilde{\pi} \leq \pi_1^* - \pi_2^*$. Finally, if the winning insider asked for a lower subsidy, it would only decrease its profit by the amount of the subsidy reduction. If it asked for a higher subsidy, it would lose the auction and the outsider would win. This deviation leads to a profit of π^c which is lower than the original profit, $\tilde{\pi} + \pi_2^*$

[12] In practice, a large asymmetry could render other potential outsider firms irrelevant to the bidding competition, as when a prior R market incumbent has legal control of essential facilities (see Laffont and Tirole (1993, p. 260)).

[13] In this case, there is no pure-strategy equilibrium where the outsider wins or where an insider wins and both insiders have the same bid. There is, however, a symmetric mixed strategy equilibrium in which each insider mixes between $\tilde{\pi}$ and an arbitrary higher bid. Details are available from the authors upon request.

TAW_R_COCDR1#80Attachment
Page 480 of 739

because we have $\pi^c - \pi_2^* < \tilde{\pi}$. Thus, the proposed strategy profile is an equilibrium, with the losing insider making higher profit than the winning insider and the outsider disciplining the winning bid.

(iii) In this case, $\pi^c - \pi_2^* < \pi_1^* - \pi_2^* < \tilde{\pi}$. The outsider would make a large enough loss ($\tilde{\pi}$) if it entered the R market that its presence is irrelevant for the auction. The U market firms behave exactly as in Proposition 2. The outsider loses the auction and submits a high bid. If the outsider were to submit a bid lower than $\pi_1^* - \pi_2^*$, it would win the auction and its loss in the R market would be larger than the subsidy. □

Recall that we consider the case of small rural market demand to be the most likely scenario for most applications. Proposition 3(i) then implies that the strategic advantage of an outsider translates directly into the ability to win the R market auction at a subsidy level that involves a positive profit. Insiders then operate only in the U market. Note that it is the willingness of insiders to bid (and operate) in the R market that disciplines the bid subsidy and that, in equilibrium, the insiders are pushed to indifference.[14] In addition, a comparison of the profits for insiders indicates clearly that the insiders would prefer that outside firms be excluded from the rural market auction.

Suppose now that there are two or more outsiders. The only difference is that the presence of other outsiders disciplines the bid of each outsider and, therefore, in case (i) of the above Proposition, the winning bid cannot be higher than $\tilde{\pi}$.

Proposition 4. *Suppose that $n \geq 2$ outsiders and the two firms active in the U market participate in the R market subsidy auction. Then, if $b \leq b_L$, in equilibrium, all outsiders bid $\tilde{\pi}$ and each of the outsiders wins with probability $1/n$. Insiders can bid any number higher than $\tilde{\pi}$. In equilibrium, each outsider has after subsidy zero profit and each of the U market incumbents has profit π^c. If $b > b_L$ the equilibrium is as in Proposition 3.*

Propositions 3 and 4 suggest that, when firms are otherwise identical, an outsider is expected to win the auction when demand in the R market is not too large, whereas a firm active in the U market is expected to win if demand in the R market is high.

The key point here is that an outsider cannot manipulate the U market price, whereas a U market insider can. Therefore, an insider has an additional instrument at its disposal. We know that the price in the R market will be higher and the loss smaller if a U market insider operates there as compared to when an outsider does.

[14] In case (i) there is also a continuum of equilibria that differ from the one above in that the winning bid belongs to $[\tilde{\pi}, \pi^c - \pi_2^*)$. Similarly, in case (ii) there is also a continuum of equilibria with the winning bid in $[\pi^c - \pi_2^*, \tilde{\pi})$. Such equilibria are usually viewed in the literature as 'unreasonable' because they require the firm that submits the 'disciplining' bid to employ a weakly dominated strategy.

TAW_R_COCDR1#80Attachment
Page 481 of 739

Thus, if firms are otherwise identical, it appears that a U market insider always has an 'advantage' relative to an outsider. How can we then find that an outsider may win the auction? This is because, firstly, the intuition described above is not valid is a strategic framework. When an insider also operates in the R market, the U market price is not manipulated against a given choice of the other U market competitor in the U market. Rather, the equilibrium in the U market is shifted as both competitors alter their choices. The source of this shift is that the firm operating in both markets now behaves according to the reaction function r^2 rather than r^1. Thus, the value of being able to manipulate the U market price depends on the downstream incentives of the firm and the resulting interaction with the U market rival.[15] Secondly, an insider's point of reference in case it loses the auction is different from that of an outsider. An insider strictly prefers that its U market competitor also operates in the R market and therefore requires the larger subsidy of $\pi_1^* - \pi_2^*$ rather than $\pi^c - \pi_2^*$ in order to give up the opportunity to face a softer competitor. Thus, in the event that it loses the auction, an insider will still care about the identity of the winner. An outsider faces no such concerns.

4.3. Different costs

The above results imply that a firm can often submit a more aggressive bid purely because it has a more favorable strategic position than another firm (even if firms are otherwise identical). These results also imply that a less efficient firm may be able to win the auction:

Remark 2. *An outside firm may win the rural market auction simply because it has a stronger strategic position, despite having higher production costs than inside firms.*

For concreteness, suppose that b is not too high, so that an outsider has a strategic advantage ($b < b_L$). In addition, we now allow for different costs. Let $\bar{c}$ be the unit cost for an outsider (the analysis so far has assumed $\bar{c} = c$). Clearly, for $\bar{c} < c$ the previous analysis implies that an outsider will win the auction. Suppose now that $\bar{c} > c$, so that the insiders are more efficient.[16] Propositions 3(i) and 4 remain valid for a range of $\bar{c}$ above c and an outsider will still win the R market

[15] The loss for an outsider that enters the R market is $\tilde{\pi}$. The corresponding loss for a U market insider is $\pi^c - \pi_2^*$. As shown above, the loss in the U market for a firm operating in both markets may be greater than its gain in the R market and therefore we could have $\tilde{\pi} < \pi^c - \pi_2^*$. Note that if the incumbent could commit not to decrease its U market output, its total profit could never fall below $\pi^c - \tilde{\pi}$. But the fact that a firm's reaction curve shifts once it enters the R market makes it possible for π_2^* to be below $\pi^c - \tilde{\pi}$.

[16] Insiders may be more efficient due to economies of scope across multiple markets. Other factors, however, such as labor and capital structure inherited from prior regulatory policy, may disadvantage an insider.

TAW_R_COCDR1#80Attachment
Page 482 of 739

auction.[17] Thus, a (single) less efficient outsider is able to win the R market auction at a positive profit subsidy level whenever the advantage of a strong strategic position dominates the high cost disadvantage. Of course, with multiple outsiders, the bidding competition dissipates the profit from the subsidy, although an outsider still wins auction. Similar points apply for differences in fixed costs.

5. Welfare

It is useful to summarize here some basic welfare implications of our analysis. The discussion is based on our analysis of price and profit implications earlier in the paper. A first benchmark to which we can compare the policy of the cross-market price constraint and auction for the R market (and when only U markets insiders can bid for the R market) is an auction without any price constraint in the R market (then the winner of the auction charges the monopoly price in the R market — see Section 2.1). Compared to this benchmark, price falls to p^* from the monopoly level in the R market and it rises to p^* from the Cournot level in the U market (p^c). It is easy to verify that the increase in consumers' surplus in the R market is larger than the loss in the U market. The auction bid subsidy falls from Π^M (see (2)) to $\pi_1^* - \pi_2^*$, and both U market firms earn a higher profit level of π_1^*. Further, the sum of consumers surplus (over both markets) and profits (over the two firms) less the subsidy increases as the price constraint is introduced. Thus, for the familiar welfare measure consisting of a weighted average of these terms, introducing the price constraint will increase welfare as long as the weights on consumers surplus in the U compared to R market are not too far apart, a presumption which appears consistent with the goals of universal service.

Opening the auction to outsider bidding has direct welfare implications. Focus on the case of a 'small' R market. Then, outsider bidding causes the price to fall from p^* to p^c in both markets, directly benefiting consumers. Further, insider profits fall to π^c from π_1^* as does the auction subsidy. Clearly, allowing an outsider to bid for the R market in this setting breaks the strategic link with the U market. The outcome then is equivalent to a second benchmark for our analysis, that of a policy that fixes the R market price to p^c. Moving from one to multiple outsiders then disciplines the bidding of outside firms (and the resulting profit) without changing prices and consumers surplus or insider profits. Therefore (and although advice to policy makers cannot be precise if based only on a simple model like ours) it appears that, when there is a cross-market price constraint,

[17] This is because $\pi^c - \pi_2^*$ is independent while $\tilde{\pi}$ is decreasing in the outsider's marginal cost. At $\bar{c} = c$ we have $\tilde{\pi}$ less than $\pi^c - \pi_2^*$ by a finite amount. Thus, we must have $\tilde{\pi} \leq \pi^c - \pi_2^*$ for a range of $\bar{c}$ above c.

TAW_R_COCDR1#80Attachment
Page 483 of 739

opening the auction to outsiders may help neutralize the adverse effect of firms' strategic behavior on consumer surplus.[18]

6. Extensions and conclusion

Our analysis shows how, when a firm operates in both markets, the incentive to relax the cross-market restriction makes the firm a 'softer' competitor and places the firm at a strategic disadvantage relative to other urban market competitors. Entry incentives must account for this disadvantage and strategic bidding results in an equilibrium subsidy that contains a compensating premium. Consequently, the downstream strategic disadvantage becomes advantageous for insiders, leading to higher prices and profits. Further, the existence of a strategic disadvantage for a firm operating in both markets makes it important to distinguish between inside and outside firms. An entry auction in this setting involves external effects: a losing inside firm is affected by the identity of the winning firm since this determines whether the losing firm will face a weak or a strong competitor in the urban market. Importantly, we find that an inefficient outside firm may win the rural market auction.

An assumption of the model that can be easily relaxed is that firms have the same technology. For example, the analysis can be reproduced in a straightforward way when the incumbents have different marginal costs. In this case we find that, as expected, it is the more efficient of the two firms that requires a smaller subsidy and enters the R market.

Further, the number of firms in the U market can be endogenized. Suppose that two Cournot competitors make positive profit in the U market but three would have a loss. If one of these two firms entered the R market, it would decrease its U market output and, thus, increase the U market price and its R market profit. But with the higher price in the U market it is conceivable that further entry in the U market has become profitable. This further entry creates a force that would tend to decrease the price back towards its original level. The analysis can be modified to include this case, with the incumbent firms taking into consideration the possibility of further entry when they choose their output levels. While we do not explicitly model this possibility in the paper, it is important to keep in mind with respect to entry and policy issues that, if the price increase in the U market is very high, additional firms may find it profitable to enter.

[18] Concerning our discussion of cost differences above, note that it is not obvious that the government should necessarily award the R market to the lowest bidder versus employing some type of bidder handicap system. The reason is that, although the outsider may require a larger subsidy to operate in the R market (if its cost is sufficiently higher), the price (in both markets) is lower when the outsider operates in the R market than the price when one of the U market insiders operates in the R market. Another way to think about this is that when a U market insider operates in the R market, there are additional market distortions.

TAW_R_COCDR1#80Attachment
Page 484 of 739

Universal service provisions often also require that the quality of services in rural markets be comparable to that provided in urban markets. The logic of our model also applies to the case where quality is endogenous. This case is of interest since imposing a cross-market price constraint is less important if the quality levels are allowed to differ substantially, and is particularly important in markets with rapid technical change. The model could be modified as follows. Suppose that firms compete in both quantity and quality, and that the cross-market constraint dictates that the product has to be provided in the R market at a price not higher and a quality not lower than the U market levels.[19] Then, a firm operating in both markets may have an incentive to supply lower quality to the U market to increase profit in the R market.

Finally, we have not considered how the government finances the subsidy. In principle, of course, if welfare maximization is the goal, the government should choose some tax that minimizes the resulting distortions. Often, this subsidy can be financed by some tax on the firms operating in this industry, essentially creating a cross-subsidy from the profitable (U) to the unprofitable (R) segments of the market. For example, there may be a tax on the revenues of firms. The main idea is that firms contribute part of their revenues to this fund, and the collected revenue is used to finance the subsidy to firms serving the unprofitable segments of the market. Thus, it is of interest to discuss briefly how such a scheme might affect competition from the point of view of our model. In a formal treatment of the issue, the tax rate should be treated as endogenous (because the tax must produce sufficient revenue to cover the subsidy, that is, revenue should equal the winning bid in the R market auction). This has implications not only for bidding strategies, but also for the way competition takes place. Since the main goal of the paper is to examine how the cross-market price constraint affects the strategic behavior of firms rather than provide a detailed evaluation of different ways to finance the subsidy, we merely summarize here the main ways in which taxation may affect the firms' strategies.

Suppose that there is a revenue tax in the U market. First, concentrate on competition between the two insiders. Since U market profit (through revenues) is subject to taxation, for the firm that operates in both markets, it becomes more profitable at the margin to decrease supply in the U market. In other words, a revenue tax makes it more attractive for the firm to sacrifice its U market profit in order to decrease its loss in the R market and thus tends to further increase prices. Second, when firms determine their bids they realize that, at the margin, a higher bid implies that a higher tax rate will need to be imposed on the U market to finance the subsidy. Thus, the U market insiders have an incentive to submit a lower bid than otherwise. Furthermore, an outsider may want to submit a higher bid since increasing the tax rate only affects firms active in the U market. Thus,

[19] For a discussion of the effect of price regulation on a firm's quality offerings in oligopolistic markets, see Vander Weide and Zalkind (1981).

TAW_R_COCDR1#80Attachment
Page 485 of 739

the fact that the tax rate is determined so that it finances the required subsidy may make the insiders willing to bid for a lower subsidy than otherwise, and introduces an additional difference between the strategic positions of insiders and outsiders.

The ideas presented here and our analysis are relevant for a number of markets. Deregulation and privatization policies, which typically involve some form of bidding procedure for entry, have been enacted in a number of countries and allow firms to enter and compete in profitable segments of an increasing number of markets. These policies often coexist with a concern of governments that service and supply must also be provided to less profitable segments of these markets. In this paper we have identified how such an environment can alter the strategic positions of inside and outside firms and assessed the implications for market competition and entry.

THE BOND SCHEDULING PROBLEM OF THE MULTI-SUBSIDIARY HOLDING COMPANY*

KENNETH R. BAKER† AND JAMES H. VANDER WEIDE‡

This paper presents a decision-theoretic model of the bond scheduling problem faced by a multi-subsidiary holding company such as AT&T or GTE. The objective is to minimize the total cost of bond flotations across all subsidiaries, where total cost is the sum of the yield paid to investors, the flotation expense associated with the preparation of each issue and the opportunity expense to each subsidiary of not meeting its request at the desired time. Our model suggests that the timing of bond issues is primarily a problem in trading off the diseconomies of issuing many bonds in one month with the penalty costs of delay. An efficient dynamic programming algorithm for solving the problem is also presented along with an example.
(CORPORATE FINANCE, FINANCE-MANAGEMENT)

1. Introduction

Multi-subsidiary holding companies annually acquire billions of dollars from the U. S. bond markets. During recent years American Telephone and Telegraph and General Telephone and Electronics have together accounted for about twelve to fifteen percent of the total funds raised in these markets. When the holding company's subsidiaries process their bond offerings through the headquarters and the total cost of obtaining funds depends on how many bonds are being processed jointly, a bond scheduling problem exists. In this paper we model this problem and solve it with the aid of a dynamic programming recursion.

That bond scheduling problems are similar to those appearing in the theoretical inventory literature was first noted by Bierman and McAdams [1] and Bierman [2]. Recently, Litzenberger and Rutenberg [7] extended the work of Bierman and McAdams to capture more of the stochastic, dynamic environment of this problem. These authors essentially drew on the analogy with single-product inventory models in order to structure the bond scheduling problem for a single firm. The model presented here is also based on inventory theoretic concepts, but it differs from previous work in that it accounts for the interdependencies introduced by the multi-firm character of many realistic bond scheduling problems.

The next section of the paper contains a brief justification for the underlying premise that the maturity structure of the firm's debt matters. §3 contains a verbal description of the multi-subsidiary holding company's bond scheduling problem. The problem is modelled as a mathematical programming problem in §4 and solved with the aid of a dynamic programming recursion. A discussion of possible extensions to the model is contained in §5.

2. Optimal Maturity Structure of the Firm's Debt

The bond scheduling model described in the later sections of this paper rests on the underlying premise that there exists an optimal maturity structure for the firm's debt. The finance literature offers two theoretical justifications for this premise. One justifi-

cation stems from the work of Lintner [5] and [6] and Rubinstein [9] on the theory of segmented markets, another stems from the work of Jensen and Meckling [4] on the agency costs embodied in financial decisions. In this section, we discuss these important theories and suggest how they can be extended to consider the optimal maturity structure of the firm's debt.

It is well established (see Modigliani and Miller [8]) that the value of the firm is invariant to capital structure decisions when capital markets are perfect. To explain the observed cross-sectional regularity in capital structures, therefore, we must introduce imperfections such as transactions costs, information costs or bankruptcy costs into our analysis. Lintner and Rubinstein introduce these imperfections through the device of segmented markets, where by "segmented markets" they mean that some investors or firms are restrained from investing or borrowing in at least some markets.

Assume (following Rubinstein) that capital markets are partially segmented in the sense that the set of individuals who buy the firm's stock is disjoint from the set of individuals who buy the firm's bonds. Furthermore, assume that debt is risky, that the firm's future equity value is taxed at the rate τ and that all investors seek to maximize the expected value of the utility of end-of-period wealth, where either utility can be expressed as a quadratic function of wealth or end-of-period wealth is normally distributed.

Then, as shown in Rubinstein [9, p. 756], the present value of the firm is given by the expression:

$$V = V^* + B\left[\tau - \frac{(1-\tau)\mathrm{Cov}(\tilde{R}_f, \tilde{W}_m)}{\tilde{R}_f}(\gamma_2 - \gamma_1)\right]$$

where V^* is the present value of an all equity financed firm, B is the present value of the firm's risky debt securities, $\tilde{R}_f$ is one plus the rate of interest on the firm's debt, $\tilde{W}_m = \tilde{W}_{m1} = \tilde{W}_{m2}$ is the end-of-period market value of all other securities in the equity and debt markets and γ_1 and γ_2 are the market price of risk in the equity and debt markets, respectively. This function has an interior maximum with respect to the level of the firm's debt when $\tau > 0$, $\mathrm{Cov}(\tilde{R}_f \tilde{W}_m) > 0$ and $\gamma_2 > \gamma_1$. Other sets of assumptions for which the firm's value function has an interior maximum are discussed in Lintner [6].

To extend the segmented markets theory to the case where the firm can issue two kinds of debt, one "short" and one "long" perhaps, we need merely assume that the firm sells securities in three partially segmented markets rather than two. The expression for the firm's market value is more complex in this case, but it can be shown that under similar conditions to those stated above, the firm's value function has an interior maximum with respect to both kinds of debt instruments. Thus, under these conditions there exists an optimal maturity structure to the firm's debt.

Jensen and Meckling [4] provide an alternative explanation for the existence of an optimal capital structure. Suppose that the firm's stock is held exclusively by a single individual owner/manager and that the firm currently has some debt in its capital structure as well. Jensen and Meckling note that the individual owner/manager can expropriate the wealth of the current bondholders by either accepting projects of greater risk than the bondholders thought at the time they purchased the bonds or by issuing additional bonds and using the proceeds to retire some of the firm's stock. On the other hand, if the single owner/manager decides to issue additional stock to outsiders, he can also expropriate some of their wealth by spending money on perquisites for himself and sharing the cost with the other owners. The bondholders and new shareholders can protect themselves from raids on their wealth only by incurring monitoring, or agency, costs that increase with additions to debt and equity,

TAW_R_COCDR1#80Attachment
Page 490 of 739

respectively. Since agency costs are a net drain on the system, it will be in everyone's best interest for the firm to adopt a capital structure that minimizes these costs. Under Jensen and Meckling's assumptions, this will occur at some point where the firm has both debt and equity in its capital structure.

The Jensen-Meckling arguments can also be extended to the case where the firm issues both short- and long-term debt. Because of the relatively large transactions costs of issuing long-term debt (associated with SEC registration, preparation and printing of prospectuses, etc.), it is usually in the firm's best interests to finance short-term increases in receivables and inventories with short-term debt. (Securities with less than a nine-month maturity do not have to be registered with the SEC). Excessive use of short-term debt (i.e., short-term debt that is used to finance permanent cash requirements), however, can lead to a significant increase in the probability of bankruptcy, due mainly to the possibility that the firm will not be able to roll over its short-term securities when they mature. At the same time, the increase in the probability of bankruptcy makes the short-term debtholders particularly vulnerable to raids on their wealth of the type mentioned above. If they have to incur agency costs to prevent such raids, the firm can maximize its value by choosing a capital structure consisting of both short- and long-term debt in addition to equity.

3. Problem Description

The bond scheduling problem of the multi-subsidiary holding company can be described as follows. The company headquarters periodically receives from each subsidiary a cash flow forecast for the next 12 to 18 months. The forecast includes, among other things, a demand for one or more bond issues. When the headquarters decides to float the bonds, it can expect to incur costs of several kinds. One rather obvious cost is the yield which the firm must pay investors to induce them to lend their money. The yield cost may depend not only on when the bonds are issued, but also on how many are issued at one time. A second cost is the flotation expense associated with the preparation of each issue. Since some of the preparatory functions require specialized skills, these costs usually increase with the number of issues that are handled jointly. A final, and often overlooked, cost is the opportunity expense to the subsidiary of not meeting its request at the desired time. This cost is measured by the difference between the rate the firm pays for additional short-term borrowing and the yield which it pays on the bond. (We assume for convenience that a firm requests a new bond for the point in time when its short-term debt reaches its optimal level.) The rate on short-term borrowings should include both the cost of compensating balance requirements and the impact of operating and legal restrictions on the firm's liquidity that are imposed to avoid the agency costs mentioned in §2. It is these latter factors which cause the real short-term borrowing rate to exceed the long-term rate when the firm deviates significantly from the optimal maturity structure of its debt. In some cases there also may be limitations on the number of periods for which the subsidiary's request can be delayed. The holding company's problem then is to schedule the various subsidiary bond flotations so as to minimize the total cost to the company and at the same time satisfy all important financial constraints. To accomplish this minimization, the holding company must balance the diseconomies of bunching several issues in one period with the penalty costs of delay.

In order to formulate and solve the holding company's bond scheduling problem, each of the cost functions described above must be carefully specified. In addition, we find it convenient to make several simplifying assumptions. The implications of relaxing these assumptions will be discussed in §4.

TAW_R_COCDR1#80Attachment
Page 491 of 739

Cost Functions. Let $x_{it} = 1$ if a bond is issued for subsidiary i ($i = 1, \ldots, S$) in period t and $x_t = \sum_{i=1}^{S} x_{it}$ denote the total number of bonds issued in period t. Furthermore, let y_{it} denote the size of bond issued for subsidiary i in period t and $Y_t = \sum_{i=1}^{S} y_{it}$ the total number of dollars raised in t. The preparation cost in period t depends on both the number and total size of the issues and is written most generally as $f_1(X_t, Y_t) = g_1(X_t) + g_2(Y_t)$. The yield cost in period t depends on the total size of the issues and can be written $f_2(Y_t)$.

Although our solution algorithm does not depend on the shapes of these cost functions, it may be instructive to comment on the forms they would likely take. The component g_1 of preparation cost encompasses all fixed costs associated with a bond issue. We would expect that the fixed cost associated with a given bond would tend to increase with the number of bonds issued, due to the need for overtime work or the need to assign less experienced personnel to the task. The component g_2 of preparation cost encompasses all variable costs associated with a bond issue, including printing, commissions, and so on. Although some of these costs may depend on the bond size over certain intervals, they are generally not affected by the decisions open to the holding company. Thus the variable costs of preparation will not depend on the scheduling decision, and we shall therefore assume without loss of generality, the form of the preparation cost to be $f_1(X_t)$. The form of the yield cost function is more difficult to conjecture, but we would expect that yield costs begin to increase once a certain amount of funds are raised. Thus we expect that $f_2(Y_t)$ is likely to be convex.

The treasurer must recognize, when measuring $f_2(Y_t)$, that the firm's bonds will often mature in twenty-five, or more, years. The total cost of floating an excessive amount of money in one period is thus the present value, at the firm's opportunity cost of funds, of a twenty-five year incremental interest expense. This present value can be quite large, even though the incremental interest expense is relatively small.

When a subsidiary's bond issue is delayed, it must obtain funds temporarily from short-term sources. Let b_{it} denote the amount of short-term borrowings for subsidiary i in period t caused by any delay in its bond request and $B_t = \sum_{i=1}^{S} b_{it}$ the total such borrowing for all subsidiaries. The borrowing cost in period t depends on the total amount borrowed and is written $f_3(B_t)$. The form of f_3 is also difficult to conjecture, but we shall adopt a scenario in which the subsidiary requests a bond issue because it has made plans to invest substantially all of the funds raised in capital projects it has already approved. A delay in the bond issue forces the subsidiary to obtain these investment funds via short-term borrowing, and therefore we might represent the total borrowing cost as $f_3(B_t) = r\ B_t$, where r is the difference between the short-term and long-term borrowing rates.

We shall discuss in our concluding comments various ways of generalizing the basic model. The essential features of the cost structure, however, have been examined above. They are: (1) preparation costs that are increasingly expensive for a given bond as more bonds are scheduled in a given period, (2) yield costs that reflect increasing rates as the total amount of a period's bond issue increases, and (3) borrowing costs that penalize headquarters for scheduling a delay in meeting any individual subsidiary's request.

EXAMPLE. In order to help clarify the elements of the bond-scheduling problem, consider the simple example described in Table 1. In this example there are three subsidiaries requesting bond issues in the first month of a three-month horizon. There are actually 27 distinct feasible schedules for the three issues, assuming all requests must be satisfied by the end of the third month, and the table lists four of the possibilities.

The cost functions in the example are special cases of the general types discussed above. The preparation cost reflects an incremental fixed cost of $10,000 for the

TAW_R_COCDR1#80Attachment
Page 492 of 739

TABLE 1

	Month 1	Month 2	Month 3
Requests:	\$20 M from sub. 1 \$60 M from sub. 2 \$50 M from sub. 3	None	None

Cost Parameters:

Preparation Cost

Number of issues X	1	2	3
Cost $f_1(X)$	0	10K	25K

Long-term borrowing rate: 8% on total issues $\leq$ \$100M
8.1% on any excess over \$100M

Short-term borrowing rate: 10%

Possible Schedules:	Month 1	Month 2	Month 3
Schedule A	Sub. 2 (\$60M)	Sub. 3 (\$50M)	Sub. 1 (\$20M)
Schedule B	Subs. 2, 3 (\$110M)	Sub.1 (\$20M)	None
Schedule C	Subs. 1, 2 (\$80M)	Sub. 3 (\$50M)	None
Schedule D	Subs. 1, 2, 3 (\$130M)	None	None

second issue planned for a single month and \$15,000 for the third issue. The yield cost reflects a long-term borrowing rate of 8% for total issues in a month that do not exceed \$100 million, and an incremental yield penalty of 10 basis points on larger total issues. In other words, the incremental long-term rate is 8.1% on the excess issued over \$100 million. The short-term borrowing rate is 10%. For simplicity, we assume that these rates hold in each period of the planning horizon, and that the firm's cost of capital is stable at 8%. Also, we shall assume that all of the bonds will have 25-year maturities.

To focus on the essential elements in the trade off, note that there is no difference in the yield cost for any schedule unless there is a total issue above \$100 million somewhere in the schedule. Thus we can equivalently treat the incremental yield cost as zero if the total issue does not exceed \$100 million. Otherwise, the yield cost must reflect the premium on a large issue. For a total issue of Y, the incremental yield cost in our example applies to the amount $(Y - 100\text{M})$ and reflects the present value of annual interest payments of 0.1% over 25 years, discounted at the cost of capital. Thus

$$f_2(Y) = (0.001)\,(10.67)\,(Y - 100\text{M}) \quad \text{if } Y > 100\text{M},$$
$$= 0 \quad \text{otherwise}$$

where 10.67 represents the present value of a stream of annual \$1 payments over 25 years, discounted at 8%. Similarly, the incremental penalty cost for short-term borrowing is

$$f_3(B) = 0.02B$$

In Table 2 we show a cost breakdown by month for each of the four sample schedules. Schedule A represents a "spreading" strategy, in which the goal is to distribute the bond issues over time in order to avoid excess preparation cost and yield cost. Schedule D represents a "stacking" strategy in which the goal is to adhere to the timing requests of the subsidiaries and avoid all penalty cost due to delays. Schedules B and C represent intermediate combinations which allow for some spreading and some stacking. By focusing on the incremental costs in this problem, we see that there

TAW_R_COCDR1#80Attachment
Page 493 of 739

TABLE 2

	Month 1	Month 2	Month 3	Total Cost
Schedule A	\$60M	\$50M	\$20M	
Preparation	0	0	0	
Yield	0	0	0	150,000
Delay	116,667	33,333	0	
Schedule B	\$110M	\$20M	0	
Preparation	10,000	0	0	
Yield	106,700	0	0	140,033
Delay	33,333	0	0	
Schedule C	\$80M	\$50M	0	
Preparation	10,000	0	0	
Yield	0	0	0	93,333
Delay	83,333	0	0	
Schedule D	\$130M	0	0	
Preparation	25,000	0	0	
Yield	320,100	0	0	345,100
Delay	0	0	0	

are considerable differences among the various ways of making the spreading/stacking trade-off. In a larger problem, with many subsidiaries and a planning horizon of several months, the financial manager will not be well-equipped to make this trade-off optimally using an intuitive approach. A formal approach to the problem, on the other hand, can accommodate the complexities of the trade-off in large problems and still produce minimum-cost schedules.

3. Formulation and Solution Algorithm

Assumptions. In addition to the above specifications, we impose some further restrictions, partly as a means of simplifying the formulation, but largely to reflect policies currently followed in practice by firms facing this type of problem.

1. We require that no bond issue be delayed more than M months. In principle this assumption is equivalent to treating borrowing costs as if they become infinite after M months. In practice, however, such a constraint is often imposed in order to avoid the implicit cost due to "loss of good-will" associated with extended short-term borrowing. The solution method allows us to study, via sensitivity analysis, the impact of varying the delay limit M.

2. We assume that the minimum interval (in months) between requests from a given subsidiary exceeds $M + 1$. This assumption permits us to consider only schedules in which there is a separate issue for each request. This is not an unrealistic assumption, however, because firms do appear to be unwilling to "double-up" on the requests from a particular subsidiary.

3. We assume that bond issues will never be made for only a portion of a subsidiary's request. Here again, firms seem to find that the large fixed cost of preparation renders it undesirable to split a request into two issues.

As a result of these assumptions, we may conclude that the bond issue for subsidiary i (or the short-term borrowings induced by a delay) will always be equal to the size of the most recent request:

$$y_{it} = 0 \text{ or } d_{it} \text{ or } d_{i,t-1} \text{ or } \ldots \text{ or } d_{i,t-M}$$

$$b_{it} = 0 \text{ or } d_{it} \text{ or } d_{i,t-1} \text{ or } \ldots \text{ or } d_{i,t-M+1}.$$

TAW_R_COCDR1#80Attachment
Page 494 of 739

Formulation. Under the above assumptions, the holding company's bond scheduling problem can be described mathematically as follows

$$\text{Minimize } \sum_{t=1}^{T} \left[f_1(X_t) + f_2(Y_t) + f_3(B_t) \right]$$

$$\text{with respect to } x_{it}, y_{it}, b_{it}, \qquad 1 \leqslant i \leqslant S,\ 1 \leqslant t \leqslant T$$

$$\text{subject to } b_{it} - b_{i,t-1} + y_{it} = d_{it}, \qquad 1 \leqslant i \leqslant S,\ 1 \leqslant t \leqslant T,$$

$$d_{it} b_{i,t+M+1} = 0 \qquad 1 \leqslant i \leqslant S,\ 1 \leqslant t \leqslant T,$$

$$b_{it} \geqslant 0, y_{it} \geqslant 0, x_{it} = 0, 1,$$

where it may be assumed, without loss of generality, that $b_{i0} = b_{iT} = 0$.

Solution Algorithm. A straightforward attempt to build a dynamic programming recursion for our formulation could easily lead to the use of a state space with S dimensions. A major holding company may have around $S = 20$ subsidiaries and it may be interested in planning its bond issues over a horizon of up to $T = 18$ months. A multi-dimensional state space is definitely undesirable in this context, and we sought instead a one-dimensional state representation as a foundation for a more efficient recursion. Drawing on analogous work in multistate techniques for scheduling [3], we define the state variable as a set:

$J_t =$ the set of subsidiaries for which previous requests are still pending at the start of period t. Formally, this means $i \in J_t$ whenever $b_{i,t-1} > 0$.

Similarly, we define our decision variable as a set:

$I_t =$ the set of subsidiaries for which bonds are issued in period t. Formally, this means $i \in I_t$ whenever $y_{it} > 0$. Also, $b_{it} = 0$ if $i \in I_t$.

In addition we can utilize the information given in the problem to define:

$R_t =$ the set of subsidiaries requesting a bond issue in period t. Formally, this means $i \in R_t$ whenever $d_{it} > 0$.

With these definitions we may express the state transformation as:

$$J_{t+1} = J_t + R_t - I_t, \qquad 1 \leqslant t \leqslant T.$$

We can now develop a recursion for dynamic programming. Let

$G_t(J_t) =$ the minimum cost over periods $t, t+1, \ldots, T$, given that the subsidiaries in J_t have unfilled requests at the end of period $t-1$,

and

$C(I_t) =$ the costs incurred in period t as a result of issuing bonds in period t for the subsidiaries in I_t. The form of this function is $f_1(X_t) + f_2(Y_t) + f_3(B_t)$.

The recursion is:

$$G_t(J_t) = \min_{I_t} \{ C(I_t) + G_{t+1}(J_t + R_t - I_t) \} \tag{1}$$

where

(1) the problem is to determine $G_1(J_1)$, along with the associated schedule, for $J_1 = J_{T+1} = \emptyset$ and $G_{T+1}(\emptyset) = 0$.

TAW_R_COCDR1#80Attachment
Page 495 of 739

(2) $I_t \subseteq J_t \cup R_t$ and, in particular, $i \epsilon I_t$ if $i \epsilon J_t \cap R_{t-M}$

(3) $C(I_t)$ is defined as follows:

a) if $i \epsilon I_t$ then $x_{it} = 1$ and $X_t = \sum_{i=1}^{S} x_{it}$;

b) if $i \epsilon I_t$ then $y_{it} = \sum_{j=0}^{M} d_{i,t-j}$ and $Y_t = \sum_{i=1}^{S} y_{it}$;

c) if $i \epsilon J_t$ but $i \notin I_t$ then $b_{it} = \sum_{j=0}^{M-1} d_{i,t-j}$ and $B_t = \sum_{i=1}^{S} b_{it}$;

d) then $C(I_t) = f_1(X_t) + f_2(Y_t) + f_3(B_t)$.

As in the conventional dynamic programming approach [5], the calculations follow a backward recursion. First, calculations of $G_T(J)$ are made for all feasible subsets $J = J_T$. Then $G_{T-1}(J)$ are calculated, and so on, until finally $G_1(\emptyset)$ is determined. At each stage in the recursion it is necessary to record the subset I_t for which the minimum in (1) occurs, so that the optimal schedule can be reconstructed once the value of $G_1(\emptyset)$ has been computed.

The recursion requires that each feasible subset J_t be evaluated at each stage. Potentially, each subsidiary that has made a request in periods $t, t-1, \ldots, t-M$ could appear in this subset. If there are k such subsidiaries, then $G_t(J_t)$ must be evaluated for 2^k different subsets. An average value of k in large problems will be about $3M/2$, which means that it will often be necessary to evaluate several hundred subsets at a given stage, and several thousand in order to solve the problem.

To illustrate the dynamic programming calculations, we show in Table 3 the calculations necessary to determine an optimal schedule in the example problem of Table 1. Since there is no delay limit in this problem, the possible states J_t will be every possible subset in periods 2 and 3, while J_1 is empty. Thus there are 8 possible values of the state variable J_t for $t = 2$ and 3, and for each one the table lists the possible decisions $I_t \subseteq J_t + R_t = J_t$ and the "new" state J_{t+1} that results, one period later, from the state transformation. For each decision the resulting cost (in thousands) is represented as the sum of current preparation, yield, and delay costs plus optimal future cost. (The future cost has been omitted in stage $t = 3$ since $G_4(J) = 0$.) Following equation (1), the minimum of these sums is recorded as $G_t(J_t)$ and the corresponding decision starred. For period 1, we find the optimal decision to be $I_1 = \{1,2\}$ yielding $J_2 = \{3\}$. For period 2, when $J_2 = \{3\}$, we find the optimal decision to be $I_2 = \{3\}$ yielding $J_3 = \emptyset$. Thus the optimal schedule is to meet the requests of subsidiaries 1 and 2 in month 1 and the request of subsidiary 3 in month 2. The optimal total cost is $G_1(\emptyset) = 93.33$, corresponding to Schedule C evaluated in Table 2. The algorithm thus verifies that Schedule C is the optimal policy.

4. Discussion

In this section we describe variations of the formulation that are amenable to solution by the dynamic programming approach described earlier, along with more complicated extensions which remain topics for further research.

In the simplest versions of the model, all cost components (fixed costs, yields, and borrowing rates) are stationary. Perhaps the most useful generalization of this structure is to permit fluctuating yield costs and fluctuating interest rates on borrowed funds. Our model suggests that the timing of bond issues is primarily a problem in trading off the diseconomies of large issues with the penalty (borrowing) costs of delays. Nevertheless, in practice the problem is sometimes also viewed as one of exploiting favorable interest rate conditions in the funds market. Our model can capture such structure simply by allowing the cost component functions to be time-dependent, and replacing the composite cost function $C(I_t)$ in the recursion by $C_t(I_t)$. The dynamic programming calculations would not be significantly more difficult. Similarly, it is possible that subsidiaries have different credit arrangements and their borrowing rates might differ.

		{2, 3}	{1}	10 + 106.7 + 33.33 + 0
		{1, 2, 3}	Ø	25 + 320.1 + 0 + 0

We can adapt the model to this case by defining the borrowing cost function as

$$f_3(b_1, b_2, \ldots, b_S) = \sum_{i=1}^{S} r_i b_{it}.$$

A related generalization would be to a scenario in which interest rates fluctuate

TAW_R_COCDR1#80Attachment
Page 497 of 739

randomly. If we can assume at least that the differences between borrowing and yield rates would remain unchanged, we might model the behavior of interest rates with the help of Markov chains as for example in [6]. In this case, the minimization of expected cost can be attacked by dynamic programming, but the computational task is an order of magnitude greater. Another difficulty associated with applying such a model is the problem of obtaining reliable estimates for the many probabilities involved.

The subsidiary may not plan to use all the funds raised virtually at once but may instead foresee a continuing need for funds over time. Because of the fixed cost associated with an issue, a subsidiary would in this situation request more funds than it needed immediately. The funds obtained would then represent a decreasing surplus for some interval, in the spirit of Bierman's model [2]. If such a request were delayed by a decision at headquarters, the cost associated with such a delay would not be a penalty cost on the full amount of the issue (as our scenario implied above) but rather a penalty cost only on that amount that would have to be borrowed during the delay. In addition this penalty would be reduced by the savings in holding cost that would have been incurred on the funds surplus, had the issue been scheduled as requested. The complications created by this scenario can still be accommodated in our model, but the information requirements are more severe. The holding company could examine each subsidiary's request and corresponding forecasts for its need for funds over time. Headquarters could then determine the *effective* penalty cost rate, which could be expected to vary with time. The necessary changes in the model would be made in the borrowing cost function, which would be expressed most generally as

$$f_{3t}(b_1, b_2, \ldots, b_S) = \sum_{i=1}^{S} r_{it} b_i.$$

We reiterate, however, that this version of the model is more demanding in terms of information exchanged within the organization. In this case, the holding company would need to know not only the subsidiary's requests but also its cash flows (or, equivalently, its effective penalty rate on the amount of the request) over the interval that a delay could be considered.

We have assumed until now that the headquarters is concerned only with the timing of its subsidiaries' bond issues, and not with their relative size. We concentrated on this aspect of the problem because our conversations with financial managers who make this decision revealed that proper timing was indeed their primary concern. An obvious extension to our model would be to allow the headquarters to determine not only the timing of a subsidiary's bond issue, but the size as well. This extension, however, like the preceding one, would require a great deal more information from each subsidiary. In addition, though the enlarged problem is easy to formulate, it would strain most computational algorithms now available. We thus leave this aspect of the problem for future research.

RECENT DEVELOPMENTS IN MANAGEMENT SCIENCE IN BANKING*

KALMAN J. COHEN,† STEVEN F. MAIER† AND JAMES H. VANDER WEIDE†

Banking has been a fertile area for management science applications, as is evident from the review provided in this paper. The relevant management science models are discussed in terms of the areas of bank management for which they were intended. Under dynamic balance sheet management (i.e., internal bank financial planning) we consider forecasting techniques, simulation models and optimization models. Other areas of banking included are bond portfolio management, bank operations, corporate services, bank marketing and management of the loan portfolio. The authors provide an evaluation of the applicability of management science models in practice, discuss the extent to which some have been implemented and consider the philosophy of using management science models in banking.
(FINANCE; FINANCIAL INSTITUTIONS—BANKS)

1. Introduction

Management science models have been formulated to help executives with their planning, decision and control problems in a variety of banking areas. We have divided these efforts into the areas of bank management they were intended to address: dynamic balance sheet management, bond portfolio management, bank operations, corporate services, bank marketing and management of the loan portfolio. For the most part, our research in preparing this paper concentrated on reading and interpreting several hundred of the most recently published (in some cases new or unpublished) materials in the literature of management science in banking. In addition to the references cited in this paper, the interested reader should examine three books which contain numerous papers dealing with management science in banking: Cohen and Hammer [35], Eilon and Fowkes [52], and Cohen and Gibson [34].

In order to limit the scope of this present review paper and to avoid overlap with a recent review paper on the investments area (Cohen *et al.* [39]), we have explicitly avoided any discussion of applications of management science techniques to the management of trust department portfolios, which frequently contain large amounts of common stock. Furthermore, there are undoubtedly many worthwhile contributions which we have failed to cite in this paper, and this omission should not be construed as a negative judgment on their quality. Finally, although we frequently discuss implementations of management science models in specific banks, we have not conducted a survey to determine the number of banks that are using various techniques. Such surveys are reported in NABAC [91], Fabozzi and Trovato [55], McClure and Miller [85], and LaForge and Wood [73].

§2 of this paper discusses models and techniques useful to internal bank financial planning (which we prefer to call dynamic balance sheet management). First, in §2.A we discuss various techniques for forecasting relevant variables and parameters re-

quired for a bank to undertake its internal financial planning in a sound and orderly way. Then in §§2.B and 2.C we discuss both simulation and optimization models which have been used in dynamic balance sheet management. One specific aspect of dynamic balance sheet management which has received a considerable amount of modeling attention is bond portfolio management; this is discussed separately in §3. Various aspects of bank operations are considered in §4. Then in §5 we survey a variety of consulting services that banks provide for their customers, for which management science models have been formulated. §6 considers models and techniques which are helpful in the area of bank marketing, and §7 deals with models that have been applied to management of the bank's loan portfolio. This paper concludes in §8.

2. Dynamic Balance Sheet Management

Many different management science techniques have been used to help senior bank executives determine the size and composition of a bank's asset, liability and capital accounts over a multiperiod planning horizon. Sophisticated statistical techniques have been used to provide forecasts of deposits, loans and interest rates. Simulation and optimization models have been developed to help evaluate the economic trade-offs between important decision variables. In this section, we shall focus on some of the major thrusts that appear in the management science models for bank dynamic balance sheet management.

2.A. *Forecasting Models*

The choice of appropriate statistical techniques in bank forecasting models depends on the length of the forecast horizon. In the short run, it is reasonable to view the bank's loans and deposits as being determined primarily by environmental forces. If these forces act in a periodic fashion, then univariate time series models may provide excellent forecasts. In the long run, however, the bank may react to environmental disturbances by changing the desired composition of its balance sheet. Thus, it appears to be more appropriate in the long run to view variables such as loans and deposits as being determined simultaneously by both supply and demand factors. The financial sectors of large-scale econometric models are designed to capture these supply and demand forces, and hence they play a useful role in bank financial planning. In this section, we review several examples of both short- and long-run forecasting models.

Balzano [9] presents a good example of the application of univariate time series models to the forecasting of a daily variable—the bank's daily net clearing house liability. A good forecast of this variable allows the bank to maximize the return on excess balances at the Fed, or to minimize the cost of borrowing if it expects to be short of Federal Reserve balances. The Balzano paper provides a good discussion of problems that frequently occur in daily forecasting. These problems relate to the fact that while time series models are designed to discover data patterns that occur at equally spaced time intervals, economic variables such as check clearing patterns are often affected by factors such as holidays and day of the month that do not occur at fixed periodic intervals. Balzano describes how the time series model is adjusted to account for these irregularities.

Three papers by Cramer and Miller [44], [45], [46] discuss applications of univariate and multivariate time series models to forecasting weekly bank data. The first paper

TAW_R_COCDR1#80Attachment
Page 502 of 739

presents univariate time series models for the weekly average U.S. money supply (demand deposits plus currency), the weekly average demand deposits for a group of large New York City banks and the demand deposits at the end of each Wednesday of a small midwestern bank. The basic stages of time series model building are examined in detail in this paper, and the important relationships between forecasting and bank financial planning are explored. The univariate models provide good forecasts for each of these three data series. Although Cramer and Miller do not say whether or not their models have been used in practice, the potential value from their use is discussed.

The second and third Cramer-Miller papers explore the dynamic relationships between deposits, loans and interest rates, on the one hand, and bank balance sheet decision variables on the other. They demonstrate how the direction of causation flows from deposits and loans to interest rates, and finally to balance sheet decision variables such as bank investments. The multivariate time series models developed in these papers shed light on the appropriate dynamic specification of bank financial planning models.

Thomson [106] presents forecasting models for loans 30, 60 and 90 days ahead that are a useful link between the short-run models discussed above and the long-run econometric models discussed below. Although Thomson continues to treat loans as exogenously determined, he does allow for the influence of other exogenous variables such as the corporate need for short- and long-term funds and interest rates. Tests of Thomson's forecasting equations indicate that current loan levels, recent changes in loan levels, total lines of credit and firm commitments and the spread between prime and commercial paper rates are important determinants of future loans. The forecasting systems developed by Thomson have been used extensively in the planning process at Mellon Bank.

Long-run forecasting models recognize the fact that banks play a crucial role in the nation's financial system. A typical bank will often change the desired composition of its balance sheet in response to changes in Federal Reserve monetary policy. The bank's desired balance sheet composition interacts with the public's demand for bank balance sheet categories to determine the amounts actually in existence at any point in time. The financial sector of large-scale econometric models is designed to capture these interactions in the banking system. Although these models are aggregative in nature, they provide useful information, to be used along with information on economic factors affecting an individual bank, for the bank financial planner.

Boughton [15] contains a good discussion of the nature of econometric models and how they can be used in bank financial planning. His model contains 12 equations—a demand and supply equation for demand deposits, time deposits, currency, business loans and federal funds and demand equations for short- and long-term government securities. Boughton demonstrates how simulation experiments with the model can provide an appreciation for the effects of changes in monetary policy instruments. Many banks have developed similar econometric models for internal use, as well as for external consulting purposes.

2.B. *Simulation Models*

Computer simulation models seem to be the most widely implemented type of management science aid in bank dynamic balance sheet management. On the basis of personal communications, we believe that various types of simulation models are used in particular phases of dynamic balance sheet management at North Carolina Na-

TAW_R_COCDR1#80Attachment
Page 503 of 739

tional Bank, Northwest Bancorporation, Mellon Bank and Chase Manhattan Bank, and the published papers reviewed below report additional applications.

In their Annual Report [60], Great Western Financial Corporation briefly indicates that they have implemented a computer simulation model for their overall financial planning. They develop not only their best estimate forecasts for the coming month, quarter or year, but they also develop several plausible alternative scenarios. The simulation program provides them with a forecast of probable results for each different scenario. Since Great Western began updating these forecasts monthly, management has implemented its plans without major surprises.

Derwa [48] indicates how simulation-based financial planning models have been implemented at Societe Generale de Banque in Belgium, apparently with great success. The major simulation model is actually several submodels combined in one computer package. The relationships among key variables are diagrammed in this article to illustrate the extent of detail in the model. Derwa states that in his opinion psychological problems usually outweigh technical obstacles in applying any management science model, including simulation, to management problems.

Royer [100] has developed a simulation model which focuses on policy decisions of a bank and on forecasting net profit under various policy options. The model provides a scientific approach to evaluation of the consequences of policy decisions in a major Belgian bank, Banque de Bruxelles; it is being used in that bank's corporate planning department. Since Royer observes that there is resistance to change in a bank with deeply rooted traditions, he stresses that implementation of the model should proceed in a sound, orderly fashion, without undue impatience or haste.

One of the most extensive computerized simulation models developed for bank planning purposes is BANKMOD (see Robinson [99]). This has been developed at the Bank Administration Institute, but apparently it has experienced only limited use. Although this model has not been widely marketed, those banks which have used it have been reasonably pleased with it. BANKMOD is unique in that it addresses total bank financial planning. Its application could be relatively simple, since it has been made available to banks on a time sharing basis by the Bank Administration Institute.

2.C. *Mathematical Programming Models*

Although they are more difficult to formulate and more complicated for management to understand, mathematical programming models have distinct advantages over simulation models. Properly formulated mathematical programming models can determine the optimal size and composition of a bank's asset, liability and capital accounts over a multiperiod planning horizon, while simulation models only allow management to evaluate a small set of alternatives. Management inputs are primarily of two different types: (a) constraints on and policies concerning such variables as funds available for investment, acceptable risk levels, loan limits and regulatory requirements; and (b) forecasts of future interest rates, loan demand and deposit levels.

By far the most common type of mathematical programming model for dynamic balance sheet management involves (deterministic) intertemporal linear programming. The first reported application in dynamic balance sheet management was at Bankers Trust Co. from 1964 to 1969; see Cohen and Hammer [36], [37] and Cohen [33]. This LP model helps bank executives determine an optimal sequence of balance sheet positions for the bank over a multiperiod planning horizon which typically stretches several years into the future. This sequence of balance sheets is "optimal" in the sense

TAW_R_COCDR1#80Attachment
Page 504 of 739

that it results in the largest possible present value of the bank's net income, subject to a variety of constraints on the bank's risk, liquidity and other relevant considerations, and given the bank's initial balance sheet position and its economic forecast over the planning horizon. In practice at any point in time, such a model would not be run once with a single set of inputs to produce *the* optimal set of decisions. Rather, it would be used as part of a dialogue involving senior bank executives, technically trained management scientists, the LP model and a (partially computerized) data base; see Cohen [32].

Models of the general Cohen-Hammer type have been adapted for use in mutual savings banks and savings and loan associations by Serfaty [102] and for bank holding companies by Cohen and Lam [38]. A different approach to the use of deterministic linear programming over an extended time period is provided by Meyer zu Selhausen [88], whose model was developed in conjunction with a leading German bank. It consists of three interrelated and nested linear programming models, spanning time horizons of 90 days, one year and five years. Each of these three models include a full set of balance sheet variables, but the variables differ in their level of aggregation, being more detailed for the shorter horizon models. The objective function of the models is to maximize the contribution to bank profit from raising and investing funds, subject to constraints (which can also be considered as objectives of the bank) on the bank's liquidity, risk and other considerations. A rolling planning horizon is suggested, with the 90 day horizon submodel being updated at least monthly, the one year submodel being updated at least quarterly and the five year submodel being updated at least annually. Consistent with the approach suggested by Cohen [32], Meyer zu Selhausen says that his model should be used in a way that involves a computer dialogue between the planning system and the executives responsible for asset and liability management.

On the basis of personal contact, we know that both Mellon Bank and North Carolina National Bank are currently utilizing linear programming models as part of their dynamic balance sheet management process. Several savings banks in New York State and some savings and loan associations elsewhere have used an intertemporal linear programming model for their financial planning that was developed by Serfaty for the Savings Banks Association of New York State. Other LP models have been formulated by Chervany *et al.* [30] for the Northwestern National Bank of Minneapolis, Komar [70] for the Bank of New York, Robertson [98] for the Industrial National Bank of Rhode Island, Lifson and Blackmarr [78] and Fielitz and Loeffler [56] for unnamed banks, and Crane *et al.* [47] for the Federal Land Banks of the Farm Credit System.

There are two different approaches in the literature that explicitly incorporate multiple objectives into mathematical programming models for bank dynamic balance sheet management. One approach is goal programming, which recognizes the existence of multiple and possibly conflicting goals. Fortson and Dince [59] formulate a model concerned with four specific goals: profit, the ratio of loans to deposits, capital adequacy and liquidity. Their model is intertemporal, consisting of four quarters comprising a planning horizon of one year. This model apparently has been successfully implemented in a small national bank (less than $60 million in assets) located in north Georgia. The authors state that this country bank successfully used the model to investigate the cost of growth, and in the face of a liquidity crisis to develop alternative strategies while options were still available.

TAW_R_COCDR1#80Attachment
Page 505 of 739

A different approach to incorporating multiple goals into a mathematical programming model has been taken by Eatman and Sealey [51]. Their example model includes three specific objectives: maximization of net after-tax profit, minimization of the capital adequacy ratio (the ratio of required to actual capital) and minimization of the ratio of risk assets to capital. Using an algorithm developed by Zeleny [108] all nondominated extreme point solutions to the model are found (these are analogous to efficient frontier solutions). A nondominated solution is one where no objective function value can be improved upon without harming one or more of the other objective function values. Management is provided with a detailed report showing for each nondominated extreme point solution: (a) the objective function value for each of the multiple objectives, and (b) the detailed values of the corresponding decision variables. The executives must then consider the various possible solutions, to decide which solution best fits their multiple objective.

The most commonly suggested approach for incorporating uncertainty into mathematical programming models has been multistage stochastic programming with recourse (which is a generalization of two-stage programming under uncertainty); see Cohen and Thore [40], Booth [14] and Aghili *et al.* [1]. It is informative to consider in some detail the approach and results of Aghili *et al.*, who said that they introduced their two-stage model into the budgeting process of a small midwestern bank. Their model consists of two discrete time periods. The first period is relatively short, and it is assumed that relevant economic events can be accurately forecasted for this first period. The second period of the model corresponds to the more uncertain portion of the planning horizon, and the authors assume three alternative economic scenarios which provide specific forecasts of loan demand, deposit levels and interest rates under average conditions, easy money and tight money. The authors always include definitional, accounting, legal and financial constraints. They sometimes (but not always) include constraints which reflect management policy decisions concerning loan level and composition, deposit mix, capital adequacy and a minimum earnings (or maximum loss) level. The objective function is to maximize the expected value of stockholder equity. The authors applied the model to actual 1972 data for a small midwestern bank, and they found that when management policy constraints were included, the model produced results very similar to the bank's actual balance sheet, but that the model produced entirely unrealistic results when management policy constraints were not included. Therefore, they conclude that the most important constraints in their formulation of the bank management problem are the so-called policy constraints. These not only deal with management's attitude toward risk, but they also capture the essence of very complicated dynamic feedback mechanisms that would be difficult to formulate and would lead to computational difficulties. The authors indicate that the model was successfully used by the bank during 1973. In particular, the economic scenario for tight money depicted quite accurately the actual conditions which developed.

A somewhat different approach to the use of multistage stochastic programming with recourse is adopted in Lane [74]. This paper presents a multiperiod mathematical programming model formulated for dealing with short-term money management in a British commercial bank. The model explicitly incorporates some of the uncertainties faced by the bank in this problem area. In particular, Lane deals with what can be regarded as strategic uncertainty rather than tactical uncertainty. Strategic uncertainties are those major uncertainties that arise and have persistent effects over several

TAW_R_COCDR1#80Attachment
Page 506 of 739

time periods. An example of strategic uncertainty is government policy, which either could be unchanged or which could be changed to any one of several alternative policies. Once a government policy is adopted sometime during the planning horizon, however, it is assumed that the policy remains in effect for the rest of the horizon. Thus, a set of forecasts is necessary, each contingent upon the occurrence of a particular government policy. Lane shows how this type of strategic uncertainty can readily be incorporated into a multiperiod linear programming model. When there are a relatively small number of alternative scenarios possible, the stochastic linear programming model is transformed into an equivalent but larger deterministic linear programming model.

Another approach to explicit incorporation of uncertainty into mathematical programming models for bank dynamic balance sheet management is chance-constrained programming. This was initially suggested more than one decade ago by Charnes and Littlechild [28] and Charnes and Thore [29]. Unfortunately, there have not been more recent papers of which we are aware describing applications of this technique to bank dynamic balance sheet management.

The one relatively new approach to explicit incorporation of uncertainty in a multiperiod mathematical programming model for bank dynamic balance sheet management has been advocated by Brodt [21], [22]. This is essentially an adaptation of the Markowitz [83] efficient frontier version of portfolio theory. An efficient dynamic balance sheet management plan is one which maximizes expected profits for a given amount of risk, or which minimizes the amount of risk for a given amount of expected profits. Brodt uses essentially the same decision criterion as was used by Markowitz, but with two differences. Markowitz used a one-period planning horizon, while Brodt uses a multiperiod planning horizon. Markowitz measured "risk" by variance, whereas Brodt measures "risk" by either semiabsolute deviation [22] or by mean absolute deviation [21]. In both of the papers, Brodt formulates the multiperiod bank dynamic balance sheet management mathematical programming problem as minimizing the risk measure (which is a nonlinear objective function) subject to the expected profit equaling some particular value (which is parametrically varied to generate the efficient frontier) and sets of intratemporal and intertemporal constraints. The particular intratemporal and intertemporal constraints formulated are appropriate to an American commercial bank in [22] and to a Canadian chartered bank in [21]. By introducing some additional variables and making appropriate substitutions, Brodt is able to transform the nonlinear programming problem into an equivalent linear programming problem. One essential assumption that Brodt must make for this transformation technique to result in a computationally feasible linear programming problem is that there is a finite (and reasonably small) number of possible economic scenarios applicable to each decision. Brodt states that the size and structure of his model are such that it can easily and inexpensively be solved with existing LP packages. Personal correspondence with Brodt has revealed that he is in the process of implementing his [21] model in a large Canadian chartered bank.

3. Bond Portfolio Management

The bond (or investment) portfolio is one of the asset items considered under bank dynamic balance sheet management, discussed in the previous section. In terms of the broad aspects of dynamic balance sheet management, the bond portfolio is generally

represented at a relatively high degree of aggregation. Overall dynamic balance sheet management models usually determine the total amount of funds contained in the investment portfolio, sometimes determine the composition of these funds in terms of broad categories of government securities, agency securities and municipal securities, and perhaps also determine the maturity structure of each of these categories of securities. In managing the investment portfolio, it is frequently desirable to deal with specific issues of securities. In order to do so, management science models specifically devoted to bond portfolio management have been formulated and sometimes implemented.

One type of management science model that is relevant to selecting specific bond issues utilizes multivariate statistical analysis to determine the quality of bonds. This can be helpful in deciding whether unrated municipal bonds are of suitable investment quality for banks. This is important to both banks and bank examiners, since the majority of municipal bond issues are not rated by the major rating services. Examples of such models are found in Carleton and Lerner [26] and Horton [65]. Carleton and Lerner use discriminant analysis in an attempt to predict Moody's municipal bond ratings. Their model is relatively successful in classifying bonds in rating categories above Ba, but it is less successful in correctly classifying those rated below Ba. Horton uses discriminant analysis to determine whether municipal bonds are or are not of investment quality. The equation recommended by Horton utilizes as independent variables the ratio of debt to assessed value, the log of the population, the tax collection rate, and an indication of whether the municipality belongs to a group of poorer or to a group of richer states. For both the original sample and the holdout sample, approximately 80% of all bonds were correctly classified.

Another relatively specialized type of management science model for bond portfolio management relates to the arbitrage activities of government bond dealers. Although the prices of all U.S. Government securities are affected by systematic movements of interest rates, each security is also subject to random price changes. When price differentials develop which appear to be abnormal or irrational, they may provide opportunities for profitable arbitrage. Kramer [71] formulates a management science framework for evaluating arbitrage opportunities. Generally, dealers have undertaken arbitrage transactions on the basis of intuition and past experience. Kramer's model offers a more systematic approach to the decisions involved in arbitrage. It has been successfully implemented in a large commercial bank that is a major dealer in U.S. Government securities. Kramer describes the benefits that this dealer-bank has obtained through the use of the arbitrage model.

McDavid and Bettes [86] describe a system for analyzing the term structure of the U.S. Government bond market that has been implemented at First National Bank of Chicago. Nonlinear regression analysis is used to fit a yield curve to data for a selected set of U.S. Government securities at any point in time. The computer model can also plot yield curves, analyze the residuals of the individual securities from the yield curve, and perform a breakeven analysis.

Carleton and Cooper [25] discuss a problem in estimating the term structure of interest rates that is largely ignored in previous studies, including that of McDavid and Bettes. They correctly note that bond yields are actually an artificial arithmetical construct that, like the internal rate of return concept in capital budgeting, may have no economic significance. Instead of yield to maturity, the bond portfolio manager should be interested in the set of reinvestment rates that the market is applying to cash

TAW_R_COCDR1#80Attachment
Page 508 of 739

flows realized at different points in time. Carleton and Cooper calculate these market reinvestment rates from the coefficients of a regression of bond price on coupon payments over time for a large set of U.S. Government and Federal Home Loan Bank Board securities. Their results indicate that market reinvestment rates often differ significantly from yields to maturity and that bond portfolio managers would be well advised to consider the advantages of market rates rather than yields.

Most of the management science literature relevant to investment portfolio management has discussed specific models intended either for determining which securities to buy and sell, or else for determining major policy decisions such as the optimal maturity mix of the investment portfolio. These are generally either simulation or mathematical programming models.

Bradley and Crane [18], [19] utilize Monte Carlo simulation techniques to investigate whether barbell portfolios (in which the portfolio consists of bonds concentrated in a few short-term and a few long-term maturities, with no bonds having medium-term maturities) or laddered portfolios (in which the bonds in the portfolio are evenly spaced from short term to some maximum maturity) are likely to perform better in practice. They carefully define several different barbell and laddered portfolio strategies; they use a Markov process to generate a sequence of yield curves; and they measure the performance of various portfolios in terms of mean portfolio return, which they also subdivide into its components of interest income and capital gains, and portfolio risk, which they measure both by the standard deviation of return and by the "maximum" loss position (defined so that the realized and unrealized losses on 98% of the trials were smaller than this "maximum" loss).

The results of the Bradley-Crane simulation are ambiguous. If a bank were to manage its investment portfolio in an absolutely mechanical way, then laddered portfolios appear to work relatively well, especially when the standard deviation of return is the risk measure. However, when the maximum capital loss is used as a measure of risk, then barbell portfolios seem to perform about as well as laddered portfolios. For banks that wish to manage their portfolios actively (rather than following mechanical trading rules), barbell portfolios offer significant advantages over laddered portfolios having about the same level of expected return; barbell portfolios provide more liquidity and flexibility, even though their total return may be more volatile.

Another simulation of portfolio management rules is presented by Pulliam [96]. He defines twelve different portfolio strategies and simulates their performance. Half of the portfolio strategies depend upon a risk adjustment factor that Pulliam defines as the percentage decrease in price that would result from adding the expected one month rise in yield (for the given maturity) to the current market yield of a particular bond. This is determined by what he believes is a stable historical relationship between changes in yield-to-maturity and time-to-maturity. He uses this relationship to quantify risk and order bonds according to their efficiency. The results of his simulation suggest that a strategy of ignoring overall portfolio structure, and instead buying efficient bonds or selling inefficient bonds (depending upon whether there is a net funds inflow to or a net funds outflow from the bond portfolio) seems to provide the possibility of superior long-run performance compared to more conventional portfolio management methods.

Computer simulation programs are also directly used as an aid in the ongoing management of bond portfolios. Marcial [82] describes the Bondsens analysis devel-

TAW_R_COCDR1#80Attachment
Page 509 of 739

oped by Gifford Fong Associates. Included among the fifty or more institutions which use Bondsens are such banks as Morgan Guaranty Trust Company, Citibank, Chase Manhattan Bank, Girard Bank, Marine Midland Bank and Indiana National Bank. In effect, Bondsens can be viewed as a user-oriented computerized sensitivity analysis. The user provides as inputs a listing of his current bond portfolio holdings, the current prices of each bond and one or more forecasts of future yield curves (which get translated into forecasts of future prices for each bond). The program then develops a variety of reports indicating the impact of each future yield curve on the portfolio's return and risk. The risk and return dimensions of future portfolio performance are decomposed into a number of relevant subsidiary factors. This information can be helpful to a bond portfolio manager in deciding which particular securities he should buy and sell. More specifically, he can determine for a given economic projection which securities provide the highest return, analyze the trade-off between coupon and maturity volatility, determine which securities have the greatest market risk, determine which securities will be most affected by call provisions under a changing set of future interest rates, determine whether a particular proposed bond swap really improves future return and analyze the extent to which changing quality spreads influence portfolio return.

Let us now consider some of the mathematical programming (optimization) models that have been developed for (bond) investment portfolio management. Hodges and Schaefer [64] formulate an intertemporal linear programming model in which the decision variables are the amounts of each bond purchased or sold. They assume that all bonds are free of default risk, not subject to call provisions, and pay their interest coupons and principal repayments at prespecified points in time. There are exogenously specified net cash flow constraints in each period of the planning horizon. The objective function is to find that bond portfolio which minimizes the cost of meeting all the constraints. The marginal tax rates of the investor are considered in this model, and the results of the model are likely to be most useful when the investor's marginal tax rate is different from the implied marginal tax rates that determine the equilibrium structure of bond market prices.

Another model utilizing intertemporal linear programming for bond portfolio management is Chiang [31]. The main novelty of this model is the choice of its objective function: to maximize the minimum amount of excess liquidity over the planning horizon (so that any potential illiquidity during one period is spread over the entire planning horizon). Decision variables are the amounts of each security purchased and sold in each period. Exogenous net cash flows to the portfolio are specified and used in defining cash balance constraints. Standard inventory balance constraints are imposed. There also is a constraint specifying that at least some minimum level of profitability be obtained. While this is a deterministic linear programming model, the author interprets it as being useful to find that portfolio management policy providing the largest possible safety stock to meet unexpected future demands. The author uses the structure of the model to derive conditions under which single maturity and barbell investment policies are optimal. He finds that the optimal solution to his model is relatively insensitive to future interest rates.

One approach to incorporating uncertainty into an investment portfolio model is the use of dynamic programming under uncertainty, as discussed in Bradley and Crane [17], [19]. Rather than use conventional dynamic programming solution techniques, however, they develop a new algorithm utilizing mathematical programming decompo-

TAW_R_COCDR1#80Attachment
Page 510 of 739

sition combined with an efficient technique for solving subproblems of the overall portfolio model. Uncertainty is explicitly introduced in terms of the net funds flow into (or out of) the portfolio in each future time period, as well as the yield curve that will prevail in each future time. The authors state that this approach enables them to develop optimal solutions to bond portfolio problems which are sufficiently large to utilize all the information that managers can reasonably provide. Bradley and Crane conduct numerous computational experiments by varying the input data defining their model and examining the nature of the optimal portfolios which result. For a wide range of input parameters, they find that optimal portfolios tend to be laddered for both short-term and long-term maturities, but do not contain any intermediate maturity securities. Thus, the optimal portfolio is a compromise between the laddered and dumbell portfolio strategies that are frequently discussed in the literature.

A different approach to incorporating uncertainty in a model for bond portfolio management is to utilize the efficient frontier concept. One way of doing so is presented by Brodt [20]. This is a multiperiod linear programming model under uncertainty in which the decision variables are the various bonds to buy, sell and hold during each period of a multiperiod planning horizon. Each alternative economic scenario consists of a sequence of possible future interest rates and net cash flows into (or out of) the bond portfolio during each time period of the planning horizon; the probability of each scenario must be specified. The objective of this (nonlinear) programming problem is to minimize the semiabsolute deviation of possible portfolio profits. The constraints of the model include a constraint setting expected profit equal to a specified level (which is parametrically varied to trace out the efficient frontier).

Another approach to the use of efficient frontier analysis for bond portfolio management is Lane [75]. This describes a model that was developed and successfully implemented in the International Bank for Reconstruction and Development (part of the World Bank). The model is used to help manage a portfolio consisting of Treasury securities whose maturities range from one day to five years. There are typically between two hundred and three hundred eligible securities to purchase at any point in time. The major decision to be made is which maturities the funds should be concentrated in, and how the securities should be diversified between short and long maturities. It is necessary for the bond manager to forecast future market values of securities, and to estimate the extent to which the fluctuation in returns on each security are correlated with the fluctuations in returns on all other securities.

Forecasts of future security values are derived from a forecasted yield curve. Six different maturities (Federal funds, three month T-bills, six month T-bills, twelve month T-bills, two year notes and five year notes) are used to determine a yield curve, using a piece-wise-linear approximation. Forecasts of future yield curves are used to determine forecasts of future security prices. Holding period returns are computed for each of the six specified maturities and each forecasted yield curve. Probabilities of various future yield curves are specified. It is then possible to determine the expected returns vector and the variance-covariance matrix of returns, for each of the six specified maturity instruments. This provides the major inputs for an efficient frontier mathematical programming formulation of minimizing variance subject to meeting some specified expected return level (which is parametrically varied to generate the entire efficient frontier), constraints that the entire portfolio is invested, policy limitations on the maximum amount invested in any security or group of securities and nonnegativity restrictions to eliminate short sales. The efficient frontier is then gener-

TAW_R_COCDR1#80Attachment
Page 511 of 739

ated. The bond portfolio manager then utilizes his assessment of the bank's risk-return preferences in order to determine the optimal portfolio on the efficient frontier. This portfolio is interpreted as determining the areas of the maturity spectrum in which the bank should concentrate its purchases and sales. While the exact maturity proportions recommended by the model may not be entirely implemented, the analysis is useful in helping the portfolio manager decide which specific issues he should buy and sell.

Several recent papers explore an approach to managing bond portfolio risk that bypasses the need for complex probability information on future bond returns. The approach relies on a concept called "duration" that is first discussed in Macaulay [79] and Hicks [63]. Samuelson [101] and Fisher and Weil [57] show that, under certain assumptions about how forward interest rates change, it is possible to "immunize" a bond portfolio from interest rate risk by matching the average duration of the portfolio to the average duration of the liabilities that support the portfolio. Fisher and Weil present evidence that the strategy works to reduce risk significantly in practice, even though the assumptions do not hold exactly. Recent papers by Bierwag [12], [13], Cox *et al.* [43], and Cooper [41] discuss how immunization strategies may be formulated under several different assumptions about the way forward rates change. This line of research appears to offer significant promise for bond portfolio managers.

4. Bank Operations

The management of bank operations is undergoing a transformation; from a position of relative neglect, it is being increasingly recognized as a major element in the overall management of commercial banks. In this section we will examine three areas that have received particular attention in the management science literature. These are check processing, manpower planning and branch banking.

The area of check processing may be thought of as having at least three distinct components. First, the processing bank must arrange to collect items from its various branches on a timely basis. Because the flow of checks into the branch system occurs continuously throughout the business day, the bank must arrange a schedule of pickups that considers both the cost of the messenger pickup service and its impact on the availability (use of funds) the bank is able to obtain.

Svestka [105] describes a multiple traveling salesman algorithm combined with a series of other procedures including dynamic programming and regression to optimally determine the messenger pickup schedules for Cleveland Trust Co. He cites cost savings for the bank of more than a million dollars over a 5 year period and a float reduction of 30 million dollars because of better availability for transit checks (items drawn on out-of-area banks). The heart of the model is its capability to examine not only the volume of work and when it is generated, but also the kind of work. In particular, the analysis determines where the bulk of the large dollar transit items are coming from. For branches with large transit item output, the model arranges for exceptionally swift and frequent check pickup from the messenger crew.

Haas and Zoltners [61] have also developed a computerized bank check collection vehicle routing system. The model minimizes a cost function that includes factors for transportation costs, production costs and costs associated with missing availability deadlines. The method employed for finding a solution is a heuristic. The model has been tested using data from a number of banks and the authors report that they are currently in the process of implementing their model at one bank.

TAW_R_COCDR1#80Attachment
Page 512 of 739

A recent application in this area was communicated to the authors by Bank of America. They attempted first to use the Svestka [105] model, but found it had computational difficulties related to the structure of their data. Moreover, their application was somewhat unique because each branch received only one pick-up per day and the branches were individually responsible for the encoding and proofing of all their own checks. Using a heuristic solution method, they were able to reduce the total miles their couriers had to travel by 10 percent. The bank reported that their results were sufficiently encouraging that they were going to extend the project from just the city of San Francisco to other cities in the state of California.

The second stage in the check processing cycle is the sorting of checks into groups by the bank on which they are drawn. This is accomplished by high speed reader/sorter equipment. In most cases, the number of groups into which checks must be sorted far exceeds the capacity, called sort pockets, of the sorting equipment. Therefore, it is necessary to assign priorities in the form of a tree structure in order to sort the checks into the required groups. A paper by Murphy and Stohr [90] describes a dynamic programming application to this check sorting problem. The objective of their model is to determine a sort tree which minimizes sorting costs. (Sort costs are generally related to the number of times an item must be handled; therefore, the objective can be thought of as minimizing the average number of times an item is handled.) The model considers the issue of availability time only as a post-optimality question. The model was developed in conjunction with a number of Chicago banks.

The third stage within check processing relates to the determination of the means by which the checks are ultimately cleared. In practice, a bank may simply pass its checks to a local Federal Reserve Bank or Regional Check Processing Center (RCPC) for check processing, or it may direct-send some of its checks to correspondent banks or other remote Federal Reserve Bank branches for clearing. Large money center and regional banks traditionally have a fairly extensive direct-send program in order to improve availability. For example, one of the large Chicago banks sends on a daily basis to approximately 125 different points besides the Chicago Federal Reserve Bank. The only paper that we know of that has appeared that discusses this area of transit check clearing is by Hess [62]. However, he was primarily concerned with the problem from the viewpoint of the Federal Reserve System and in particular the establishment of an RCPC within the Third Federal Reserve District. The model was very comprehensive and so successful that it caused the Philadelphia Federal Reserve to establish its own operations research group and induced three other Federal Reserve Banks to do likewise.

The authors are currently working with North Carolina National Bank and First National Bank of Chicago in designing and implementing a transit check clearing model. The model's purpose is to select an appropriate set of transportation routes and clearing banks so as to obtain the optimal trade-off between improved check availability and cost. The model is an integer programming application of immense size. (One of the two applications has nearly 1 million integer variables.) With the use of some simplifying heuristics, the problem is, however, solvable in a reasonable amount of computer time.

The high degree of variability in the number of checks processed from day to day causes a special problem in the area of check processing. It is not unusual to find daily volumes varying by a factor of two for adjacent days. In order not to forego the opportunity cost associated with lost availability, the bank must schedule sufficient

TAW_R_COCDR1#80Attachment
Page 513 of 739

personnel to handle the highly variable workload. Boyd and Mabert [16] describe a two stage forecasting model used to predict daily check processing volume at Chemical Bank. The first stage in the model employs multivariate regression analysis. This permits adjustments for different days of the week, holidays, months, etc. Since regression residuals from this first stage were serially correlated, a second stage was added to the model that employed exponential smoothing based on forecast errors from prior periods to give the model a learning capability. The resulting model gave residuals that were uncorrelated with errors mostly in the 5 to 7 percent range.

Work force scheduling is the second major topic within the operations area we shall discuss. One may view this as either being a short-term problem in which scheduling of current employees is the only consideration or one may take a long-term staffing view. Moondra [89] considers the short-term problem of staffing for the money transfer department of Chase Manhattan Bank. The problem is of interest because of the marked peak in work load that occurs at about 1 p.m. New York time in money transfer operations. The formulation developed by Moondra is a linear programming model. Although the model would be more appropriately posed as an integer program, the author claims that the fractional results obtained from the linear program were, when rounded to integers, a good approximation.

In the area of long-term manpower planning, Jones *et al.* [67] describe an application for the National Westminster Bank of England. They cite five major factors in their manpower projection model which were demand, retirement, wastage (dismissal, resignation, death, etc.), promotion and recruitment. The model developed was of the simulation type and has been implemented both by the bank and other institutions in the U.K. and across Europe.

The final topic in this section deals with forecasting new branch bank locations. The success of new branches depends upon such factors as the market potential of the area it serves, share of the potential market actually tapped by the bank, total amount of the bank's deposits and its mix between demand and time deposits, the earnings yield realized and the expense ratio incurred by these deposits, the deposit growth rates that will materialize and the size of the initially required investment. The paper by Kramer [72] deals with projecting the deposit growth rate of potential branches. The characteristics used to determine the growth rate curve were the type of neighborhood served by the potential branch, the age of surrounding branches and the size of the branch to be established. The model was found to be superior to projections made by branch managers and the bank's branch location group. A second paper by Carter and Cohen [27] describes the use of risk analysis and simulation in determining the trade-off between the expected rate of return for a potential new branch and the risk involved in achieving the expected rate of return. It is a good illustration of the use of portfolio theory concepts in management science.

5. Bank Consulting Services

The area of bank consulting services can best be described as undergoing dramatic growth. Besides the routine consultation that comes with the lending activity, banks have recently become involved in many automated business services that are tied to the management of the working capital components of the balance sheet. Many banks now offer automated payroll, accounts payable, accounts receivable and inventory services. For a comprehensive overview of the area, see Beehler [10].

TAW_R_COCDR1#80Attachment
Page 514 of 739

One good example of the entry by banks into automated business services is inventory management. Based upon the generation of new sales orders and information on the receipt of inventory items, a bank's automated inventory system can generate purchase orders to replenish stock, accounts receivable customer information, on-line computer stock reporting, forecasts of inventory demand and a historical data base on demand cycles. It seems clear that banks in entering the market for automated business services are building on their expertise in management information systems gained from their own automation of check processing.

One of the first areas in which banks provided consulting services is cash management. In fact, many bank's consulting groups are still part of the cash management area. First National Bank of Chicago and Chemical Bank are two that fit this mold. Consulting in cash management is designed to help a corporation get better control of its float, i.e., funds that are in the process of collection or payment. The best-known management science problem in cash management is the lock-box location problem.

At the heart of the lock-box problem is collection float. Collection float is directly related to the distance between the customer and the corporation's processing center. In order to minimize such float, banks have developed a service by which they open the corporation's incoming payable envelopes and deposit the checks. If the bank is located close to the corporation's customers, this can significantly reduce collection float. This is the concept behind a lock box. (The name "lock box" refers to the post-office box to which the corporation's customers remit payments.) Lock-box processing was initiated in 1947 by Bankers Trust of New York and First National Bank of Chicago. The corporation that stimulated the development of the service is the Radio Corporation of America.

The first academic paper that was published on the lock-box problem was by Levy [77] in 1966. The paper proposed an algorithm for selecting the most appropriate cities in which to locate lock-box sites. The algorithm was a heuristic and of the so-called "greedy" class. Since this first paper, the literature on the lock-box location problem has grown to be one of the most voluminous in management science and has been split along two different paths. The distinction between these two approaches is traceable to the cost elements of the problem. Maier and Vander Weide [80] indicate that the variable and fixed cost components thought to be required for finding a solution are generally not available for the lock-box problem. They therefore substitute for the missing cost elements an additional constraint that limits the number of lock-box sites that could be selected by an algorithm. That is, instead of having fixed costs limit the number of lock boxes, they substitute an explicit constraint.

The distinction that now arises is that the formulation that includes this additional constraint has been shown to be NP-complete; see Cornuejols *et al.* [42]. That is, it has been shown that a running time bound that is polynomial in the parameters of the problem exists if and only if virtually all combinatorial optimization problems, including the traveling salesman problem, can be solved in polynomial time. Thus, it is very unlikely that an efficient algorithm exists.

Without this additional capacity constraint, a number of individuals have proposed very efficient branch-and-bound algorithms to obtain solutions. Basically, this is because the problem is structurally almost identical to the simple or uncapacitated plant/warehouse location problem. For a complete bibliography, see Cornuejols *et al.* [42]. On the other hand, for the problem with the constraint most approaches have been of the heuristic variety, either utilizing a greedy-type algorithm or an interchange

TAW_R_COCDR1#80Attachment
Page 515 of 739

heuristic. The interchange heuristic is the most used algorithm in practice, with the anthors knowing of over twenty banks using this method, including Citibank, Crocker Bank, First National Bank of Chicago, First National Bank of St. Louis, Girard Bank, Marine Midland Bank and Wachovia Bank and Trust.

One paper by Mavrides [84] used Lagrangian relaxation to solve the lock-box problem with the capacity constraint. With the use of the Khumawala [69] branch-and-bound code, Mavrides obtained surprisingly good results with Lagrangian relaxation. The author reports that for the large number of problems solved by Morgan Guaranty Trust, only in one case has the relaxation failed. It is interesting to note the dichotomy here between theory and practice. The Lagrangian relaxation method appears to make possible very good solutions, although the problem is NP-complete.

In practice, most banks are not concerned with the distinction between an exact algorithm, be it represented by branch-and-bound or the Lagrangian relaxation with a branch-and-bound subroutine, or a heuristic. The reason is that the heuristics, and in particular the exchange heuristic, are extremely accurate. Most banks today utilize an advanced form of the exchange heuristic (see Baker *et al.* [8]). In discussions with more than twenty banks representing many hundreds of actual case studies, no bank that utilizes this method has ever found that the algorithm failed to obtain a solution at least as good as that found by any other method. One advantage often cited for the exchange heuristic is its dependability. The heuristic's speed is independent of data, very fast, and highly predictable. Given that the basic problem is NP-complete, these are important characteristics.

A problem closely related to the lock-box problem is called the "corporate payment problem" or else the "disbursement location problem." A description of this problem was first given by Shanker and Zoltners [103]. This problem is the opposite of the collection problem in which a corporation attempts to minimize float. In the corporate payment problem the corporation tries to extend the period from the time one of its vendors deposits a check until the funds are deducted from the corporation's account. A more complete statement of the problem may also take into account mailing time with the intent here to extend mail time float. (This would be based upon the conception that an account is considered paid when the payment is postmarked and not when it is received.) In practice, models do exist to examine both the corporate payment problem based on purely disbursement float and also to include the mail float component. The methodology used to solve this problem is identical to that for the lock-box problem.

The lock-box and corporate payment problems are components of a larger problem dealing with the design of the corporation's complete banking system. For a corporation the selection of the banks with which it deals can affect not just collection and disbursement times, but also credit and non-credit services. Probably the first attempt at formulating this unified model was by Calman [24]. This work was later extended in a paper by Pogue *et al.* [94]. The basic approach used by both these papers is linear programming. As such, the models were only designed to allocate banking activity within an existing set of bank relationships. These models also provide an insight into the bank practice called double counting of balances. This technique permits a corporation to utilize its demand account balances both as part of a contractual obligation associated with a line of credit and to compensate the bank for services performed including the lock-box collection service; its implications for the effective cost of bank loans are analyzed by Stone [104].

TAW_R_COCDR1#80Attachment
Page 516 of 739

Another variation on the Calman model was developed by Maier and Vander Weide [81]. This paper differs from earlier work in that it simultaneously locates new lock-box and disbursement activities, as opposed only to allocating activities within a firm's existing bank system. This model has been implemented by First National Bank of Chicago, Girard Bank and First National Bank of Maryland.

6. Bank Marketing

Management science techniques have been applied in bank marketing to the analysis of market segments, bank image, the effects of advertising on the demand for deposits and loans and the characteristics of users/nonusers of bank services. The following review of management science applications is not intended to be exhaustive; it merely attempts to capture the flavor of the many contributions of management science to bank marketing.

If significant motivational differences exist between customer groups, banks can increase their marketing effectiveness by designing messages that have special appeal to each group. Robertson and Bellenger [97] demonstrate how statistical analyses of responses to customer questionnaires can help to identify distinct bank market segments. The data for their study were obtained from a mail survey of residents from three areas in a Rocky Mountain state. Factor analysis was applied in the first step of their study to determine the principal factors the bank customers thought to be important in their banking relationship. Cluster analysis was used in the second step to identify respondents who held similar views on the important factors. A profile analysis of the members of each cluster revealed distinct profiles for at least two of the customer clusters. Cluster I represented a group of highly educated, high income professionals who tended to stress the importance of integrity, ego enhancement and expertise in their banking relationship. Cluster VI represented a group of older, blue-collar workers for whom bank location was the most important factor. Although Robertson and Bellenger do not state whether their results had a practical impact, it is certainly conceivable that the banks in this state could use the results of this study to improve their marketing strategies.

As part of their market research, banks have spent a considerable amount of money on attempts to measure their banks' customer image. Customers are typically questioned on their feelings about various attributes of a particular bank and the data are analyzed to see whether significant differences exist. (See Ford [58] and Brown *et al.* [23] for examples of this approach.) Durand *et al.* [50] have recently tested an improvement on the traditional method, the adequacy-importance model of Wilkie and Pessemier [107], that allows for the importance that a customer attaches to each attribute in the bank selection decision. They find that the adequacy-importance model provides a reasonably efficient prediction of a customer's bank preference.

Bank marketing specialists are also concerned with the effect of advertising on the bank's ability to attract deposits and loans. Hughes [66] employs regression analysis to identify the variables that serve as predictors of deposits and loans for three savings banks in Boston. Since the bank's objectives are unknown, he estimates regression models with the dependent variable expressed as dollar volume of deposits and loans, number of accounts and market share of each. The savings deposit and loan dependent variables are explained in terms of controllable variables such as dividend rates, loan rates and advertising, and uncontrollable variables such as effective buying

TAW_R_COCDR1#80Attachment
Page 517 of 739

income per household, common stock dividend rates and earnings rates. The advertising variable has a positive long-run effect for two of the banks, but not for the third. Advertising seems to have very little effect on deposits and loans in the short run.

A bank's ability to market and promote new products can often be enhanced by knowledge of the economic and demographic characteristics of the customer group that is most likely to use the product. The papers by Awh and Waters [7] and Pool [95] employ discriminant analysis to identify the characteristics of users and nonusers of bank charge cards and cash dispensing machines, respectively. Both find the user and nonuser groups to vary significantly in terms of economic and demographic characteristics. The users of both products tend to be young and well educated, and have a higher average income than nonusers. Whether or not these results can be generalized to other markets and products is not clear at this time.

7. Management of Bank Loans

Management science contributions to the management of bank loans fall into two broad categories. The first category consists of papers that examine the lender's optimal credit granting and collection decisions. When the lender grants credit to a new applicant, he improves his knowledge of the probability that future loans will be paid back. If this knowledge has sufficient value in terms of expected future revenues, the lender may be willing to grant some loans that have an expected loss in the first decision period. The dynamic nature of the credit-granting decision makes dynamic programming a useful technique for its analysis. The optimal collection policy decision involves a trade-off between the increased expected payments over time from a more aggressive collection policy and the added costs of this policy. Dynamic programming models have also been formulated for this aspect of loan policy. The papers by Bierman and Hausman [11], Dirickx and Wakeman [49] and Mehta [87] are good examples of contributions in this category.

The second category consists of papers that report results of attempts to discriminate between good and bad credit risks on the basis of certain objective characteristics of the applicant, usually with the use of discriminant analysis. The procedure for the application of discriminant analysis to this problem can be described as follows. The user gathers a sample of previous loan applicants that have proved to be good or bad credit risks. Discriminant analysis is applied to the economic profiles of these applicants to determine whether they can be correctly classified. The discriminating weights for the original sample are then applied to the economic profiles of a new applicant to form a credit score for this applicant. If the score is above a prespecified cut-off level, determined so as to minimize the expected costs of misclassification, the applicant is classified as a good credit risk. He is classified as a poor credit risk if the score falls below the cut-off level.

Recent applications of discriminant analysis to the loan classification problem are described in three papers by Altman and his colleagues [2], [4], [5], a paper by Apilado *et al.* [6], a paper by Lane [76] and two papers by Orgler [92], [93]. These applications differ primarily with respect to the type of loan they attempt to classify and the data base they analyze. Altman [2] and Altman *et al.* [4] study bankrupt and nonbankrupt U.S. corporations in the 1946–65 and 1969–75 periods, respectively; Altman *et al.* [5] study the loan repayment performance of firms in the cotton and wool textile sector of France between 1968 and 1971; Apilado *et al.* study repayment patterns of consumer credit accounts in a southwestern state for 1970–71; Lane studies personal bankrupt-

TAW_R_COCDR1#80Attachment
Page 518 of 739

cies in California in the 1964–66 period; and Orgler studies "good" and "bad" commercial loans taken from the files of bank examiners in several East Coast states. In addition, Altman [3] studies the loan recovery experiences of banks in an effort to measure the expected costs of misclassification. Some of the models described in these papers are currently used by banks as part of their loan granting decision process.

Recent legislation prohibiting discrimination in the granting of credit has made the careful use of credit-scoring models especially important. Two papers by Eisenbeis [53], [54] and a paper by Joy and Tollefson [68] point out that the data samples of previous studies frequently failed to satisfy the underlying assumptions of the discriminant model. The sensitivity of classification decisions to the discriminant model's assumptions has not been extensively analyzed at this time. The validity of credit-granting decisions based on the results of credit-scoring models must therefore be judged on a case-by-case basis.

8. Conclusion

This paper has reviewed management science applications in banking. The reader of this review should agree that banking has been a fruitful area for management science applications. Part of this success is due no doubt to the excellent training and educational background of many bank managers. However, a large share of the success of management science in banking is also due to the nature of the business itself. Banks deal in money, and money is a product that is not only easily quantified but is also easy to relate to a bank's objective, the maximization of returns to stockholders.

In looking toward the future of management science in banking, we see an environment that is both hospitable and ripe with opportunities. Banking as a business will be undergoing dramatic change in the next few years. For example, legislation is being discussed that would end interest rate ceilings on time deposits. (Interest-bearing demand deposit accounts have already been introduced.) Compensating balance agreements, the cornerstone of the bank-corporate relationship, are being replaced by fee arrangements. The increased internationalization of the world economy has caused an expansion in the services that banks offer in the international area. These changes have greatly increased the competitiveness of the industry, forcing banks to offer new services, improve technology and concentrate on the objective of profit maximization. These facts bode well for the future of management science in banking.[1]

[1]This paper was presented at the 24th International Meeting of TIMS in Honolulu, Hawaii, June 18–22, 1979. The authors wish to thank Mr. David H. Allen for his considerable assistance in helping them initially read and evaluate the literature on management science in banking.

Expectations Data and the Predictive Value of Interim Reporting: A Comment

LAWRENCE D. BROWN*, JOHN S. HUGHES†,
MICHAEL S. ROZEFF‡, AND JAMES H. VANDERWEIDE†

1. *Introduction*

In a recent article in this *Journal*, Abdel-khalik and Espejo [1978], hereafter AE, presented a test of the predictive content of interim earnings reports in order to ascertain whether analysts "use these signals in revising the predicted portion of annual earnings" [1978, p. 3]. AE maintained that the results of their test "provided strong evidence of the predictive power contained in each of the first three interim reports" [1978, p. 11]. Unfortunately, the test conducted by AE was incapable of discriminating between two contradictory hypotheses:

H_0: Security analysts do not use the information contained in interim earnings reports to revise the predicted (remaining) portion of the annual earnings number.

H_1: Security analysts use the information contained in interim earnings reports to revise the predicted portion of the annual earnings number.

In their paper, AE introduced three scenarios: *RP1* was equivalent to H_0, the null hypothesis; *RP2* and *RP3* were two versions of the alternative hypothesis, H_1; *RP2* (*RP3*) was the hypothesis that the predicted portion

* Associate Professor, State University of New York at Buffalo; †Associate Professor, Duke University; ‡ Associate Professor, University of Iowa. This paper is a synthesis of Brown and Rozeff [1978*a*] and VanderWeide and Hughes [1979]. Brown and Rozeff [1978*a*] was presented by Abdel-khalik at the 1978 Doctoral Consortium and contains the empirical results of this paper. VanderWeide and Hughes [1979] conducted the simulation analysis presented herein. [Accepted for publication June 1979.]

of the annual earnings number is revised in the same (opposite) direction as the most recent forecast error.

The flaw in the AE analysis originated not from their original adaptive expectations models, but from the theorized values they assigned to the coefficients of their reduced form cross-sectional regressions under the null hypothesis.[1] Indeed, their original adaptive expectations models can provide an alternative set of tests which we shall show are more suitable for the hypothesis which AE wished to test.

Section 2 explains intuitively why the test conducted by AE cannot be used to discriminate between H_0 and H_1. Section 3 presents the results of a simulation and an analytical analysis. Section 4 considers an alternative, more powerful test based on the original adaptive expectations models developed by AE. Section 5 concludes the comment.

2. *Abdel-khalik and Espejo's Test of Predictive Content*

AE attempted to assess the predictive power of interim earnings reports by testing the significance of the coefficients in the following regression:[2]

$$PE_y = \lambda_1(D_y^1) + \lambda_2(D_y^2) + \lambda_3(D_y^3) + e_y \tag{1}$$

where:

PE_y = the annual prediction error as measured by the difference between the actual earnings per share at the end of year y and the analyst's forecasts at the beginning of year y

D_y^q = the difference between the actual earnings per share observed in quarter q and the analyst's most recent forecast for quarter q

λ_q = an adjustment coefficient which indicates the extent to which the analyst revises the annual earnings forecast after observing the error in his earnings forecast for quarter q.

Finding each of the estimated regression coefficients (except the intercept) to be significantly different from zero, AE rejected H_0 in favor of H_1. The finding that the coefficients are significantly different from zero cannot, however, be used to reject H_0. To see why, consider a simple scenario. Suppose that analysts make annual and quarterly forecasts at the beginning of the year. Then upon receiving interim reports, they do not revise their forecasts of the remaining portion of the annual earnings

[1] Even if AE had properly specified their test, however, they would have obtained biased and inefficient parameter estimates since they tested a reduced form model rather than their original adaptive expectations models. This is illustrated in Section 4.

[2] Equation (1) is, in essence, the reduced form model of the original adaptive expectations equations developed by AE, their equation (2).

TAW_R_COCDR1#80Attachment
Page 526 of 739

number, but instead they revise their forecasts of the total annual earnings number when their interim forecasts are in error by substituting into their annual forecasts the known interim numbers in place of their earlier predicted values.[3] Undoubtedly, some firms will report higher earnings than analysts had forecast and some, lower. This, of course, will be true for both the annual and quarterly periods. Accordingly, we anticipate finding a significant cross-sectional association between annual forecast errors and quarterly forecast errors even when no revision of the remaining portion of the annual earnings number takes place. Indeed, in this simplified case, it can be shown (see Section 3 and the Appendix A) that $\lambda_1 = \lambda_2 = \lambda_3 = 1$.

Once we allow for analyst forecast revision of the remaining portion of the annual earnings when quarterly results appear, our conclusions are not fundamentally altered in any way. In particular, the λ's will be greater (less) than one if analysts revise their forecasts of the remaining portion of the annual earnings number in the same (opposite) direction as the most recent quarterly error. Hence, one cannot discriminate between H_0 and H_1 upon finding that the regression estimates of the λ's are other than zero, since the λ's will be identically equal to one if H_0 is true and significantly greater (smaller) than one if the *RP2* (*RP3*) version of H_1 is valid. The estimated λ's will equal zero only in the unusual case when no revision of the total annual earnings number conditional upon quarterly reports takes place. In order for this to happen, the revision of the remainder of the annual earnings number must be equal in magnitude and opposite in sign to the summed interim errors to date. In effect, analysts would maintain intact their earlier forecasts of the annual earnings number, regardless of the signals in the interim reports. By testing the λ's against zero instead of one, AE tested the wrong hypothesis. The finding that the λ's are insignificantly different from zero is evidence in favor of the *RP3* form of H_1, not evidence in favor of H_0, as AE maintained. Note, also, that since unbiased forecasts are sufficient to ensure a zero intercept, one cannot rely on the intercept term being insignificantly different from zero to distinguish between H_0 and H_1.

Finally, the anticipated dependency of annual forecast errors on quarterly forecast errors does not rely upon collinearity of quarterly forecast errors. Quarterly forecast errors could be completely independent of each other and still be significantly associated with annual forecast errors. Although it is possible for quarterly forecast errors (with or without revision) to be dependent, AE implicitly assumed independence and

[3] This is a necessary feature of *The Value Line Investment Survey*, the data base used by AE. Value Line analysts make both quarterly and annual forecasts. When interim reports of the year being predicted are available, the Value Line annual forecast equals the sum of the known interim numbers plus the forecasts of the remaining quarters of the year.

obtained very low partial correlation coefficient estimates.[4] We begin, then, by analyzing the independence case.

3. *Null Hypothesis of No Revision*

3.1 SIMULATION ANALYSIS

To support the claim that the AE findings are likely to arise when no forecast revisions of the remaining portion of the year are made, a simulation was performed. First, two sets of quarterly earnings-per-share numbers were randomly generated for each of forty-five hypothetical firms. One set was labeled actual and the other predicted.[5] Note that, by construction, all 360 numbers (forty-five firms, four quarters, two sets) have the same expected values. After the quarterly figures were summed to obtain annual amounts, a cross-sectional *OLS* regression was run with the annual difference between actual and forecasted earnings as the dependent variable, and the first three quarterly differences as the independent variables. The simulated numbers and the individual forecast errors are available upon request; the results of the *OLS* regression appear in table 1.

These results are similar to those reported by AE in that the estimated coefficients of all three forecast error variables are positive and significant (except for the intercept term), in spite of the fact that due to the nature of our simulation, we know in advance that no forecast revisions were made. The results are purely an artifact of the requirements that, under independence and no revision, the quarterly forecast errors must sum to the annual forecast error when the latter forecast is made prior to the receipt of any interim reports of the year being forecast. The result that the λ's are not identically equal to one is due to random error. Thus, any

[4] If analysts are rational, then they will take advantage of any ex-ante dependence in their forecast errors to improve their forecasts. Ex-ante dependence, therefore, assumes irrational forecasting (Box and Jenkins [1970, p. 129]), making the AE independence assumption quite palatable.

[5] Specifically, we employed three icosahedral dice to obtain values between 0.00 and 9.99 Each die has twice ten sides with pairs of sides marked from 0 through 9. The properties of such dice as random number generators are described by Gardner [1968].

TAW_R_COCDR1#80Attachment
Page 528 of 739

attempt to reject H_0 on the basis of the estimated parameter coefficients being nonzero is inappropriate.

It is evident what the results of the simulation should be. Analytically, the sampling rule can be expressed as:

$$PE_y = D_y^1 + D_y^2 + D_y^3 + D_y^4, \tag{2}$$

where D_y^q, $q = 1, 2, 3, 4$, are independently distributed random variables with zero expected values. This model differs from equation (1) in that D_y^4 has now been included and the model coefficients are no longer explicit. Since the quarterly forecast errors are independent by construction, it follows that the *OLS* regression estimates will be unbiased, or equivalently that the expected values of $\hat{\lambda}_q$, $q = 1, 2, 3$, will equal one and the expected value of the constant term will equal zero.[6]

3.2 FURTHER ANALYSIS

Additional insight into the defect in AE's test is gained by considering, in quarterly form, the adaptive expectations models (their equation (2)) which were used to derive our equation (1). Independence of the quarterly forecast errors is no longer assumed, and revision of quarterly forecasts is now allowable. We show that to discriminate between H_0 and H_1, the coefficients (λ's) must be tested against one when using equation (1).

AE's adaptive expectations equation (their equation (2)) may be written as:

$$\hat{A}_t \mid Q_{it} - \hat{A}_t \mid Q_{i-1,t} = \lambda_i (Q_{it} - \hat{Q}_{it} \mid Q_{i-1,t}) + e_{it}, \qquad i = 1, 2, 3 \tag{3}$$

where:

A_t = annual earnings per share of year t
$\hat{A}_t \mid \Phi_T$ = analysts' prediction of annual earnings per share of year t conditional upon information set Φ_T available at T
Q_{it} = reported earnings per share in quarter i of year t
$\hat{Q}_{it} \mid \Phi_T$ = analysts' prediction of earnings per share of quarter i of year t conditional upon information set Φ_T available at T
e_{it} = random disturbance in quarter i of year t.

In words, the annual earnings forecast revision in quarter i is a linear function of the (one-quarter-ahead) error made in forecasting quarter i's earnings. To clarify the potential hypothesis tests of λ_i, we express the

[6] See Johnston [1972, p. 169]. We also provide a simple, yet instructive, proof in Appendix A that should demonstrate the effect of the implicit additivity restriction on forecast errors under no revision.

TAW_R_COCDR1#80Attachment
Page 529 of 739

left-hand side of equation (3) in quarterly form:

$$(\hat{Q}_{1t} + \hat{Q}_{2t} + \hat{Q}_{3t} + \hat{Q}_{4t}) \mid Q_{1t} - (\hat{Q}_{1t} + \hat{Q}_{2t} + \hat{Q}_{3t} + \hat{Q}_{4t}) \mid Q_{0t} = \lambda_1(Q_{1t} - \hat{Q}_{1t} \mid Q_{0t}) + e_{1t}, \tag{4}$$

$$(\hat{Q}_{1t} + \hat{Q}_{2t} + \hat{Q}_{3t} + \hat{Q}_{4t}) \mid Q_{2t} - (\hat{Q}_{1t} + \hat{Q}_{2t} + \hat{Q}_{3t} + \hat{Q}_{4t}) \mid Q_{1t} = \lambda_2(Q_{2t} - \hat{Q}_{2t} \mid Q_{1t}) + e_{2t}, \tag{5}$$

$$(\hat{Q}_{1t} + \hat{Q}_{2t} + \hat{Q}_{3t} + \hat{Q}_{4t}) \mid Q_{3t} - (\hat{Q}_{1t} + \hat{Q}_{2t} + \hat{Q}_{3t} + \hat{Q}_{4t}) \mid Q_{2t} = \lambda_3(Q_{3t} - \hat{Q}_{3t} \mid Q_{2t}) + e_{3t}. \tag{6}$$

Revisions of the total annual earnings forecast are shown in equations (4) through (6). To test whether the annual forecasts are revised in response to quarterly errors, the appropriate tests are $\lambda_i = 0$, $i = 1, 2, 3$. Now, by making use of the fact that $\hat{Q}_{it} \mid Q_{it} = Q_{it}$ and rearranging, (4) through (6) can be written alternatively and equivalently as:

$$(\hat{Q}_{2t} + \hat{Q}_{3t} + \hat{Q}_{4t}) \mid Q_{1t} - (\hat{Q}_{2t} + \hat{Q}_{3t} + \hat{Q}_{4t}) \mid Q_{0t} = (\lambda_1 - 1)(Q_{1t} - \hat{Q}_{1t} \mid Q_{0t}) + e_{1t}, \tag{4'}$$

$$(\hat{Q}_{3t} + \hat{Q}_{4t}) \mid Q_{2t} - (\hat{Q}_{3t} + \hat{Q}_{4t}) \mid Q_{1t} = (\lambda_2 - 1)(Q_{2t} - \hat{Q}_{2t} \mid Q_{1t}) + e_{2t}, \tag{5'}$$

$$(\hat{Q}_{4t} \mid Q_{3t} - \hat{Q}_{4t} \mid Q_{2t}) = (\lambda_3 - 1)(Q_{3t} - \hat{Q}_{3t} \mid Q_{2t}) + e_{3t}. \tag{6'}$$

Revisions of the predicted (remaining) portion of the annual number are shown in (4′) through (6′). To test whether the predicted portions of annual earnings are revised in response to quarterly errors, the appropriate tests in (4′) through (6′) are $(\lambda_i = 1) = 0$, $i = 1, 2, 3$, or equivalently in (4) through (6), $\lambda_i = 1$, $i = 1, 2, 3$. Since AE combine (4) through (6) to obtain equation (1) above, then the coefficients in (1) should be tested against one, not zero, in order to achieve AE's repeated intent [1978, pp. 1–3, 7, 9] to determine "if analysts in fact use these quarterly deviations to revise the predicted portion of the annual number" [1978, p. 4].

3.3 COEFFICIENT VALUES AND REVISION BEHAVIOR

AE also attempt to use their regression results to make inferences about the nature of analysts' revisions. They distinguish three cases, labeled *RP1*, *RP2*, and *RP3*. In all three cases, analysts upon receipt of interim reports incorporate the realized quarterly number into their annual earnings forecast, and they observe the sign of the current quarter's forecast error, which is actual earnings minus expected earnings (see n. 3). Behavior differs in how analysts revise predictions of the remaining portion of annual earnings. Under *RP1*, no revision occurs. Under *RP2* (*RP3*), revision of the remainder of the year is in the same (opposite) direction as the sign of the forecast error.

TAW_R_COCDR1#80Attachment
Page 530 of 739

AE argue that under *RP1*, only λ_1 will be nonzero, and it will be positive. Since this is the no-revision case, the correct hypothesis would be that λ_1 equals one under *RP1*. Furthermore, *RP1* does not imply that future forecasting errors will not occur. Rather, when they do, no revision is made of remaining quarterly earnings of the year. Thus, λ_2 and λ_3 are also determinate under *RP1* with predicted values of one, so that under *RP1* and H_0, $\lambda_1 = \lambda_2 = \lambda_3 = 1$. Similarly, if the alternative hypothesis *RP2* (*RP3*) is valid, the appropriate null hypothesis is λ_i, $i = 1, 2, 3$, is greater (less) than one.

A test of equation (1) presents several econometric difficulties. As it stands, the equation represents a test of how the set of sequential quarterly forecast errors of analysts are related to their annual earnings forecast errors as of the start of the year. This regression, as can be seen in equations (4) through (6), contains spurious correlations.[7] A second drawback is that the fourth-quarter error is implicitly contained in the disturbance term.[8] This acts to bias estimates of the regression coefficients. Finally, although economic theory suggests that the quarterly forecast errors of analysts should be ex-ante independent, sampling variation will cause some ex-post dependence or collinearity. This sampling variation not only produces inefficient estimates but is a source of bias of unpredicted sign on the estimated coefficients.[9]

At this juncture, it is evident that equation (1) is seriously suspect as a vehicle for providing a meaningful test of analyst revision behavior. Whatever the merit of the theoretical analysis which precedes the reduced form model, it is likely that the model as a cross-sectional *OLS* regression will be defective for testing the revision behavior described by AE.

4. *Alternative Test of Forecast Revision*

AE's analysis provides another set of relations which are more useful for determining if analysts systematically revise their forecasts when interim earnings statements become available. Consider the regressions based on AE's equation (2), our equation (3):

$$FEPS_{q,y} - FEPS_{q-1,y} = \lambda_q(D_y{}^q) + u_{q,y} \qquad q = 1, 2, 3 \tag{7}$$

where:

$FEPS_{q,y}$ = the *forecasted* annual earnings per share made in quarter q for year y

[7] For example, in equation (4), $Q_{1t} - \hat{Q}_{1t} \mid Q_{0t}$ appears on both the left- and the right-hand sides.

[8] See Appendix A; what this would mean is that the term $E(x_4'x_4)$ would no longer equal zero. Other effects are that estimates will be imprecise, with large errors, and dependent on particular samples.

[9] The nature of the ex-post sample bias is shown analytically in Brown and Rozeff [1978*a*, pp. 3–4] and is demonstrated empirically in Section 4.

Panel B: (Regressions with equation (1))			
Constant	−0.14	−2.3	
λ_1	3.17	10.3	0.70
λ_2	1.31	1.7	
λ_3	1.68	3.4	

* With respect to the null hypothesis that the λ_q, $q = 1, 2, 3$, all equal zero and one in that order in panel A and equal one in panel B.

$u_{q,y}$ = a random error term with mean zero and constant variance.

Note that when no revision of the total annual earnings number conditional upon interim reports takes place (i.e., $FEPS_{q,y} = FEPS_{0,y}$ for all q), the estimated coefficients of quarterly forecast errors would be insignificantly different from zero. Conversely, if any of the estimates are significantly different from zero, then this is evidence that forecasts are revised on the basis of quarterly forecast errors, but perhaps only in the sense of *RP1*. To discriminate against *RP1* further, we next test to see if the coefficients (i.e., λ's) are significantly different from one. If they are, it is evidence that analysts revise future forecasts conditional upon realized quarterly numbers.

The regressions from (7) enjoy three distinct advantages over (1): (*i*) they do not contain spurious correlations; (*ii*) the use of just the most recent forecast error as the independent variable eliminates problems of multicollinearity and bias; and (*iii*) unlike equation (1), (7) allows us to discriminate between *RP1*, the hypothesis of no revision of future quarters, and "*RP0*," the hypothesis of no revision of the (total) annual number. The potential importance of ex-post bias and testing power is reflected in the empirical analysis that follows.

Using a sample of fifty Value Line firms and five years of quarterly forecasts for each, the regressions given by (7) were run and the results shown in panel A of table 2 were obtained.[10] Observe that the estimated coefficients in panel A are all significantly greater than one (t-values of

[10] See Brown and Rozeff [1978*b*] for further details on the sample selected. Sample size equals 243 due to missing observations. The sample period was 1972–76.

TAW_R_COCDR1#80Attachment
Page 532 of 739

11.2, 4.7, and 9.5), a finding that is consistent with the hypothesis that in all three quarters analysts do revise their forecasts of the predicted portion of annual earnings in a fashion consistent with the *RP2* version of the alternative hypothesis.

To complete the comparison with AE, we also tested their model (i.e., equation (1) above) on the same data and obtained the results shown in panel *B*. In testing the hypotheses that the λ's differ from one (rather than zero, as AE reported for their sample), we observe that only the first- and third-quarter forecast errors have significant coefficients (with lower *t*-values than in panel *A*); the second quarter does not.[11] What we conclude from this result, when compared to panel *A*, is that the finding of an insignificant coefficient for the second quarter is more likely to be caused by the econometric problems inherent in equation (1) and is not a reliable indication that the *RP2* version of H_1 is invalid.

Although these tests do appear to be more powerful than AE's in detecting revisions, we do not claim, as they do, that such revisions constitute improvements over the forecasts previously made. To examine forecast improvement we would need to specify an appropriate loss function over forecast errors plus an error metric and analyze forecast errors. This is outside the scope of this comment and hence is not pursued here. We should note, though, that neither we nor AE investigated forecast accuracy, a sine qua non for an investigation of forecast improvement.

5. *Concluding Remark*

We do not claim that analysts fail to revise their forecasts on the basis of interim earnings reports, nor do we maintain that Abdel-khalik and Espejo's findings are inconsistent with H_1. Rather, we take the position that (*i*) AE's findings, as they interpreted them, did not allow rejection of H_0, the hypothesis of no revision of remaining earnings, and (*ii*) even if the correct interpretation is given to the results of the AE test, there exists a more powerful test available than the one they elected to employ. In a larger sense, these kinds of problems are as subtle as they are serious. It is not sufficient to find empirical results consistent with a hypothesis motivated by one's prior theory. One must also consider whether these results could conceivably be obtained when alternatives to that hypothesis are true and whether the test to be employed is the most powerful one available.

[11] These findings are similar to AE's when the null hypothesis is restated in terms of the λ's being equal to one (i.e., the first- and third-quarter coefficients are significant, while the second-quarter coefficient is not).

TAW_R_COCDR1#80Attachment
Page 533 of 739

APPENDIX A

Proof of Expected Values of Regression Coefficients

We define our sampling rule under the null hypothesis, H_0, as follows:

$$Y = X_1 + X_2 + X_3 + X_4 \tag{A1}$$

where:

$$X_q = D_y{}^q,\ q = 1, 2, 3, 4$$

$$Y = PE_y, \quad \text{and}$$

the X_q, $q = 1, 2, 3, 4$, are independently distributed random variables with zero means.

Consider the following *OLS* regression to estimate the implicit coefficients of X_q, $q = 1, 2, 3$:

$$Y_i = \lambda_0 + \lambda_1 X_{1i} + \lambda_2 X_{2i} + \lambda_3 X_{3i} + U_i,\ i = 1, 2, \ldots, n. \tag{A2}$$

In matrix notation, and using deviation form, we can write (A2) as:

$$\underset{(n\times 1)}{y} = \underset{(n\times 3)}{x}\ \underset{(3\times 1)}{\lambda} + \underset{(n\times 1)}{u}\ . \tag{A3}$$

The *OLS* regression estimate using (A3) is:

$$\hat{\lambda} = (x'x)^{-1}x'\,y.$$

Substituting, from (A1) in matrix form, we obtain:

$$\hat{\lambda} = (x'\,x)^{-1}x'(xe + x_4)$$

where e is the unit vector. Since, by construction $E(x'\,x_4) = 0$, then:

$$E(\hat{\lambda}) = E[E(\hat{\lambda}\,|\,x)] = E[(x'\,x)^{-1}x'(xe)] = e.$$

Also, since (in the original notation):

$$\hat{\lambda}_0 = \bar{Y} - \hat{\lambda}_1\bar{X}_1 - \hat{\lambda}_2\bar{X}_2 - \hat{\lambda}_3\bar{X}_3$$

and given the zero means of our sampling rule, then:

$$\begin{aligned} E(\hat{\lambda}_0) = E[E(\hat{\lambda}_0\,|\,X)] \quad &= E[E(\bar{Y} - \hat{\lambda}_1\bar{X}_1 - \lambda_2\bar{X}_2 - \lambda_3\bar{X}_3\,|\,X)] \\ &= E[\bar{X}_1 + \bar{X}_2 + \bar{X}_3 + E(X_4\,|\,X) \\ &\quad \lambda_1\bar{X}_1 - \lambda_2\bar{X}_2 - \lambda_3\bar{X}_3] \\ &= E[E(X_4\,|\,X)] = E(0) = 0. \\ &\quad \text{Q.E.D.} \end{aligned}$$

Expectations Data and the Predictive Value of Interim Reporting: A Comment

LAWRENCE D. BROWN*, JOHN S. HUGHES†,
MICHAEL S. ROZEFF‡, AND JAMES H. VANDERWEIDE†

1. *Introduction*

In a recent article in this *Journal*, Abdel-khalik and Espejo [1978], hereafter AE, presented a test of the predictive content of interim earnings reports in order to ascertain whether analysts "use these signals in revising the predicted portion of annual earnings" [1978, p. 3]. AE maintained that the results of their test "provided strong evidence of the predictive power contained in each of the first three interim reports" [1978, p. 11]. Unfortunately, the test conducted by AE was incapable of discriminating between two contradictory hypotheses:

H_0: Security analysts do not use the information contained in interim earnings reports to revise the predicted (remaining) portion of the annual earnings number.

H_1: Security analysts use the information contained in interim earnings reports to revise the predicted portion of the annual earnings number.

In their paper, AE introduced three scenarios: *RP1* was equivalent to H_0, the null hypothesis; *RP2* and *RP3* were two versions of the alternative hypothesis, H_1; *RP2* (*RP3*) was the hypothesis that the predicted portion

TAW_R_COCDR1#80Attachment
Page 537 of 739

of the annual earnings number is revised in the same (opposite) direction as the most recent forecast error.

The flaw in the AE analysis originated not from their original adaptive expectations models, but from the theorized values they assigned to the coefficients of their reduced form cross-sectional regressions under the null hypothesis.[1] Indeed, their original adaptive expectations models can provide an alternative set of tests which we shall show are more suitable for the hypothesis which AE wished to test.

Section 2 explains intuitively why the test conducted by AE cannot be used to discriminate between H_0 and H_1. Section 3 presents the results of a simulation and an analytical analysis. Section 4 considers an alternative, more powerful test based on the original adaptive expectations models developed by AE. Section 5 concludes the comment.

2. *Abdel-khalik and Espejo's Test of Predictive Content*

AE attempted to assess the predictive power of interim earnings reports by testing the significance of the coefficients in the following regression:[2]

$$PE_y = \lambda_1(D_y^1) + \lambda_2(D_y^2) + \lambda_3(D_y^3) + e_y \tag{1}$$

where:

PE_y = the annual prediction error as measured by the difference between the actual earnings per share at the end of year y and the analyst's forecasts at the beginning of year y

D_y^q = the difference between the actual earnings per share observed in quarter q and the analyst's most recent forecast for quarter q

λ_q = an adjustment coefficient which indicates the extent to which the analyst revises the annual earnings forecast after observing the error in his earnings forecast for quarter q.

Finding each of the estimated regression coefficients (except the intercept) to be significantly different from zero, AE rejected H_0 in favor of H_1. The finding that the coefficients are significantly different from zero cannot, however, be used to reject H_0. To see why, consider a simple scenario. Suppose that analysts make annual and quarterly forecasts at the beginning of the year. Then upon receiving interim reports, they do not revise their forecasts of the remaining portion of the annual earnings

[1] Even if AE had properly specified their test, however, they would have obtained biased and inefficient parameter estimates since they tested a reduced form model rather than their original adaptive expectations models. This is illustrated in Section 4.

[2] Equation (1) is, in essence, the reduced form model of the original adaptive expectations equations developed by AE, their equation (2).

TAW_R_COCDR1#80Attachment
Page 538 of 739

number, but instead they revise their forecasts of the total annual earnings number when their interim forecasts are in error by substituting into their annual forecasts the known interim numbers in place of their earlier predicted values.[3] Undoubtedly, some firms will report higher earnings than analysts had forecast and some, lower. This, of course, will be true for both the annual and quarterly periods. Accordingly, we anticipate finding a significant cross-sectional association between annual forecast errors and quarterly forecast errors even when no revision of the remaining portion of the annual earnings number takes place. Indeed, in this simplified case, it can be shown (see Section 3 and the Appendix A) that $\lambda_1 = \lambda_2 = \lambda_3 = 1$.

Once we allow for analyst forecast revision of the remaining portion of the annual earnings when quarterly results appear, our conclusions are not fundamentally altered in any way. In particular, the λ's will be greater (less) than one if analysts revise their forecasts of the remaining portion of the annual earnings number in the same (opposite) direction as the most recent quarterly error. Hence, one cannot discriminate between H_0 and H_1 upon finding that the regression estimates of the λ's are other than zero, since the λ's will be identically equal to one if H_0 is true and significantly greater (smaller) than one if the *RP2* (*RP3*) version of H_1 is valid. The estimated λ's will equal zero only in the unusual case when no revision of the total annual earnings number conditional upon quarterly reports takes place. In order for this to happen, the revision of the remainder of the annual earnings number must be equal in magnitude and opposite in sign to the summed interim errors to date. In effect, analysts would maintain intact their earlier forecasts of the annual earnings number, regardless of the signals in the interim reports. By testing the λ's against zero instead of one, AE tested the wrong hypothesis. The finding that the λ's are insignificantly different from zero is evidence in favor of the *RP3* form of H_1, not evidence in favor of H_0, as AE maintained. Note, also, that since unbiased forecasts are sufficient to ensure a zero intercept, one cannot rely on the intercept term being insignificantly different from zero to distinguish between H_0 and H_1.

Finally, the anticipated dependency of annual forecast errors on quarterly forecast errors does not rely upon collinearity of quarterly forecast errors. Quarterly forecast errors could be completely independent of each other and still be significantly associated with annual forecast errors. Although it is possible for quarterly forecast errors (with or without revision) to be dependent, AE implicitly assumed independence and

[3] This is a necessary feature of *The Value Line Investment Survey*, the data base used by AE. Value Line analysts make both quarterly and annual forecasts. When interim reports of the year being predicted are available, the Value Line annual forecast equals the sum of the known interim numbers plus the forecasts of the remaining quarters of the year.

obtained very low partial correlation coefficient estimates.[4] We begin, then, by analyzing the independence case.

3. *Null Hypothesis of No Revision*

3.1 SIMULATION ANALYSIS

To support the claim that the AE findings are likely to arise when no forecast revisions of the remaining portion of the year are made, a simulation was performed. First, two sets of quarterly earnings-per-share numbers were randomly generated for each of forty-five hypothetical firms. One set was labeled actual and the other predicted.[5] Note that, by construction, all 360 numbers (forty-five firms, four quarters, two sets) have the same expected values. After the quarterly figures were summed to obtain annual amounts, a cross-sectional *OLS* regression was run with the annual difference between actual and forecasted earnings as the dependent variable, and the first three quarterly differences as the independent variables. The simulated numbers and the individual forecast errors are available upon request; the results of the *OLS* regression appear in table 1.

These results are similar to those reported by AE in that the estimated coefficients of all three forecast error variables are positive and significant (except for the intercept term), in spite of the fact that due to the nature of our simulation, we know in advance that no forecast revisions were made. The results are purely an artifact of the requirements that, under independence and no revision, the quarterly forecast errors must sum to the annual forecast error when the latter forecast is made prior to the receipt of any interim reports of the year being forecast. The result that the λ's are not identically equal to one is due to random error. Thus, any

[4] If analysts are rational, then they will take advantage of any ex-ante dependence in their forecast errors to improve their forecasts. Ex-ante dependence, therefore, assumes irrational forecasting (Box and Jenkins [1970, p. 129]), making the AE independence assumption quite palatable.

[5] Specifically, we employed three icosahedral dice to obtain values between 0.00 and 9.99 Each die has twice ten sides with pairs of sides marked from 0 through 9. The properties of such dice as random number generators are described by Gardner [1968].

TAW_R_COCDR1#80Attachment
Page 540 of 739

attempt to reject H_0 on the basis of the estimated parameter coefficients being nonzero is inappropriate.

It is evident what the results of the simulation should be. Analytically, the sampling rule can be expressed as:

$$PE_y = D_y^1 + D_y^2 + D_y^3 + D_y^4, \tag{2}$$

where D_y^q, $q = 1, 2, 3, 4$, are independently distributed random variables with zero expected values. This model differs from equation (1) in that D_y^4 has now been included and the model coefficients are no longer explicit. Since the quarterly forecast errors are independent by construction, it follows that the *OLS* regression estimates will be unbiased, or equivalently that the expected values of $\hat{\lambda}_q$, $q = 1, 2, 3$, will equal one and the expected value of the constant term will equal zero.[6]

3.2 FURTHER ANALYSIS

Additional insight into the defect in AE's test is gained by considering, in quarterly form, the adaptive expectations models (their equation (2)) which were used to derive our equation (1). Independence of the quarterly forecast errors is no longer assumed, and revision of quarterly forecasts is now allowable. We show that to discriminate between H_0 and H_1, the coefficients (λ's) must be tested against one when using equation (1).

AE's adaptive expectations equation (their equation (2)) may be written as:

$$\hat{A}_t \mid Q_{it} - \hat{A}_t \mid Q_{i-1,t} = \lambda_i(Q_{it} - \hat{Q}_{it} \mid Q_{i-1,t}) + e_{it}, \qquad i = 1, 2, 3 \tag{3}$$

where:

A_t = annual earnings per share of year t
$\hat{A}_t \mid \Phi_T$ = analysts' prediction of annual earnings per share of year t conditional upon information set Φ_T available at T
Q_{it} = reported earnings per share in quarter i of year t
$\hat{Q}_{it} \mid \Phi_T$ = analysts' prediction of earnings per share of quarter i of year t conditional upon information set Φ_T available at T
e_{it} = random disturbance in quarter i of year t.

In words, the annual earnings forecast revision in quarter i is a linear function of the (one-quarter-ahead) error made in forecasting quarter i's earnings. To clarify the potential hypothesis tests of λ_i, we express the

[6] See Johnston [1972, p. 169]. We also provide a simple, yet instructive, proof in Appendix A that should demonstrate the effect of the implicit additivity restriction on forecast errors under no revision.

TAW_R_COCDR1#80Attachment
Page 541 of 739

left-hand side of equation (3) in quarterly form:

$$(\hat{Q}_{1t} + \hat{Q}_{2t} + \hat{Q}_{3t} + \hat{Q}_{4t}) \mid Q_{1t} - (\hat{Q}_{1t} + \hat{Q}_{2t} + \hat{Q}_{3t} + \hat{Q}_{4t}) \mid Q_{0t} = \lambda_1(Q_{1t} - \hat{Q}_{1t} \mid Q_{0t}) + e_{1t}, \tag{4}$$

$$(\hat{Q}_{1t} + \hat{Q}_{2t} + \hat{Q}_{3t} + \hat{Q}_{4t}) \mid Q_{2t} - (\hat{Q}_{1t} + \hat{Q}_{2t} + \hat{Q}_{3t} + \hat{Q}_{4t}) \mid Q_{1t} = \lambda_2(Q_{2t} - \hat{Q}_{2t} \mid Q_{1t}) + e_{2t}, \tag{5}$$

$$(\hat{Q}_{1t} + \hat{Q}_{2t} + \hat{Q}_{3t} + \hat{Q}_{4t}) \mid Q_{3t} - (\hat{Q}_{1t} + \hat{Q}_{2t} + \hat{Q}_{3t} + \hat{Q}_{4t}) \mid Q_{2t} = \lambda_3(Q_{3t} - \hat{Q}_{3t} \mid Q_{2t}) + e_{3t}. \tag{6}$$

Revisions of the total annual earnings forecast are shown in equations (4) through (6). To test whether the annual forecasts are revised in response to quarterly errors, the appropriate tests are $\lambda_i = 0$, $i = 1, 2, 3$. Now, by making use of the fact that $\hat{Q}_{it} \mid Q_{it} = Q_{it}$ and rearranging, (4) through (6) can be written alternatively and equivalently as:

$$(\hat{Q}_{2t} + \hat{Q}_{3t} + \hat{Q}_{4t}) \mid Q_{1t} - (\hat{Q}_{2t} + \hat{Q}_{3t} + \hat{Q}_{4t}) \mid Q_{0t} = (\lambda_1 - 1)(Q_{1t} - \hat{Q}_{1t} \mid Q_{0t}) + e_{1t}, \tag{4'}$$

$$(\hat{Q}_{3t} + \hat{Q}_{4t}) \mid Q_{2t} - (\hat{Q}_{3t} + \hat{Q}_{4t}) \mid Q_{1t} = (\lambda_2 - 1)(Q_{2t} - \hat{Q}_{2t} \mid Q_{1t}) + e_{2t}, \tag{5'}$$

$$(\hat{Q}_{4t} \mid Q_{3t} - \hat{Q}_{4t} \mid Q_{2t}) = (\lambda_3 - 1)(Q_{3t} - \hat{Q}_{3t} \mid Q_{2t}) + e_{3t}. \tag{6'}$$

Revisions of the predicted (remaining) portion of the annual number are shown in (4′) through (6′). To test whether the predicted portions of annual earnings are revised in response to quarterly errors, the appropriate tests in (4′) through (6′) are $(\lambda_i = 1) = 0$, $i = 1, 2, 3$, or equivalently in (4) through (6), $\lambda_i = 1$, $i = 1, 2, 3$. Since AE combine (4) through (6) to obtain equation (1) above, then the coefficients in (1) should be tested against one, not zero, in order to achieve AE's repeated intent [1978, pp. 1–3, 7, 9] to determine "if analysts in fact use these quarterly deviations to revise the predicted portion of the annual number" [1978, p. 4].

3.3 COEFFICIENT VALUES AND REVISION BEHAVIOR

AE also attempt to use their regression results to make inferences about the nature of analysts' revisions. They distinguish three cases, labeled *RP1*, *RP2*, and *RP3*. In all three cases, analysts upon receipt of interim reports incorporate the realized quarterly number into their annual earnings forecast, and they observe the sign of the current quarter's forecast error, which is actual earnings minus expected earnings (see n. 3). Behavior differs in how analysts revise predictions of the remaining portion of annual earnings. Under *RP1*, no revision occurs. Under *RP2* (*RP3*), revision of the remainder of the year is in the same (opposite) direction as the sign of the forecast error.

TAW_R_COCDR1#80Attachment
Page 542 of 739

AE argue that under *RP1*, only λ_1 will be nonzero, and it will be positive. Since this is the no-revision case, the correct hypothesis would be that λ_1 equals one under *RP1*. Furthermore, *RP1* does not imply that future forecasting errors will not occur. Rather, when they do, no revision is made of remaining quarterly earnings of the year. Thus, λ_2 and λ_3 are also determinate under *RP1* with predicted values of one, so that under *RP1* and H_0, $\lambda_1 = \lambda_2 = \lambda_3 = 1$. Similarly, if the alternative hypothesis *RP2* (*RP3*) is valid, the appropriate null hypothesis is λ_i, $i = 1, 2, 3$, is greater (less) than one.

A test of equation (1) presents several econometric difficulties. As it stands, the equation represents a test of how the set of sequential quarterly forecast errors of analysts are related to their annual earnings forecast errors as of the start of the year. This regression, as can be seen in equations (4) through (6), contains spurious correlations.[7] A second drawback is that the fourth-quarter error is implicitly contained in the disturbance term.[8] This acts to bias estimates of the regression coefficients. Finally, although economic theory suggests that the quarterly forecast errors of analysts should be ex-ante independent, sampling variation will cause some ex-post dependence or collinearity. This sampling variation not only produces inefficient estimates but is a source of bias of unpredicted sign on the estimated coefficients.[9]

At this juncture, it is evident that equation (1) is seriously suspect as a vehicle for providing a meaningful test of analyst revision behavior. Whatever the merit of the theoretical analysis which precedes the reduced form model, it is likely that the model as a cross-sectional *OLS* regression will be defective for testing the revision behavior described by AE.

4. *Alternative Test of Forecast Revision*

AE's analysis provides another set of relations which are more useful for determining if analysts systematically revise their forecasts when interim earnings statements become available. Consider the regressions based on AE's equation (2), our equation (3):

$$FEPS_{q,y} - FEPS_{q-1,y} = \lambda_q(D_y{}^q) + u_{q,y} \qquad q = 1, 2, 3 \tag{7}$$

where:

$FEPS_{q,y}$ = the *forecasted* annual earnings per share made in quarter q for year y

[7] For example, in equation (4), $Q_{1t} - \hat{Q}_{1t} \mid Q_{0t}$ appears on both the left- and the right-hand sides.

[8] See Appendix A; what this would mean is that the term $E(x_4'x_4)$ would no longer equal zero. Other effects are that estimates will be imprecise, with large errors, and dependent on particular samples.

[9] The nature of the ex-post sample bias is shown analytically in Brown and Rozeff [1978*a*, pp. 3–4] and is demonstrated empirically in Section 4.

TABLE 2
Cross-Sectional Regressions on Actual Data

	λ's	t-Statistics*	R^2
Panel A: (Regressions with equation (7))			
Constant	0.002	0.001	0.41
λ_1	2.12	21.2, 11.2	
Constant	0.01	0.003	0.08
λ_2	1.42	15.9, 4.7	
Constant	−0.07	−3.50	0.29
λ_3	1.57	26.2, 9.5	
Panel B: (Regressions with equation (1))			
Constant	−0.14	−2.3	0.70
λ_1	3.17	10.3	
λ_2	1.31	1.7	
λ_3	1.68	3.4	

* With respect to the null hypothesis that the λ_q, $q = 1, 2, 3$, all equal zero and one in that order in panel A and equal one in panel B.

$u_{q,y}$ = a random error term with mean zero and constant variance.

Note that when no revision of the total annual earnings number conditional upon interim reports takes place (i.e., $FEPS_{q,y} = FEPS_{0,y}$ for all q), the estimated coefficients of quarterly forecast errors would be insignificantly different from zero. Conversely, if any of the estimates are significantly different from zero, then this is evidence that forecasts are revised on the basis of quarterly forecast errors, but perhaps only in the sense of *RP1*. To discriminate against *RP1* further, we next test to see if the coefficients (i.e., λ's) are significantly different from one. If they are, it is evidence that analysts revise future forecasts conditional upon realized quarterly numbers.

The regressions from (7) enjoy three distinct advantages over (1): (*i*) they do not contain spurious correlations; (*ii*) the use of just the most recent forecast error as the independent variable eliminates problems of multicollinearity and bias; and (*iii*) unlike equation (1), (7) allows us to discriminate between *RP1*, the hypothesis of no revision of future quarters, and "*RP0*," the hypothesis of no revision of the (total) annual number. The potential importance of ex-post bias and testing power is reflected in the empirical analysis that follows.

Using a sample of fifty Value Line firms and five years of quarterly forecasts for each, the regressions given by (7) were run and the results shown in panel A of table 2 were obtained.[10] Observe that the estimated coefficients in panel A are all significantly greater than one (t-values of

[10] See Brown and Rozeff [1978*b*] for further details on the sample selected. Sample size equals 243 due to missing observations. The sample period was 1972–76.

TAW_R_COCDR1#80Attachment
Page 544 of 739

11.2, 4.7, and 9.5), a finding that is consistent with the hypothesis that in all three quarters analysts do revise their forecasts of the predicted portion of annual earnings in a fashion consistent with the *RP2* version of the alternative hypothesis.

To complete the comparison with AE, we also tested their model (i.e., equation (1) above) on the same data and obtained the results shown in panel *B*. In testing the hypotheses that the λ's differ from one (rather than zero, as AE reported for their sample), we observe that only the first- and third-quarter forecast errors have significant coefficients (with lower *t*-values than in panel *A*); the second quarter does not.[11] What we conclude from this result, when compared to panel *A*, is that the finding of an insignificant coefficient for the second quarter is more likely to be caused by the econometric problems inherent in equation (1) and is not a reliable indication that the *RP2* version of H_1 is invalid.

Although these tests do appear to be more powerful than AE's in detecting revisions, we do not claim, as they do, that such revisions constitute improvements over the forecasts previously made. To examine forecast improvement we would need to specify an appropriate loss function over forecast errors plus an error metric and analyze forecast errors. This is outside the scope of this comment and hence is not pursued here. We should note, though, that neither we nor AE investigated forecast accuracy, a sine qua non for an investigation of forecast improvement.

5. *Concluding Remark*

We do not claim that analysts fail to revise their forecasts on the basis of interim earnings reports, nor do we maintain that Abdel-khalik and Espejo's findings are inconsistent with H_1. Rather, we take the position that (*i*) AE's findings, as they interpreted them, did not allow rejection of H_0, the hypothesis of no revision of remaining earnings, and (*ii*) even if the correct interpretation is given to the results of the AE test, there exists a more powerful test available than the one they elected to employ. In a larger sense, these kinds of problems are as subtle as they are serious. It is not sufficient to find empirical results consistent with a hypothesis motivated by one's prior theory. One must also consider whether these results could conceivably be obtained when alternatives to that hypothesis are true and whether the test to be employed is the most powerful one available.

[11] These findings are similar to AE's when the null hypothesis is restated in terms of the λ's being equal to one (i.e., the first- and third-quarter coefficients are significant, while the second-quarter coefficient is not).

TAW_R_COCDR1#80Attachment
Page 545 of 739

APPENDIX A

Proof of Expected Values of Regression Coefficients

We define our sampling rule under the null hypothesis, H_0, as follows:

$$Y = X_1 + X_2 + X_3 + X_4 \tag{A1}$$

where:

$$X_q = D_y{}^q,\ q = 1, 2, 3, 4$$

$$Y = PE_y, \quad \text{and}$$

the X_q, $q = 1, 2, 3, 4$, are independently distributed random variables with zero means.

Consider the following *OLS* regression to estimate the implicit coefficients of X_q, $q = 1, 2, 3$:

$$Y_i = \lambda_0 + \lambda_1 X_{1i} + \lambda_2 X_{2i} + \lambda_3 X_{3i} + U_i,\ i = 1, 2, \ldots, n. \tag{A2}$$

In matrix notation, and using deviation form, we can write (A2) as:

$$\underset{(n\times 1)}{y} = \underset{(n\times 3)}{x}\ \underset{(3\times 1)}{\lambda} + \underset{(n\times 1)}{u}\ . \tag{A3}$$

The *OLS* regression estimate using (A3) is:

$$\hat{\lambda} = (x'x)^{-1}x'\,y.$$

Substituting, from (A1) in matrix form, we obtain:

$$\hat{\lambda} = (x'\,x)^{-1}x'(xe + x_4)$$

where e is the unit vector. Since, by construction $E(x'\,x_4) = 0$, then:

$$E(\hat{\lambda}) = E[E(\hat{\lambda}\,|\,x)] = E[(x'\,x)^{-1}x'(xe)] = e.$$

Also, since (in the original notation):

$$\hat{\lambda}_0 = \bar{Y} - \hat{\lambda}_1\bar{X}_1 - \hat{\lambda}_2\bar{X}_2 - \hat{\lambda}_3\bar{X}_3$$

and given the zero means of our sampling rule, then:

$$\begin{aligned} E(\hat{\lambda}_0) = E[E(\hat{\lambda}_0\,|\,X)] \quad &= E[E(\bar{Y} - \hat{\lambda}_1\bar{X}_1 - \lambda_2\bar{X}_2 - \lambda_3\bar{X}_3\,|\,X)] \\ &= E[\bar{X}_1 + \bar{X}_2 + \bar{X}_3 + E(X_4\,|\,X) \\ &\quad \lambda_1\bar{X}_1 - \lambda_2\bar{X}_2 - \lambda_3\bar{X}_3] \\ &= E[E(X_4\,|\,X)] = E(0) = 0. \\ &\quad \text{Q.E.D.} \end{aligned}$$

CAPITAL BUDGETING IN THE DECENTRALIZED FIRM*

STEVEN F. MAIER† AND JAMES H. VANDER WEIDE†

In this paper we analyze the capital budgeting problem of an organization which contains a central headquarters and K divisions. The headquarters serves as the planner-coordinator of the capital budgeting process and is the only member of the organization which has access to the external capital markets. The K divisions make decisions regarding the set of capital projects each wants to accept. The capital budgeting problem of this decentralized organization is solved and analyzed with the aid of an algorithm based on mathematical decomposition. It is shown that (i) the decomposition algorithm does indeed converge to an optimal corporate solution, (ii) under reasonable assumptions, the marginal rate of return on the last dollar spent is the same for each division and is equal to the corporate headquarters' "cost of capital," (iii) in some circumstances, the decomposition model will only select integral projects, and (iv) the optimal choice of projects for the firm is made independently by the divisions, each acting in its own self-interest. This last feature of the capital budgeting model suggests that the firm may be able to achieve the informational economies usually associated with a decentralized organization structure.

Most contributions to the literature on the capital budgeting problem under certainty have focused on either (1) the problem of choosing whether to accept or reject a single project or (2) the problem of choosing from among a set of interrelated projects when total expenditures in each period are constrained by a capital budget. Although these contributions certainly enhance our understanding of many realistic capital budgeting situations, they do not provide a foundation for understanding the role that capital budgets themselves play in the planning process. The central theme of this paper is the development of a mathematical model that demonstrates the usefulness of capital budgets as both planning and control devices.

The capital budgeting problem in the multi-division firm is analyzed here with the aid of an algorithm based on mathematical decomposition [5], [6], and [8]. It is found that (i) the decomposition algorithm converges to an optimal corporate solution, (ii) under reasonable assumptions, the rate of return on the last dollar spent is the same for each division and is equal to the corporate headquarters' "marginal cost of capital," (iii) in some circumstances, the decomposition model will only select integral projects, and (iv) the optimal choice of projects for the firm is made independently by the divisions, each acting in its own self-interest. This last feature of the capital budgeting model suggests that the firm may be able to achieve the informational economies usually associated with a decentralized organization structure.

1. The Capital Budgeting Problem in the Single Division Firm

It is helpful to begin the analysis with a brief review of the capital budgeting problem facing the single-division firm. We assume in this model that (1) the firm's opportunity set includes single period borrowing and lending opportunities in addition to physical capital projects, (2) the firm chooses those physical and financial opportunities in its opportunity set which maximize the firm's horizon value, and (3) the firm's current choices are constrained in each time period by the cash flows associated with opportunities accepted before the start of this planning process. The

TAW_R_COCDR1#80Attachment
Page 549 of 739

reader will recognize that these are the assumptions which describe Weingartner's Basic Horizon Model [11].

Let

x_j = the fraction of project j accepted,

P = the set of available projects for the single division,

v_t = the dollar amount of lendings in period t,

w_t = the dollar amount of borrowings in period t,

a_{tj} = the net cash flow associated with one unit of project j in period t (a positive sign is used to represent a cash inflow; a negative sign, a cash outflow),

$\hat{a}_j$ = the horizon value of post-horizon cash flows associated with one unit of project j,

r_t = the lending rate in period t,

r'_t = the borrowing rate in period t,

D_t = the dollar amount of cash flows in period t associated with projects accepted prior to the start of the planning process,

T = the horizon period.

Then the capital budgeting problem for this single-division firm can be formulated mathematically as:[1]

$$\text{Maximize} \sum_{j \in P} \hat{a}_j x_j + v_T - w_T \quad \text{with respect to } x_j, v_t, w_t,$$

$$\text{subject to} \quad -\sum_{j \in P} a_{1j} x_j + v_1 - w_1 \leqslant D_1,$$

$$-\sum_{j \in P} a_{tj} x_j - (1 + r_{t-1}) v_{t-1} + v_t + (1 + r'_{t-1}) w_{t-1} - w_t \leqslant D_t \qquad (t = 2, \ldots, T)$$

$$0 \leqslant x_j \leqslant 1, \qquad j \in P,$$

$$v_t, w_t \geqslant 0, \qquad t = 1, 2, \ldots, T.$$

2. The Capital Budgeting Process in the Multi-Division Firm

The multi-division firm whose capital budgeting process we wish to analyze consists of a single corporate financial headquarters and K divisions. We assume that each of the K divisions has a set P_k of projects which it can consider for adoption, but that only the corporate headquarters has access to the external financial markets. In addition, we assume that the multi-division firm's objective is to maximize its horizon value, and that its decisions are constrained by the cash flows associated with its previously accepted projects. If we let μ_{tk} denote the cash flows generated by division k's accepted projects in period t, then the capital budgeting problem of our multi-division firm can be formulated mathematically as:

$$\text{Maximize} \sum_{j \in P} \hat{a}_j x_j + v_T - w_T \quad \text{with respect to } x_j, v_t, w_t, \tag{1}$$

$$\text{subject to} \quad -\sum_{k=1}^{K} \mu_{1k} + v_1 - w_1 \leqslant D_1, \tag{2}$$

$$-\sum_{k=1}^{K} \mu_{tk} - (1 + r_{t-1}) v_{t-1} + v_t + (1 + r'_{t-1}) w_{t-1} - w_t \leqslant D_t, \qquad t = 2, \ldots, T, \tag{3}$$

$$\mu_{tk} - \sum_{j \in P_k} a_{tj} x_j = 0, \qquad k = 1, \ldots, K;\ t = 1, \ldots, T, \tag{4}$$

$$0 \leqslant x_j \leqslant 1, \qquad j \in P; \quad v_t \geqslant 0,\ w_t \geqslant 0,\ \mu_{tk} \text{ unrestricted}$$

where $P = P_1 \cup P_2 \cup \cdots \cup P_K$.

The introduction into the model of the cash flow variables μ_{tk} gives the above

[1] One difficulty that can arise in the formulation of this model is in the computation of $\hat{a}_j$. Since the borrowing and lending rates can differ, the discount rate used to compute $\hat{a}_j$ is not always well defined. One possible solution to this problem would be to solve the problem parametrically for a series of post-horizon discount rates.

TAW_R_COCDR1#80Attachment
Page 550 of 739

formulation of the capital budgeting problem in the multi-division firm the special block-angular structure usually associated with models which are amenable to solution by mathematical decomposition. Because of this structure, the capital budgeting problem can be solved in the following steps:

1. The corporate headquarters sends to each division a set (one for each period) of initial capital budgets and horizon transformation factors.

2. Each division solves its own capital budgeting problem using the transformation factors, but not the capital budgets received from the corporate headquarters. In this step, each division accepts all projects with a positive horizon (or present) value and submits a proposal of total cash flow needs for each period that is the summation of the cash flows of all its accepted projects.

2. Each division then resolves its own capital budgeting problem by choosing those projects which maximize the horizon value of all project cash flows and also satisfy the initial budget constraints in every period. It then submits to the corporate headquarters the total cash flows for each period generated by its accepted projects.

3. The corporate headquarters uses the cash flow information it receives from the divisions and determines a new set of divisional budgets and transformation factors, as well as the amounts it should borrow or lend in each time period. The new budgets and transformation factors are then sent to the divisions.

4. This iterative process returns to step 2 until either (i) no division can submit a new proposal with a higher present value than any one it has submitted previously or (ii) the headquarters terminates the process at a suboptimal solution because the potential solution improvement is not worth the cost of the budgeting procedure.

5. When the iterative process is completed, the corporate headquarters sets the final capital budgets and transformation factors and sends them to the divisions. The divisions then independently select the set of projects which maximize their present value, evaluated by the final transformation factors, subject to the final capital budgeting constraints.[2]

In summary, the capital budgeting problem described above may be solved by decomposing it into $K + 1$ interrelated subproblems. The first K of these subproblems are called the division programs, and the remaining subproblem is called the executive program. We formulate each of these problems in the following sections of this paper and discuss the economic implications of the solution.

3. The Executive Program

The executive program is designed to provide the corporate headquarters with the budgets and transformation factors which it sends to the divisions at the beginning of each iteration in the solution procedure. In addition, it provides the optimal values of the corporate decision variables, v_t and w_t, for all values of t.

The executive primal can be formulated mathematically as:

$$\text{Maximize} \quad Z_E = \sum_{k=1}^{K} \sum_{q \in S_k} c_k^q \lambda_k^q + v_T - w_T \quad \text{with respect to } \lambda_k^q,\ v_t,\ w_t, \tag{6}$$

$$\text{subject to} \quad -\sum_{k=1}^{K} \sum_{q \in S_k} \mu_{1k}^q \lambda_k^q + v_1 - w_1 \leqslant D_1, \tag{7}$$

$$-\sum_{k=1}^{K} \sum_{q \in S_k} \mu_{tk}^q \lambda_k^q - (1 + r_{t-1}) v_{t-1} + v_t + (1 + r'_{t-1}) w_{t-1} - w_t \leqslant D_t, \qquad t = 2, \ldots, T, \tag{8}$$

$$\sum_{q \in S_k} \lambda_k^q = 1, \qquad k = 1, \ldots, K; \quad \lambda_k^q \geqslant 0,\ v_t \geqslant 0,\ w_t \geqslant 0, \tag{9}$$

[2] In order to avoid nonuniqueness of the division problem solutions at the final iteration, the values of the $\hat{a}_j$ should be altered by adding a small positive constant to each of them. This perturbation of the $\hat{a}_j$ will guarantee that the divisions utilize all of their final budgets, even if some of the funds are invested in marginal projects. (This observation is due to Børge Obel.)

TAW_R_COCDR1#80Attachment
Page 551 of 739

where μ_{tk}^q are the cash flows for division k's qth proposal, $c_k^q = \sum_{j \in P_k} \hat{a}_j x_j^q$ is the horizon value of all post-horizon cash flows included in division k's qth proposal, and S_k is the set of all proposals that have so far been submitted by division k.

The executive primal is similar to Weingartner's Basic Horizon Model. The major difference occurs in constraints (9). Instead of the division project constraints, we now have a constraint on the proposal weights. This difference is highly significant, since it indicates that the executive primal does not require detailed information on each individual project.

Given an optimal solution to the executive primal, the division budgets are given by

$$b_{tk} = -\sum_{q \in S_k} \mu_{tk}^q \lambda_k^q, \qquad t = 1, \ldots, T, \tag{10}$$

where λ_k^q are the optimal proposal weights found in (6)–(9).

The executive dual can be formulated as:

$$\text{Minimize} \quad \sum_t \rho_t D_t + \sum_k \sigma_k \quad \text{with respect to } \rho_t, \sigma_k, \tag{11}$$

$$\text{subject to} \quad -\sum_t \rho_t \mu_{tk}^q + \sigma_k \geqslant c_k^q \qquad q \in S_k, k = 1, \ldots, K, \tag{12}$$

$$\rho_T \geqslant 1, \tag{13}$$

$$-\rho_T \geqslant -1, \tag{14}$$

$$\rho_{t-1} - (1 + r_{t-1})\rho_t \geqslant 0, \qquad t = 2, \ldots, T, \tag{15}$$

$$-\rho_{t-1} + (1 + r'_{t-1})\rho_t \geqslant 0, \qquad t = 2, \ldots, T; \quad \rho_t \geqslant 0; \ \sigma_k \text{ unrestricted.} \tag{16}$$

The variables ρ_t in the executive dual are associated with the corporate constraints (7)–(8) in the executive primal. Since the objective function in the executive primal is formulated in terms of horizon values, ρ_t measures the horizon value of an additional dollar in period t, assuming such an addition would not change the basis. Combining (13) and (14) we see that

$$\rho_T = 1. \tag{17}$$

Likewise, combining (15) and (16), we have

$$(1 + r_{t-1}) \leqslant \rho_{t-1}/\rho_t \leqslant (1 + r'_{t-1}), \qquad t = 2, \ldots, T. \tag{18}$$

Thus, the internal intertemporal transformation rate between period $t-1$ and t must lie between the borrowing and lending transformation rates. We see below that the ρ_t are sent at the beginning of each solution iteration to the divisions and used in the division programs to value funds in each period in terms of the horizon.

To interpret the remaining dual variables, σ_k, we must take a closer look at (12). Since ρ_k is unrestricted in sign and its sum is minimized in the dual objective, we have

$$\sigma_k = \max_{q \in S_k} \left\{ c_k^q + \sum_t \rho_t \mu_{tk}^q \right\}, \qquad k = 1, \ldots, K. \tag{19}$$

The term in brackets is the horizon value of all projects in the qth proposal, where ρ_t is used to transform the prehorizon cash flows to horizon values. Therefore, σ_k is the horizon value of the best proposal received so far from division k.

4. The Division Programs

After the divisions have received the budgets and transformation factors from the corporate headquarters, they must choose that set of projects in their opportunity set

TAW_R_COCDR1#80Attachment
Page 552 of 739

which maximizes the division objective subject to the budget constraints. The division program can be formulated mathematically as:

$$\text{Maximize} \quad Z_k = \sum_{j \in P_k} \hat{a}_j x_j + \sum_t \rho_t \mu_{tk} - \sigma_k \quad \text{with respect to } x_j \in P_k,\ \mu_{tk}, \tag{20}$$

$$\text{subject to} \quad -\mu_{tk} + \sum_{j \in P_k} a_{tj} x_j = 0, \quad t = 1, \ldots, T, \tag{21}$$

$$-\mu_{tk} \leqslant b_{tk}, \qquad t = 1, \ldots, T, \tag{22}$$

$$0 \leqslant x_j \leqslant 1, \qquad j \in P_k; \quad \mu_{tk} \text{ unrestricted in sign.} \tag{23}$$

The division program will be solved twice in our solution procedure. The first time the problem is solved, the division completely disregards the budgetary constraints (22) and selects those projects with a positive net horizon value. The test of whether an acceptable proposal can be generated is to compare the computed horizon value of all accepted projects with the value of the best previous proposal the division has submitted (measured, recall, by σ_k). This process may be carried out mechanically by solving the division program with constraints (22) deleted. If the objective function value at the solution is positive, then a proposal will be submitted to the headquarters, consisting of the values μ_{tk}, $t = 1, \ldots, T$, and the value c_k computed as:

$$c_k = \sum_{j \in P_k} \hat{a}_j x_j. \tag{24}$$

The second time the division problem is solved, the budget constraints (22) will be included in the formulation and a second proposal will be generated. (It turns out that if the proposal with all budgets deleted fails to pass the test for submission, then all proposals with budget constraints will also fail the test, and therefore, this part of the procedure can be skipped.) This second proposal consists again of the net cash flows, μ_{tk}, and the value of post horizon flows computed by (24).

In some instances, the division or the corporate headquarters may feel that these two proposals do not completely satisfy the needs of the firm. For example, the headquarters may feel that some of its budgets are extremely rigid, while others are considerably more flexible. The solution to this nonequivalence of various portions of the budget is to permit the divisions to relax selectively some of the budget constraints and submit additional proposals. It has been shown that the use of multiple proposals can significantly speed the convergence of decomposition type algorithms (see Glassey[6]).

5. Stopping Rules

The decomposition algorithm has two possible termination mechanisms. The first criterion is signaled when no division can submit a new proposal and indicates that the global optimal solution has been reached (see Dantzig [4, p. 452] for a proof of this result). Unfortunately, much of the computational experience with decomposition indicates that this termination may require a great many iterations. If either the cost or the time required to perform an iteration is large, then termination at less than the absolute best solution may be required.

The second termination mechanism is based on the calculation of an upper bound on the optimal objective function value. The bound, which follows from Lasdon [8, p. 163], on the executive program's objective value is:

$$Z_E^B \equiv \operatorname*{MIN}_l \left\{ Z_E^l + \sum_{k=1}^{K} Z_k^l \right\} \tag{24A}$$

where l is an index for the iteration number, Z_E^l is the value of the executive program's objective function on the lth iteration, and Z_k^l is the value of the uncon-

TAW_R_COCDR1#80Attachment
Page 553 of 739

strained division program k's objective function on the lth iteration. The minimum is taken over all bounds that have been generated, one on each iteration. (One must be careful that the division programs are solved using the transformation factors ρ_t corresponding to Z_E^l when the Z_k^l values are generated.) The stopping rule is then defined by:

$$\text{IF } Z_E^B - Z_E^C \leqslant \epsilon, \text{ then terminate the algorithm,}$$

where Z_E^C is the current value of the executive program's objective function. Epsilon (ϵ) represents the maximum potential improvement if the iterative process were to continue.

6. Properties of an Optimal Solution

Having described the decomposition procedure in some detail, we now examine two interesting properties of an optimal solution to the capital budgeting problem. The first pertains to the relationship between the transformation rates ρ_t used by the divisions to evaluate cash flows in terms of horizon values and the dual variables Π_{tk} associated with the divisions' budgets. The transformation rates, recall, measure the change in the horizon value of the firm which would occur if an additional dollar were available in period t. Division k's dual variables, on the other hand, measure the change in the horizon value of division k's cash flows which would occur if it had an additional dollar in its period t budget. It is intuitive that if the current solution to the capital budgeting problem is optimal, then the value of the period t transformation rate should equal the value of the period t dual variable for each division. That this is in fact correct is shown in Theorem 1 below.

The second property of an optimal solution concerns the possibility of accepting fractional projects. Many practitioners view this possibility as a major criticism of programming approaches to the capital budgeting problem (see, for example, Hughes and Lewellen [7]). Theorem 4 states a sufficient condition for all projects to be integral.

The presentation of the proofs to Theorems 1 through 4 can be simplified if we rewrite the division program (20)–(23) in a different form. This new form is obtained from the original by introducing slack variables g_{tk} in constraints (22) and then eliminating μ_{tk} from constraints (20) and (21). The reformulated division program is then given by:

$$\text{Maximize } Z_k = \left[\sum_{j \in P_k} \hat{a}_j x_j + \sum_t \rho_t g_{tk}\right] - \left[\sigma_k + \sum_t \rho_t b_{tk}\right] \text{with respect to } x_j \in P_k \text{ and } g_{tk} \tag{26}$$

$$\text{subject to } -\sum_{j \in P_k} a_{tj} x_j + g_{tk} = b_{tk}, \qquad t = 1, \ldots, T, \tag{27}$$

$$0 \leqslant x_j \leqslant 1, \qquad j \in P_k, \tag{28}$$

$$g_{tk} \geqslant 0, \qquad t = 1, \ldots, T.$$

The reader may find this formulation of division k's capital budgeting problem familiar. In fact, if one disregards the constant term in the objective function (given by the second set of square brackets), associates the transformation factors ρ_t with utility and assumes zero post-horizon cash flows, then the model is identical to the

TAW_R_COCDR1#80Attachment
Page 554 of 739

Baumol-Quandt reformulation of the original Lorie-Savage-Weingartner capital budgeting model (see [2]).

It is also useful to have available the dual to division k's capital budgeting problem. The dual of (26)–(28) is given by:

$$\text{Minimize} \quad \left[\sum_t b_{tk}\Pi_{tk} + \sum_{j\in P_k}\delta_j\right] - \left[\sigma_k + \sum_t \rho_t b_{tk}\right] \quad \text{with respect to } \Pi_{tk} \text{ and } \delta_j, \tag{29}$$

$$\text{subject to} \quad -\sum_t a_{tj}\Pi_{tk} + \delta_j \geqslant \hat{a}_j, \qquad j \in P_k, \tag{30}$$

$$\Pi_{tk} \geqslant \rho_t, \qquad t = 1, \ldots, T, \tag{31}$$

$$\Pi_{tk} \text{ unrestricted}, \quad \delta_j \geqslant 0.$$

To establish the first property of an optimal solution, we must guarantee that the optimal ρ_t transformation factors can be given their usual interpretation as evaluators of a marginal increase in the cash flows D_t; namely, that for each time period t, there exists a small positive constant (ϵ_t), such that increasing (decreasing) D_t by ϵ_t will increase (decrease) the value of the executive program's objective function (7) by $\epsilon_t\rho_t$. In order to guarantee this interpretation for ρ_t, we require the following nondegeneracy assumption:

NONDEGENERACY ASSUMPTION. *The final solution of the executive program* (7)–(10) *is nondegenerate.*

Before we proceed with the proof of the first property of an optimal solution to the capital budgeting problem of the multi-division firm, we will find it convenient to establish the following lemma.

LEMMA 1. *If the nondegeneracy assumption is satisfied, then for any* $j \in P_k$ *in the final solution for division program k the following is true*:

$0 < x_j < 1$ *implies* $\hat{a}_j + \sum_t a_{tj}\rho_t = 0$,
$x_j = 0$ *implies* $\hat{a}_j + \sum_t a_{tj}\rho_t \leqslant 0$,
$x_j = 1$ *implies* $\hat{a}_j + \sum_t a_{tj}\rho_t \geqslant 0$.

This lemma states that any fractionally accepted projects must have a zero net horizon (or equivalently present) value, any accepted projects must have nonnegative net horizon value, and any rejected projects must have nonpositive net horizon value. Although this may appear to be an intuitive result, it requires careful proof, since the x_j's are found from the solution of the division program (26)–(28), with the budget constraints active, while the ρ_t's are found from the solution of the executive program (6)–(9), which never considers the projects individually. We will construct a proof by contradiction.

PROOF. Suppose there exists a j that satisfies $0 < x_{\bar{j}} < 1$ in the optimal division program solution and $\hat{a}_{\bar{j}} + \sum_t a_{t\bar{j}}\rho_t > 0$. We shall show that a small change ΔD_t in each of the D_t variables results in an increase of greater than $\sum_t \rho_t \Delta D_t$ in the executive program's objective function value, thus contradicting the optimality of the solution.

Select an $\epsilon > 0$, such that

(i) $x_{\bar{j}} + \epsilon < 1$ and

(ii) a simultaneous change of $-\epsilon \cdot a_{t\bar{j}}$ for each D_t does not cause a basis change in (6)–(9).

Such an ϵ must exist by virtue of our nondegeneracy assumption.

A simultaneous change of $\Delta D_t = -\epsilon \cdot a_{t\bar{j}}$ in each D_t should cause an increase in the value of the objective function (6) of:

$$\sum_t \rho_t \Delta D_t. \tag{32}$$

Now suppose that the change in D_t's is assigned entirely to the division budget, b_{tk}, corresponding to the division k that contains project $\bar{j}$. How will the value of the

TAW_R_COCDR1#80Attachment
Page 555 of 739

objective function for this division be affected? We see immediately that if project $\bar{j}$ is increased by ϵ, then (27) shows that the budget change can be completely absorbed by this project, and that the total change in the objective function (26) for this division becomes $\epsilon\hat{a}_{\bar{j}} - \sum_t \rho_t \Delta D_t = \epsilon(\hat{a}_{\bar{j}} + \sum_t \rho_t a_{t\bar{j}})$. But this must be strictly greater than zero by our initial assumption for project $\bar{j}$. Thus, the division program objective function now indicates that a new proposal can be submitted to the executive program. By (12), this new proposal will increase the value of σ_k, and therefore (11) shows that the value of the executive program will increase by $\sum_t \rho_t \Delta D_t$ plus this increase in σ_k. This increase is more than we expected in (32), so we conclude that the original assumption of a positive present value for project $\bar{j}$ leads to a contradiction.

A similar proof can be constructed for the case where $\hat{a}_{\bar{j}} + \sum_t a_{t\bar{j}} \rho_t < 0$ by considering a small change of $\epsilon \cdot a_{t\bar{j}}$ in the D_t's.

The proof for the second and third cases is similar to the proof given above for the first case. However, it must be kept in mind that only an increase in x_j is feasible for the second case and a decrease in x_j for the third case.

We now state and prove Theorem 1.

THEOREM 1. *If the nondegeneracy assumption is satisfied, then the dual variables, ρ_t, corresponding to the optimal corporate problem will satisfy the condition: $\rho_t = \Pi_{t1} = \Pi_{t2} = \cdots = \Pi_{tK}$ for $t = 1, \ldots, T$, where Π_{tk} stands for an optimal dual solution to the division k program.*

PROOF. It is sufficient to show that corresponding to the optimal division program solution, (x_j, g_{tk}), can be constructed a dual solution, (Π_{tk}, δ_j) such that substituting ρ_t for Π_{tk} will satisfy dual feasibility and complementary slackness.

The complementary slackness condition for the division program (26)–(28) is:

$$\delta_j(x_j - 1) = 0 \quad \text{for } j \in P_k, \tag{33}$$

$$\left(\hat{a}_j + \sum_t a_{tj}\Pi_{tk} - \delta_j\right)x_j = 0 \quad \text{for } j \in P_k, \tag{34}$$

$$(\Pi_{tk} - \rho_t)g_{tk} = 0 \quad \text{for } t = 1, \ldots, T. \tag{35}$$

Substituting ρ_t for Π_{tk} in (31) and (35) results in these conditions holding trivially. It remains to be shown that (30), (33) and (34) hold. We consider three cases. For $0 < x_j < 1$, $\delta_j = 0$ satisfies (33). Conditions (30) and (34) then follow from the results of Lemma 1. For $x_j = 1$, (33) is satisfied for any $\delta_j \geqslant 0$. Select a value for δ_j so that (34) is satisfied. Such a value must exist by Lemma 1. This selection of δ_j will also satisfy (30). For $x_j = 0$, (34) is always satisfied, (33) is satisfied with $\delta_j = 0$, and (30) is satisfied by the results of Lemma 1.

We have thus shown that by the proper selection of values for δ_j, ρ_t can be made to satisfy both dual feasibility and complementary slackness. The proof is complete.

Before concluding this discussion of transformation factors, it is important to consider the impact of possible degeneracy on the division program. Degeneracy in (26)–(28) is an extremely likely event, since many of the g_{tk} variables could be basic at zero level. For example, if a division were required to accept only one project partially, all other projects being fully accepted or rejected, then all but one of the g_{tk} variables would be basic. Since a positive g_{tk} represents an unutilized resource, we would expect all g_{tk} variables to be zero in the optimal solution. Therefore, we have basic g_{tk} variables at zero level in the optimal solution, i.e., degeneracy.

If degeneracy does occur in a division program, then the possibility exists for many optimal dual solutions (Π_{tk}, δ_j). We have shown in Theorem 1 that one of these

TAW_R_COCDR1#80Attachment
Page 556 of 739

satisfies $\rho_t = \Pi_{tk}$. We will now show that at least for increases in the budgets b_{tk}, ρ_t is the appropriate shadow price.

THEOREM 2. *If the nondegeneracy assumption is satisfied and if the optimal solution to division program k experiences an increase Δb_{tk} in its period t budget, then the value of division k's objective function will increase by $\Delta b_{tk} \cdot \rho_t$.*

PROOF. The proof is in two steps. First, we will show that $\rho_t \Delta b_{tk}$ is an upper bound on the increase in the objective function value. Second, we will show that this bound can always be attained.

Since any feasible solution to the dual program (29)–(31) gives a bound on the division program's objective (26), and since a change in b_{tk} does not affect dual feasibility, we have

$$Z_k' \leqslant Z_k + \Delta b_{tk} \cdot \Pi_{tk}, \tag{36}$$

or substituting the specific dual solution $\rho_t = \Pi_{tk}$ we obtain $\Delta Z_k \leqslant \Delta b_{tk} \cdot \rho_t$.

Next, we observe that any increase in b_{tk} can always be absorbed by a corresponding increase in g_{tk}. Such an increase in g_{tk} will by (26) increase Z_k by $\Delta g_{tk} \cdot \rho_t$. Substituting Δb_{tk} for Δg_{tk} completes the proof.

The result in Theorem 2 begs the question: What happens if a budget b_{tk} is decreased? The answer is embodied in Theorem 3.

THEOREM 3. *If the optimal solution to division program k experiences a decrease, Δb_{tk}, in its period t budget, then the decrease in the value of the objective function must be at least* Maximum $_{\Pi_{tk}} \Pi_{tk} \cdot |\Delta b_{tk}|$ *where the maximum is taken over all optimal solutions to the dual problem* (29)–(30). *Furthermore, for a small enough change Δb_{tk}, the bound can always be attained.*

PROOF. Since both Δb_{tk} and ΔZ_k are nonpositive, (36) can be written as $|\Delta Z_K| \geqslant \Pi_{tk} \cdot |\Delta b_{tk}|$. However, this result must hold for all optimal solutions to the dual, thus proving the first part of the theorem. The second part of the theorem follows from the fact that at least one of the optimal dual solutions must be valid for measuring the change in the division program objective function value for small enough changes in the right-hand side.

As a partial answer to the potential criticism that programming models lead to nonintegral solutions, we can show the following result for our decomposition approach:

THEOREM 4. *If the optimal solution to the original capital budgeting problem* (1)–(4) *is unique, and if we borrow or lend in every time period, then the optimal solution to the decomposition model will only select integral projects* (*i.e., either $x_j = 0$ or $x_j = 1$, for all $j \in P$*).

PROOF. The proof follows along the same lines as that constructed by Weingartner [11, p. 153] for the original basic horizon model.

The major assumption of this theorem, that the firm be in a net lending or borrowing position in each time period, would appear to be realistic in many practical situations. However, even if a few time periods should violate this condition, the number of nonintegral projects should be very small.

7. Discussion

The use of prices to direct the search for an optimal solution in a primal decomposition procedure has been recognized since the first published papers on the method. The distinguishing feature of the decomposition algorithm proposed here is that it is both price and budget directed. We will now discuss why the incorporation

TAW_R_COCDR1#80Attachment
Page 557 of 739

of budgets in the decomposition procedure is justified both as a device for control and as a mechanism for planning.

The incorporation of budgets in the division programs has the effect of reducing the size of the feasible set of available capital projects. In fact, it can be shown that when the final budgets are computed, the optimal solution for the company as a whole will always occur at an extreme point of this restricted set of feasible projects. Therefore, when the prices are correctly determined, as they will be in this algorithm, the division itself can actually select the projects to be undertaken, namely, it simply solves (20)–(23) one last time using the final budgets and discount factors. This contrasts sharply with other primal decomposition models that are only price directed. In these methods, the final project selection has to be made by the corporate headquarters. Therefore, the budgets are needed as a control device if we are to provide this final step in the decentralized decision-making process.

If prices alone are passed to the divisions, only one plan for capital expenditure will be submitted by the division to the corporate headquarters at each iteration of the algorithm. Although this is sufficient to guarantee convergence of the procedure to the optimal solution, it is usually a very slow and expensive process. By incorporating budgets into the iterative stage of the algorithm, each division can now submit multiple plans for capital expenditure on any given iteration. It has been shown (see [6], for example) that the more proposals that are generated, the smaller will be the required number of iterations to achieve a near optimal solution. Thus, budgets are very useful as planning mechanisms, since they can eliminate potentially expensive (both in time and effort) iterations.

Finally, it is the possibility of simultaneously adjusting budgets and discount factors in the division program that leads to the result given in Theorem 1. We have thus shown that in a programming model of the Weingartner type, it is possible to achieve consistency between the marginal internal rates of return, Π_{tk}, and a market determined cost of capital ρ_t. In fact, the algorithm provides a mechanism for adjusting the budgets and market rates so as to maximize the horizon value of the firm while simultaneously achieving this consistency.

8. Conclusion

The capital budgeting problem under certainty for the multi-division firm is modeled in this paper and solved with the aid of an algorithm based on the theory of mathematical decomposition. This model has several desirable features absent in previous programming approaches to the problem. In addition, the organizational and computational efficiencies achieved with the aid of the decomposition algorithm seem to make this approach implementable for many decentralized firms. Finally, it is easy to show that extensions of the model to more realistic settings such as a rising supply curve for funds, multiple lending and borrowing opportunities, and chance-constraints on the firm's liquidity position can all be incorporated into the executive program's formulation without affecting either the basic algorithmic procedure or the equilibrium results.[3]

[3] The authors gratefully acknowledge the assistance of Professors Kalman J. Cohen, David W. Peterson, and Julie H. Zalkind on earlier drafts of this paper. They also wish to acknowledge two anonymous referees, whose comments enabled them to clarify the proofs of several of the theorems.

A DECISION ANALYSIS APPROACH TO THE COMPUTER LEASE-PURCHASE DECISION

STEVEN F. MAIER* and JAMES H. VANDER WEIDE†

Scope and purpose—The manager of computer services must periodically decide whether to lease or purchase a new computer. Computer leases usually involve a higher expected cost than a purchase decision, but they also reduce risk by providing insurance against the financial losses which often occur when a new computer technology is announced. In this paper the authors present a decision theoretic model of the computer lease-purchase decision which can be used by the manager of computer services to improve his decision making ability in this important area.

Abstract—The lease-purchase decision is analyzed with the use of decision analysis. The formulation proposed captures both the stochastic and sequential nature of this decision, and should provide a substantial improvement over a simple present value approach.

INTRODUCTION

In his seminal article on lease analysis, Vancil[9], distinguishes between two, entirely different types of lease. The financial lease, according to Vancil, is a long-term non-cancellable lease whose term is usually approximately equal to the expected economic life of the leased property. Since the lessor does not expect to re-lease the property after the lease term has expired, the total contractual lease payments must be sufficient to cover both the original cost of the property and the interest on the lessor's investment. The cash flows associated with the financial lease are thus known with a high degree of certainty. Furthermore, only one decision regarding a particular financial lease is likely to be made within the decision maker's horizon. Vancil, as well as those analysts who followed (e.g.,[1], [3], [5], and [8]), found a fairly straightforward present value analysis appropriate for the financial lease decision.

The operating lease, on the other hand, is a short-term, cancellable lease whose expected term is much less than the expected economic life of the leased property. Since the contractual lease payments are not sufficient to cover the original cost of the property plus interest, the lessor must attempt to re-lease the property after the term of the lease has expired. Once the term has expired, the lessee must also make another decision. The decision is whether to renew the lease or to obtain the services of the property in a different way. From an analytical viewpoint, there are two distinguishing features of the operating lease: (1) the total lease payments are not known with certainty and (2) both the lessor and the lessee must make a sequence of lease decisions within their investment horizons. In this paper we present a model of the lease-purchase decision, from the lessee's point of view, which is most appropriate in situations where these two features are dominant. Although the model presented in this paper was applied specifically to the computer lease-purchase decision, it should be apparent that the model is applicable to other operating lease-purchase decision problems as well.

EXAMPLE

The salient features of the computer lease-purchase decision can be exposed clearly with the aid of a simple example designed to illustrate the nature of the economic tradeoff between

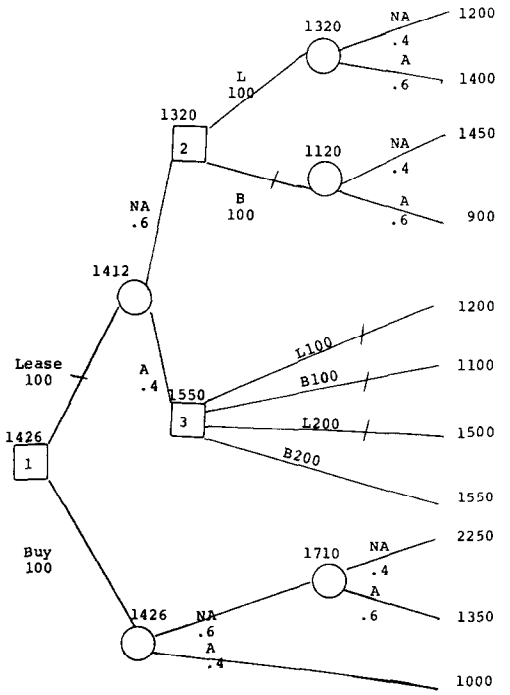
TAW_R_COCDR1#80Attachment
Page 560 of 739

(i) the lower periodic payments, and hence increased profits, associated with the purchase decision and (ii) the insurance against future losses from technological obsolescence provided by the lease decision. For the purposes of this example we assume

(1) The firm's current decision is whether to lease or purchase a Model 100 computer.

(2) If the firm purchases the Model 100, it does not have to make another decision at the beginning of period 2 because a purchase decision is considered permanent during the planning horizon.

(3) If the firm leases the Model 100, the set of decisions available in the second period depends on whether an announcement occurred during the first. If an announcement did occur during the first period, then the firm can lease the 100, purchase the 100, lease the new Model 200, or purchase the 200. If an announcement did not occur, then the firm must decide again whether to lease or purchase the Model 100.



(4) The total profits over the horizon period associated with each initial decision depend on whether or not and when a Model 200 is announced.

(5) The probability that an announcement will occur during the first period is 0.4. If an announcement does not occur during the first period, then the probability of an announcement in the second period increases to 0.6. If an announcement does occur during the first period, however, then the probability of another announcement in the second period is zero.

(6) The firm's objective is to maximize the expected value of its profits.

A decision tree diagram of the just described decision problem is displayed in Exhibit 1. The total profits associated with each decision-chance event sequence are displayed at the right of the tree. The numbers next to each circular node in the tree represent the expected monetary values of the chance events. The numbers next to the square nodes, on the other hand, are the expected monetary values of the "best" decision emanating from that node. Since the buy decision has a higher expected monetary value, the assumed decision maker should buy the Model 100 at the first decision period.

The above analysis indicates that the buy decision is recommended for a decision maker who wants to maximize the expected monetary value of the outcomes. Daniel Bernoulli[2] recognized already in the 18th century, however, that the expected monetary value criterion

Note:

A = announcement
NA = no announcement
L = lease
B = buy

Exhibit 1. Decision tree—expected monetary value.

TAW_R_COCDR1#80Attachment
Page 561 of 739

may not be appropriate in decision situations characterized by risk. Instead, Bernoulli suggested that the decision maker should maximize the expected utility of the dollar outcomes. Almost two centuries later (see von Neumann and Morgenstern[10]), the maximum expected utility criterion was shown under weak assumptions to lead to a correct ordering of the decision maker's preferences. A decision tree diagram of the above computer lease-purchase decision problem for a decision maker with a logarithmic utility function is shown in Exhibit 2. We see that this decision maker would choose to lease, rather than buy, the Model 100 at the first decision period.

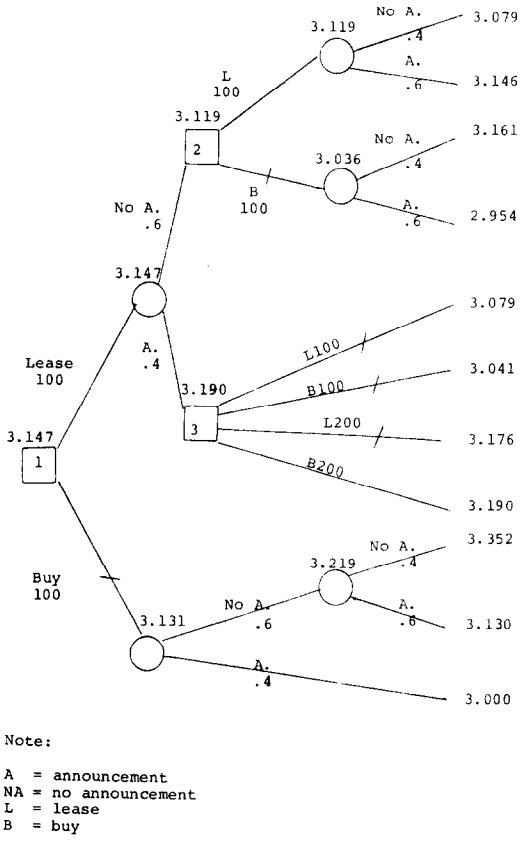


Exhibit 2. Decision tree—expected utility.

GENERAL FORMULATION

Though the computer lease-purchase problem is not usually as simple in practice as the above example would indicate, the basic economic tradeoffs remain the same. We thus can describe the problem in terms of (i) the set of decisions available to the decision maker at each decision point during the planning horizon, (ii) the conditional probability distributions associated with the chance event or events, (iii) the cash flows associated with each decision-chance event sequence and (iv) the decision maker's utility function. We shall consider these one at a time.

The decision set. The decision maker in the above example was assumed to have only two choices available at the initial period—to lease or purchase the Model 100 computer. In practice, it is usually feasible to use not only the most recent computer model but models from previous generations as well. In general terms we assume that the decision maker must choose a decision, d_t, at the beginning of period t, from among an available set of decisions, D_t. Furthermore, D_t depends on both his current status, or mode of operation, and whether or not a new computer generation has been announced. If we let the state variable, S_t,* denote the decision maker's current status and the state variable, X_t, denote the number of periods since the last major announcement, then we can write the decision set as all $d_t \in D_t(S_t, X_t)$.

*The state variable, S_t, should tell us not only whether the decision maker currently owns or leases a particular computer model, but when a purchase was made as well. There are various ways to accomplish this, some more efficient than others. If handled properly, however, this variable should present no unusual computational requirements.

TAW_R_COCDR1#80Attachment
Page 562 of 739

The conditional probability distributions. The uncertainty introduced by the possibility of technological change is captured in our model by the state variable, X_t, which measures the number of periods since the last major new model announcement, as of the beginning of period t. The probability that $X_{t+1} = x$ depends on the value of the state variable in the previous period, X_t, and is given by $P_t(X_{t+1} = x|X_t)$. A value of $X_{t+1} = 0$ indicates that an announcement occurred in the interval between t and $t+1$, and a value of $X_{t+1} = X_t + 1$ indicates no new announcement occurred.

In many practical situations, it is reasonable to assume that in addition to previous announcements, only one major announcement will occur during the planning period. This assumption can be modeled by permitting both positive and negative values of X_t, where $|X_t|$ is equal to the number of periods since the major announcement and the sign of X_t indicates whether the new major announcement has occurred. This construction implies that $P_t(X_{t+1} = x - 1|X_t = x) = 1$ for all $x = 0, -1, -2, \ldots$. In other words, the variable X_t is no longer a random variable once the announcement has occurred.*

The cash flows. If the decision maker purchases the property, his cash flows usually consist of an initial outlay, a stream of net profits resulting from use of the property, tax savings from depreciation and interest allowances, and cash received or spent when the property is resold or salvaged. The stream of net profits and the resale value of the property are quite sensitive to the announcement of a major improvement in computer technology. The tax savings from depreciation allowances depend mainly on existing tax laws and when the property was purchased. If the decision maker leases the property, his cash flows consist only of the lease payments, the net profits from use of the property and the tax savings from the allowance for lease payments.

The above considerations suggest that the cash returns, r_t, received by the decision maker in period t depend on S_t, the current status of the decision maker at the beginning of period t, X_{t+1}, the result of the random event determining the time of the major announcement, and d_t, the decision actually made at the beginning of period t. We denote this functional dependence by $r_t(S_t, X_{t+1}, d_t)$.

The utility function. With regard to the decision maker's objective, we assume that he behaves in accordance with the von Neumann–Morgenstern axioms. That is to say, we assume that he chooses that decision which maximizes his expected utility for money. Since we are considering a multiperiod framework, it is appropriate to discount the utility received in later periods by the decision maker's time preference factor, α, raised to the correct power.

Solution methodology. Having formulated the basic elements of the lease–purchase decision problem, it is time to discuss how optimal solutions to this problem can be obtained. Obviously, the suggestion to graph the problem decision tree and fold it back, as we did in the above simple example, would in most realistic cases be impractical. Instead, we present a dynamic programming recursion which, though based on much the same principle as folding back a decision tree, is capable of solving fairly large scale versions of the lease–purchase problem.

Let

$f_t(S_t, X_t)$ = the maximum discounted expected utility from cash flows occurring in period t and all subsequent periods,

$U[r_t(S_t, X_{t+1}, d_t)]$ = the utility from cash flows occurring in period t,

$U[r_{T+1}(S_{T+1}, X_{T+1})]$ = the utility from cash flows occurring in all periods after the horizon.

Then a dynamic programming recursion which solves the problem described above is given by

$$f_t(S_t, X_t) = \text{Max} \sum_x P_t(X_{t+1} = x|X_t)\{U[r_t(S_t, x, d_t)] + \alpha f_{t+1}(d_t, x)\} \tag{1}$$

$$\text{w.r.t.} \quad d_t \in D_t(S_t, X_t)$$

$$f_{T+1}(S_{T+1}, X_{T+1}) = U[r_{T+1}(S_{T+1}, X_{T+1})]. \tag{2}$$

*The use of both positive and negative values for the state variable X_t is primarily a computational simplification. An alternative mechanism that accomplishes the same goal is to have a third state variable which can take on only two values, the first indicating no new announcement has occurred, while the second indicates that the announcement has occurred.

TAW_R_COCDR1#80Attachment
Page 563 of 739

This recursion must be used to find the optimal d_t for $t = 1, \ldots, T$, starting with T. The optimal first period decision is given by finding the value $f_1(S_1, X_1)$. Since the number of states for each state variable, in this case 2, is relatively small, the amount of computer time required to obtain a solution even for large T is not significant.

DISCUSSION

In this paper we formulate and solve one version of the lease–purchase decision problem under uncertainty. The formulation which we propose captures both the stochastic and sequential nature of this problem. The algorithm which solves this formulation is easily programmable and is capable of solving realistically sized examples. On the negative side, however, the model does require at least three types of informational inputs which may be difficult to supply in some practical situations. These are (i) estimates of the conditional probability that a new computer generation will be announced in any period given the time of the previous announcement, (ii) estimates of the cash flows resulting from each decision-chance event sequence and (iii) estimates of the utility that the decision maker associates with each cash flow. It seems that several comments about these information requirements are in order.

First, although the decision maker is unlikely to have precise knowledge of either the probability of an announcement in any period or the effect of that announcement on each period's cash flows, he is likely to have formulated some beliefs about these variables from past history, articles in current periodicals, conversations with other computer specialists, etc. The authors firmly believe that the decision maker should take full advantage of this information even though some of it is subjective. For the alternatives are either to make a completely arbitrary decision or to avoid the decision problem altogether.

Second, although the model explicitly treats the uncertainty of a new announcement, nothing has been said about the uncertainty that is implicit in making a cash flow projection. Fortunately, the utility function approach is sufficiently robust to incorporate this uncertainty as well. All the user must do is to determine a distribution of possible cash flow outcomes that can be associated with a given state (S_t, X_{t+1}) and possible decision d_t. Thus we have $\tilde{r}_t(S_t, X_{t+1}, d_t)$ treated as a random variable. However, the utility of this cash flow random variable can be found by the usual methods of decision theory, see for example Raiffe[7], leaving the dynamic programming recursion given by equations (1) and (2) essentially unchanged.

Third, assigning utilities to dollar outcomes is not as difficult as one may at first think. In fact there are at least two legitimate approaches to this task. The first approach requires answers from the decision maker regarding his preferences between a series of uncertain events. If the decision maker is consistent in his performance, his utility function can be deduced easily from his answers. A complete description of this approach is contained in Raiffa[7]. The second approach is to deduce the decision maker's utility function from a small set of general properties which he would agree his utility function should have. If, for instance, the decision maker asserts that he is risk averse and that his relative aversion to risk remains constant as his wealth increases, then his utility function can only take one of the following forms (see Pratt[6]):

$$u(W) = \frac{1}{\gamma} W^{\gamma}, \qquad 0 < \gamma < 1$$

$$u(W) = \frac{1}{\gamma} W^{\gamma}, \qquad \gamma < 0$$

$$u(W) = \log W.$$

The authors successfully used the second approach in the application which generated this study.

It is important to realize that the use of a utility function greatly simplifies the analysis, while still capturing the uncertainties that make this problem unique. An alternative to the use of a utility function would be the method of stochastic decision trees described by Hespos and Strassmann[4]. Unfortunately, our experience indicates that this methodology is unworkable for a realistic application, since it is computationally sensitive to the number of decision points that are embedded in the model.

TAW_R_COCDR1#80Attachment
Page 564 of 739

Finally, it should be recognized that every decision model is in some sense a simplification of reality. When choosing between models, however, the decision maker should ascertain whether or not the model at least captures the essential features of the problem structure. In the authors' opinion, present value or internal rate of return models omit too many of the essential features of the computer lease–purchase decision problem to be useful. The above described model is offered as a simple and practical alternative which does capture the essential economic tradeoffs characterizing this problem.

A Practical Approach to Short-Run Financial Planning

Steven F. Maier and James H. Vander Weide

Steven F. Maier and James H. Vander Weide are both Associate Professors of Business Administration at the Graduate School of Business Administration at Duke University.

Introduction

Efficient management of the short-run investment/financing portfolio can often generate a significant improvement in a firm's return on investment.[1] Commercial banks, public accounting firms, and cash management consulting firms now offer a variety of computer aids designed to improve short-run financial decision-making, such as information on bank cash balance reports, current interest and foreign exchange rates, lock-box collections, and bank disbursements. The model described here improves the entire planning process by integrating cash forecasting and optimization models with the newly available reporting systems.

The financial manager's short-run portfolio problem was first modeled as a linear program by Robichek, Teichroew, and Jones [6] in 1965. The linear programming model was later expanded by Mao [2], Orgler [4], and Pogue and Bussard [5] to include the possibility of unequal time periods, additional deterministic constraints, and chance constraints. Recently, Srinivasan [7] and Zionts [8] have investigated the use of more efficient solution techniques based on the special structure of one version of the model.

Although linear programming models expand the ability of the cash manager to evaluate alternative short-run financial strategies, they are often extremely cumbersome to use. According to Orgler [3], a linear programming model of the firm's short-run portfolio problem will typically include 300 to 500 constraints and 2,000 to 4,000 variables. Such large models are not only expensive in computer time, but they also require a large amount of data input. Furthermore, the cash manager may often find it difficult to use and interpret models of this complexity. This would appear to make current linear programming models inappropriate for the rapid analysis required of financial decision-makers.

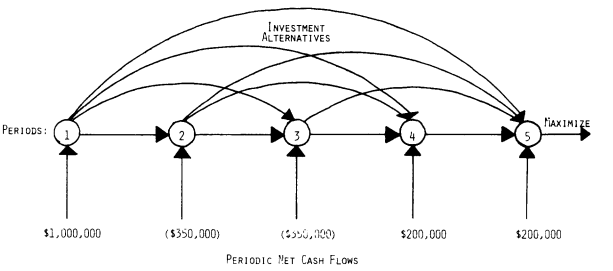
This paper describes a linear programming model of the short-run financial/investment decision that we

[1] A good discussion of the potential benefits from aggressive portfolio management is contained in "Cash Management" [1].

© 1978 Financial Management Association

TAW_R_COCDR1#80Attachment
Page 567 of 739

feel overcomes these difficulties. Our short-run financial planning model is designed for non-technical users; it is readily available on a world-wide time sharing computer network.[2] The model is designed to provide: rapid input of all necessary user-supplied data, maximum interaction between the user and the model, and output reports that the financial manager can easily interpret. With the aid of this model, the financial officer can plan and execute short-run financial decisions in a matter of minutes.



The Nature of the Planning Problem

The nature of the short-run financial planning problem can be illuminated by the schematic diagram shown in Exhibit 1. The circles in the diagram represent the time periods in the firm's planning horizon. Time periods may be measured in days, weeks, months, or any combination of them. It would not be unreasonable, for instance, to have a planning horizon consisting of five daily time periods, three weekly periods, and then five monthly periods.

The arrows at the bottom of the diagram represent the firm's projected cash flows. In this example, the firm expects a net cash inflow of $1,000,000 in Period 1, net outflows of $350,000 in Periods 2 and 3, and net inflows of $200,000 in Periods 4 and 5. Because sources and uses of funds must be equal in every period, the net cash flows indicated by these arrows constrain the firm's short-run financial activities. The firm can invest no more than $1,000,000 in Period 1, must plan to have $350,000 available in cash in Periods 2 and 3, and so on. (Although the diagram has been drawn to depict investment of funds, the model allows both investment and financing opportunities.)

While the arrows at the bottom of the diagram represent externally-generated cash flows, the arrows in the body of the diagram represent all the possible ways the financial manager can choose to invest funds over time. The horizontal arrows, for instance, represent the conservative policy of always investing in a single-period instrument, such as a repurchase agreement. Although this policy assures that the firm will meet its second and third period financial requirements, it very likely will not maximize the rate of return on investment. The uppermost arrow, connecting Periods 1 and 5, represents investment in an instrument with a four-period maturity. If the firm invests $1,000,000 in this instrument at Period 1, it will

Exhibit 1. The Short-Run Financial Planning Problem

be forced to borrow to meet the financial requirements of the intervening Periods 2 and 3.

Which investment policy should the firm follow? The answer depends on the magnitude of both current and projected interest rates. Given these rates, the firm could evaluate the total investment return associated with each feasible plan, choosing the one with the highest return. This will be a difficult task in most realistic situations, simply because there are very many possible plans. A primary virtue of a computerized short-run financial planning model is that it can search the set of possible alternatives very quickly to determine the optimal plan.

Modeling the Short-Run Financial Planning Problem

Our primary goal is to develop a user-oriented tool for the cash manager. Any model that satisfies this goal should be easily accessible (*i.e.*, no waiting for the computer staff to get to our job), allow rapid input of all necessary data, provide easily interpretable reports, and capture the essence of the short-run financial planning problem described above.

Mathematical Formulation

To meet the stipulation that the input data requirements be modest, it is desirable to use a relatively simple model formulation. One possibility is a network model of the type proposed by Srinivasan [7] and Zionts [8]. Network models, however, are inflexible with respect to the kinds of financial constraints they allow. We therefore elected to use a standard linear programming model along with a sophisticated matrix generator to conserve valuable computer storage. One virtue of a matrix generator is its ability to translate the data input from a very user-oriented form to the equations required by the linear program. A similar report generator handles the translation from the

[2]The program is available as part of Chemical Bank's CHEMLINK cash management Product System.

TAW_R_COCDR1#80Attachment
Page 568 of 739

linear programming output to the user reports.

The formulation we chose seeks to maximize the horizon value of the short-term portfolio, subject to a sources equal uses requirement and a limited number of user-specified linear constraints on the dollar amounts invested in various combinations of financial instruments.

In symbols, the formulation is:

Maximize $Z =$

$$\sum_{j=1}^{J} \sum_{i=1}^{T-1} a_{iT}^{j} \cdot X_{iT}^{j} - \sum_{k=1}^{K} \sum_{i=1}^{T-1} b_{iT}^{k} \cdot Y_{iT}^{k}$$

subject to

$$\sum_{j=1}^{J} \sum_{i=1}^{t-1} a_{it}^{j} \cdot X_{it}^{j} - \sum_{j=1}^{J} \sum_{i=t+1}^{T} X_{ti}^{j} + \sum_{k=1}^{K} \sum_{i=t+1}^{T} Y_{ti}^{k} - \sum_{k=1}^{K} \sum_{i=1}^{t-1} b_{it}^{k} \cdot Y_{it}^{k} = e_t \quad t = 1,2, \ldots, T$$

$$\sum_{i=1}^{T} \sum_{t=1}^{T} \left(\sum_{j=1}^{J} c_{it}^{jl} X_{it}^{j} + \sum_{k=1}^{K} d_{it}^{kl} Y_{it}^{k} \right) = f_l \text{ for } l = 1, \ldots, L.$$

where

- X_{it}^{j} = total dollars invested in security j at decision point i and maturing in period t;
- Y_{it}^{k} = total dollars borrowed from source k at decision point i that must be repaid in period t;
- a_{it}^{j} = principal plus interest received in period t on a dollar invested in security j in period i;
- b_{it}^{k} = principal plus interest due in period t on a dollar borrowed from source k in period i;
- e_i = cash requirement in period i. A negative number implies a cash inflow. (Note: this would be net of any compensating balance requirements needed to support lines of credit.);
- c_{it}^{jl}, d_{it}^{kl}, f_l = user-specified constants.

Discrete Time Periods

The model user must specify both the length and number of the time periods in his planning horizon. Once these are set, the model assumes that all decisions occur at the beginning of a period. Unfortunately, financial instruments come in a wide variety of maturities, and it is not always possible to choose periods in such a way that all instrument maturity dates coincide with decision points.

To allow for this possibility, we have incorporated two additional assumptions in the model. On the investment side, we assume that any dollars received between decision points from maturing securities are reinvested at the daily repurchase agreement rate, until the next decision is made. On the borrowing side, we require that funds be available on, or before, the due date. Thus, the dollars necessary for repayment of loans are added to the requirement of the preceding decision point and then are invested at a daily rate until they are actually needed. Although the above assumptions are somewhat arbitrary, they are necessary in order to provide flexibility in the length of the time periods and the types of investment instruments.

Finite Horizon

In a world of upward sloping yield curves, there are only two reasons why the linear programming model will ever select short-term investments. First, the cash manager may predict that interest rates will soon rise, allowing a higher total return to be earned with an initial short-maturity investment and reinvestment at the higher rates. Second, the cash manager may have a net requirement for funds in the near future. Since neither of these factors is relevant for post-horizon time periods, the model will often leave the financial officer with an illiquid portfolio by selecting long maturity investment instruments for decision periods at or near the horizon. If the horizon is relatively distant and the manager intends to implement only the first period recommendation before again solving the model, the "finite horizon" problem can be safely ignored. Where this is not the case, the user can handle the horizon problem by assessing an interest penalty that is proportional to the length of time that a security is held beyond the horizon point. Thus, the interest penalty is most severe for long-term investments, which the model would otherwise have selected.

User Orientation

The short-run financial planning model was especially designed to be user-oriented. The five principal data requirements are 1) number and duration of investment periods, 2) cash flow projection, 3) borrowing limitations, 4) instrument descriptions, and 5) interest rate projection. Since data from previous runs can be stored, the model is especially easy to use once the first case is run, because only data *changes* need be entered on subsequent runs. The optimal short-run plan is reported through a series of financial

TAW_R_COCDR1#80Attachment
Page 569 of 739

statements showing the amounts of each instrument bought, sold, and currently held during each period. Because data are easy to enter and solutions are reported rapidly, the user is encouraged to test the implications of various future economic decisions through a series of "what if" questions.

Model Specifications

The short-term financial planning model has the following characteristics: 1) The model accepts up to 25 planning periods. The user can specify the length of each period; 2) The model permits the user to specify a borrowing limitation, which can vary from period to period, on his or her line of credit; 3) The model will accommodate up to 15 investment or financing instruments, each of which can have a unique maturity and yield; 4) The yields on investment instruments can be modified over time via separately specified interest rate projections; and 5) A special feature controls investments that may extend beyond the planning horizon. The user may either entirely disallow such investments, or permit them but extract an interest penalty.

The output from the model gives three sets of information for each time period: maturing securities, new security purchases, and current security holdings. Each of these information sets is given as of the beginning of each investment period. The user has the option to delete any portion of the output not required.

The output also contains a marginal short-term investment rate analysis. This incremental analysis indicates the value of any additional funds the firm can make available for investment in period t, or, when the firm is projecting a net cash outflow in a period, the value of reducing this cash outflow. Such information can help the firm decide whether it should expedite some cash inflows or postpone the payment of specific payable items.

Potential Users

The short-run financial planning model is a potentially useful tool for either the net borrower or the net investor of short-term funds. For a firm that is a net borrower, the model is most useful for analyzing the economic tradeoffs in borrowing long vs. short, as well as the sensitivity of this maturity decision to interest rate fluctuations. For a firm that is a net investor, the model will quantify the added return from investments with greater risk, such as Eurodollar C.D.s, and examine the benefits of longer term investments, such as 180-day C.D.s, compared to a simple policy of rolling over short-term repurchase agreements.

Two conditions determine whether the model will add sufficient additional precision to financial decision-making to justify its cost. The first is rather obvious: the firm must have a large enough short-term investment/borrowing portfolio so that a savings of 5 to 10% will be significant. The second is more subtle: since the model depends on a firm's ability to project its cash flows, a firm that cannot forecast cash flows with reasonable accuracy will not find the model useful. In practice, this consideration depends on both the industry in which the firm operates and the quality of the accounting and information systems available to the treasurer.

The authors have worked with several medium-sized utilities that satisfy both conditions. Over the course of a year, the firms are net short-term borrowers of about $60 to $90 million. They rely strongly on the commercial paper market to satisfy their borrowing needs, but they are never sure what maturity paper it is best to float. In this case, the model is used to evaluate the risk-return tradeoff associated with various maturity strategies.

Example

The example shown in Exhibit 2 demonstrates some of the capabilities of the short-term financial planning model. The example contains two 7-day time periods, followed by two 14-day time periods, and finally three 28-day time periods. At the beginning of each period, the firm is allowed to borrow up to $2,000,000 from its line of credit or to sell 30-day maturity commercial paper. With its excess cash, the firm can invest in a 30-, 60-, or 90-day C.D. or in an over-night repurchase agreement. During the first two periods the firm expects cash inflows totaling $3,400,00, with a net cash outflow of $5,200,000 in the third period. Interest rates over the planning period are anticipated to fall slightly.

We will focus our attention on the decisions made during the first three periods. In the first two periods, the basic problem is to choose the appropriate investment instruments to maximize profits by minimizing borrowing costs. The case is not clear. On the one hand, interest rates are expected to fall, and longer-term C.D. investments yield more than the repurchase agreement. By buying a C.D., the firm could "lock in" the high current C.D. rate. On the other hand, a large cash outflow is expected in the third period, and the repurchase agreement might allow the firm to minimize the cost of financing this outflow. The com-

puter model has selected the repurchase agreement (see lines 1 and 2 of Output Description).

In the third period, the firm must finance part of its large anticipated cash outflow. Here the tradeoff is between the use of lower cost but less flexible commercial paper and the very flexible but higher cost line of credit. The computer model, taking into account the cash inflows that will occur in periods 4 and 5, chooses to use the higher cost line of credit (see line 3 of Output Description). The logic is simply that it will prove less expensive to borrow for only 14 days on the line of credit than to pay the lower cost commercial paper rate for 30 days.

In examining the data presented in Exhibit 2, the reader should keep in mind that, in practice, a user will probably want to examine the sensitivity of the solution to the interest rate projection and cash flow estimate. It is possible to formulate and test a variety of economic possibilities.

Conclusion

The model described in this article provides a tool for corporate financial officers to examine a wide range of possible short-term investment/financing strategies. The power of the model lies in its ability to make such comparisons almost instantaneously, at nominal cost to the user. In a world in which financial decisions must be made quickly, we believe that the computerized short-run financial planning model will prove to be an important new development in the field of cash management.

What Lockbox and Disbursement Models Really Do

STEVEN F. MAIER and JAMES H. VANDER WEIDE*

I. Introduction

MANAGEMENT of the firm's cash collection and disbursement systems is an important responsibility of the firm's treasurer. In fulfilling this responsibility, the treasurer's primary goal is to increase the amount of funds available for investment. On the cash collection side, this is frequently accomplished through the location of regional collection points known as lockboxes. Lockboxes increase the amount of funds available for investment by reducing the delay between the time the customer mails the check and the time funds are credited to the firm's account. On the disbursement side, the goal of increasing the amount of funds available for investment is achieved by disbursing funds from either "remote" or "control" locations. This serves to extend the delay between the time the firm mails the check and the time it is presented to the firm's bank for payment.

The fixed and variable costs of using bank provided lockbox and disbursement services are such that it is rarely profitable for a firm to have a lockbox or disbursement site in every city. Instead, the firm will work with a bank that does cash management studies to determine a smaller set of lockbox and disbursement locations that maximize the difference between total system benefits and costs.

A lockbox study consists of two parts. First, the study bank samples the firm's current remittances to determine the location of the firm's customers and the mail and availability times associated with the firm's current collection system. Second, the study bank designs an optimal lockbox system. If the float and cost savings of the new system are substantial, the firm will change its current system as recommended by the bank.

The problem of choosing the best set of lockbox sites is called the Lockbox Location Problem. This problem has been extensively studied by management scientists working in both academic and banking environments. Their work has produced a set of solution procedures used by most banks doing lockbox studies. Over the past seven years, the authors have been involved in the implementation of such solution procedures in over three dozen banks nationwide.

Disbursement studies are performed very much like lockbox studies. From a sample of the firm's checks, the bank estimates the average clearing times for the firm's current disbursing system. Using a database of nationwide clearing times and special optimization algorithms, the bank then determines the best set of disbursing banks as well as the assignment of vendors to these banks.

The problem of finding the best set of disbursing banks is called the

Page 575 of 739

Disbursement Bank Location Problem. Like the Lockbox Location Problem, this problem has been extensively studied in the literature. One of the formulations developed in this literature has been successfully implemented by the authors at a dozen banks.

This paper reviews the state of the art of lockbox and disbursement studies that banks perform for their corporate clients. In contrast to most academic papers on these subjects, we spend little time discussing optimization algorithms. Instead, we concentrate our attention on the issues involved in the practical implementation of lockbox and disbursement systems. In our opinion, banks who focus on these implementation issues offer far better cash management services to corporate clients than do those banks who worry about minor differences in algorithms.

II. The Lockbox Location Problem

The Lockbox Location Problem can be described mathematically as follows:

$$\text{Minimize } \sum_{i=1}^{m}\sum_{j=1}^{n} A_{ij}X_{ij} + \sum_{j=1}^{n} F_jZ_j + \sum_{i=1}^{m}\sum_{j=1}^{n} C_{ij}X_{ij} \tag{1}$$

$$\text{subject to } \sum_{j=1}^{n} X_{ij} = 1 \quad \text{for} \quad i = 1, \cdots, m \tag{2}$$

$$X_{ij} \leqslant Z_j \quad \text{for} \quad i = 1, \cdots, m; \qquad j = 1, \cdots, n \tag{3}$$

$$\sum_{j=1}^{n} Z_j \leqslant k \tag{4}$$

$$X_{ij} \geqslant 0 \quad \text{for } i = 1, \cdots, m; \qquad j = 1, \cdots, n \tag{5}$$

$$Z_j = 0 \text{ or } 1 \quad \text{for } j = 1, \cdots, n \tag{6}$$

where

A_{ij} = $\alpha T_{ij} D_i$ the opportunity cost of \$-float arising when customer group i's checks are sent to lockbox j,
α = the firm's annual opportunity cost of capital,
k = the maximum number of lockboxes that can be selected,
T_{ij} = average mail time in days from group i to lockbox j + average availability time in days from lockbox j to group i's bank,
D_i = average daily incoming funds from group i,
C_{ij} = variable cost of sending group i's checks to bank j,
X_{ij} = one if group i's checks are sent to lockbox j, zero otherwise,
F_j = the fixed charge per period for maintaining lockbox j,
Z_j = one if lockbox j is used, zero otherwise.

In this formulation, the objective is to minimize the opportunity cost of dollar float plus the fixed and variable costs of the lockbox system. Constraint set (2) insures that all checks are assigned to a lockbox, while constraint set (3), along with (6), insures that no check is sent to a "closed" lockbox. Constraint (4) is often used when the fixed charges F_j are not easily obtainable.

Research on the Lockbox Location Problem falls into two categories: (1)

TAW_R_COCDR1#80Attachment
Page 576 of 739

formulation and economic analysis and (2) mathematical optimization techniques. The papers by Kramer [15], Stancill [27], McAdams [19], Kraus, Jansen and McAdams [17], Shanker and Zoltners [26] and Maier and Vander Weide [20] fall in the first category. The papers by Baker, Maier and Vander Weide [1], Bulfin and Unger [3], Ciochetto, Swanson, Lee and Woolsey [5], Corneujols, Fisher and Nemhauser [7], Fielitz and White [11], Levy [18], Mavrides [22], Nauss and Markland [23] and Stone [31] fall in the second.

III. Data Requirements and Issues

To solve the Lockbox Location Problem, the analyst needs to divide the firm's customers into "homogeneous" groups, obtain data on the fixed and variable costs of maintaining a lockbox system, the mail times from group i to lockbox j, the availability times from lockbox j to group i's drawee bank, the mail and availability times for the firm's current system and the average daily incoming funds from group i, and find an efficient algorithm for evaluating the set of possible lockbox sites. At each stage the analyst must make important decisions that can have a significant effect on the value the firm receives from the lockbox system. As we consider each of these stages, we shall discuss the issues facing the analyst at that stage.

3.1 *Homogeneous Customer Groups*

Since the mathematical formulation does not address the issue of how to form homogeneous customer groups, the analyst must employ his judgment to design groups that are relatively homogeneous relative to mail and availability times, and, at the same time, are not so refined or complex to substantially increase the cost of analysis.

At one extreme the analyst can simply group customers by states or, possibly, 2-digit zip code areas. Simple groupings such as these significantly reduce the cost of collecting mail times and availability times, and by keeping the number of customer groups to a minimum, are both easy to analyze and implement.

The primary disadvantage of grouping customers by states or 2-digit zip codes is that it ignores the sometimes substantial differences between customers within the group. Such differences are especially pronounced when some of the firm's customers use controlled disbursing. Controlled disbursing gives the customer the ability to maximize disbursement float and to obtain timely information on check presentments. To work effectively, however, controlled disbursing often requires the customer to write checks on banks located in other regions of the country. Whereas a lockbox located in Los Angeles would no doubt best serve the customer who both mails and draws his checks from this city, a Chicago lockbox could very well be superior for a customer who draws checks on a North Carolina bank. Differences caused by the use of controlled disbursing cannot be ignored since one survey done by the authors has shown that more than 70% of the Fortune 500 firms use this practice.

At the other extreme, the analyst can treat each individual customer as a separate customer group. Although this has some merit in theory, it is prohibi-

tively expensive because it requires extensive data collection and complex implementation instructions for the firm's accounts receivable department.

A middle ground is to treat some of the firm's largest customers as single-member customer groups and to group all the remaining customers by 2- or 3-digit zip code areas. This alternative recognizes some of the more significant differences between customers in a state or zip code area, and yet is relatively easy to implement.

The analyst's choice of homogeneous customer groups can also have a significant effect in the design of lockbox systems for firms with many divisions. For such firms, it is both economically and administratively expensive to have each division instruct its customers to send remittances to, say, 10 lockbox sites. Accordingly, multi-division firms often instruct all customers of smaller divisions to remit to only one of the sites selected. By assigning all customers of this division to a separate customer group, it is possible to consider this practice within the framework of the overall optimization process.

3.2 *Fixed and Variable Costs*

The mathematical formulation requires the analyst to obtain information on the fixed and variable costs associated with each lockbox site. Since there are about 50 relevant lockbox cities with perhaps two or three banks in each city offering lockbox services, the analyst must obtain cost information from more than 100 banks. In gathering these costs, the analyst must recognize that bank charges for "good" customers may be significantly less than charges quoted to the general public; in addition, the charges may change frequently in response to market pressures.

Given the high cost of obtaining data on fixed and variable lockbox charges, the analyst must decide whether to obtain this information or not. Most analysts have decided not, partly based on their experience that float benefits between cities are frequently greater than cost differences between banks. These analysts approach the Lockbox Location Problem as follows:

1. Determine the dollar value of float benefits required to justify an additional lockbox site, for example a float reduction of $50,000 might be needed to expand the system by one additional bank.
2. Starting with one lockbox open, then two, etc. determine the optimal location of lockbox cities using city average float values. Stop this sequential analysis when the addition of one more city fails to meet the test in step 1.
3. Select candidate banks in each city determined by step 2 based on credit relationships, service quality, interface capabilities, size of the lockbox operation, and other sometimes intangible factors.
4. Reoptimize to determine specific banks and the assignment of customers to banks.

Special consideration is also given to existing lockbox bank relationships. At an early stage in the lockbox study, the firm's customers are reassigned within the existing system of lockbox banks. This so called "current system optimal" is much less costly to implement than the addition of new lockbox banks. Accordingly, improvements determined by the above four-step process are measured

TAW_R_COCDR1#80Attachment
Page 578 of 739

against this current system optimal base instead of the float levels found in the system as currently operated.

3.3 *Mail and Availability Times*

Mail and availability times play a key role in the analysis of lockbox systems. With regard to these times the analyst faces several important issues.

1. In comparing the firm's current collection system to the "optimal" lockbox system, the analyst needs to decide whether to use Phoenix-Hecht Surveyed Mail Times or a sample of actual mail times to measure the mail float in the current system. (There is universal agreement that the mail times surveyed by Phoenix-Hecht, Inc., a Chicago-based consulting firm, are the best and most comprehensive times to use in finding the optimal system.) If the analyst chooses to use actual mail times, he must recognize that there are a great many measurement errors caused by the unscientific nature of the sampling process, e.g. the date may have been incorrectly stamped on the envelope, the date may have been stamped on the envelope at a late stage in the mail process, etc. If he chooses to use Phoenix-Hecht mail times, the analyst must recognize that these were collected under certain ideal circumstances that may not characterize the firm's actual experience. Phoenix-Hecht mail times, for instance, are measured from a central location within each customer region, whereas his customers may not remit from that central location.
2. With regard to availability times, the analyst must first decide whether to use availability times at all. Early implementations of the lockbox model ignored availability times on the grounds that availability differences from city to city were small, since the Federal Reserve guarantees a maximum of two day availability no matter where a check is deposited. If the analyst decides he wants to include availability times in the analysis, he must choose whether to measure them by quoted Federal Reserve availabilities, city average bank availabilities or individual bank availabilities. Since 1979 most analysts have relied on individual bank availabilities, a transition which caused significant changes in the solutions found (see the paper by Ferguson and Maier [8]). Individual bank availabilities tend to reduce the optimal number of lockboxes and to change their locations.
3. If the analyst decides to use both mail and availability times, he must also decide how to combine these times into a total collection time. A problem arises because of differences in the units by which mail and availability times are measured. For an insightful discussion of this issue the reader is referred to the paper by Nauss & Markland [24].

3.4 *Amount of Incoming Funds from Region i*

To estimate the amount of incoming funds from customer region i the analyst typically collects a sample of the firm's incoming checks covering a one month period. For the purposes of analysis, the analyst wants to make sure that the sample is representative of the firm's long run collection experience. Since most

firms experience considerable seasonality and frequent changes in customer collection patterns, this is no simple matter.

One approach to this problem, developed by the First National Bank of Chicago and called Dynamic Lockbox Analysis, forecasts shifts in corporate remittance patterns as well as trends in mail and availability times during the initial design stage of the lockbox system.

3.5 *Summary*

The decisions the analyst makes regarding the design of the data collection process can have a significant impact on the quality of the solutions obtained. Early lockbox analyses relied on crude customer groupings, small unrepresentative samples of the firm's checks and unquestioning use of mail times to represent differences in city mail plus availability times. Recent improvements in data collection and a better understanding of the consequences of alternative data choices have greatly improved the quality of lockbox system design. We estimate these improvements to be approximately 10–15% of the total float savings in value.

IV. Optimization and Heuristic Algorithms

Once the analyst has formed appropriate customer groups and gathered the requisite data, he must employ an algorithm to evaluate the float savings associated with each combination of lockbox sites.

In their award winning paper [7], Cornuejols, Fisher and Nemhauser analyze various exact and approximate algorithms to the Lockbox Location Problem. Their results may be summarized as follows:

1. It is difficult to find an algorithm that always produces an optimal solution to the Lockbox Location Problem in a reasonable amount of computer time. In fact, since the Lockbox Location Problem is NP-complete, there is no known algorithm to the problem with an upper bound on running time that is polynomial in the problem parameters.
2. A theoretical analysis of the worst possible case indicates that heuristic algorithms are capable of producing poor solutions.
3. However, experience with some reasonably realistic data sets indicates that heuristic algorithms produce very close-to-optimal solutions in practice. For instance, a simple 1-for-1 interchange heuristic achieves the optimal solution in 2/3 of the sample problems and is never more than 3% away from the optimal solution in the remaining sample problems.

The Corneujols, Fisher and Nemhauser conclusions on the value of heuristic procedures versus optimization algorithms are further supported by test results obtained by Baker, Maier and Vander Weide [1]. These authors test a sequential heuristic procedure that obtains an initial solution from a dynamic programming algorithm and improves this initial solution with 1-for-1 and 2-for-2 interchanges of lockboxes not in the solution with those currently in the solution. In no case did this heuristic procedure fail to obtain the optimal solution.

As noted above, the authors have implemented solution procedures for the

TAW_R_COCDR1#80Attachment
Page 580 of 739

lockbox and disbursement location problems at over three dozen banks nationwide. We have generally recommended the use of the 1-for-1 and 2-for-2 interchange heuristics because they provide valuable information on both optimal and close-to-optimal solutions. However, we have also employed a Lagrangian Relaxation/Branch-and-Bound [22] procedure as a check on the heuristics. In the hundreds of studies we have done over the last seven years, we have never found a single instance in which the more elaborate optimization techniques found a superior solution to the heuristics.

The above results and experiences indicate that the literature's concern with algorithms has been misplaced. Given the errors in data noted earlier in this paper, minor differences in algorithms are insignificant, especially when experience has shown that fairly simple heuristics work just as well as the most sophisticated optimization techniques.

V. The Disbursement Bank Location Problem

The mathematical description of the Disbursement Location Problem is similar to that of the Lockbox Location Problem (See Maier and Vander Weide [21]). The major difference is that optimization occurs over both mail points and drawee bank locations. Despite this difference, the solution algorithms for the Disbursement Location Problem are not significantly more complex than those for the Lockbox Location Problem.

The published research on the Disbursement Location Problem is concerned primarily with model formulation. The original formulation appears in a paper by Shanker and Zoltners [25]. The Maier and Vander Weide [21], Gitman, Forrester and Forrester [12] and Ferguson and Maier [9] paper contain modifications of this original formulation.

VI. Data Requirements and Issues

To solve the Disbursement Location Problem, the analyst needs to divide the firm's vendors into homogenous groups; obtain data on the fixed and variable costs of maintaining a disbursement system, the mail times from regional offices to vendor groups, the presentation times from vendor groups to drawee banks, the mail and presentation times for the firm's current system and the average daily payments to vendor groups j; and find an efficient algorithm for evaluating the set of possible mail and drawee bank sites. Again the analyst must make important decisions at each stage of the analysis. In addition there are several problems with implementing solutions to the Disbursement Location Problem that are unlike any faced in implementing solutions to the Lockbox Location Problem.

6.1 *Maximizing Mail Times*

The original formulation [25] includes the possibility of maximizing mail times. This makes sense only if the recipient of a check uses the mail date to determine when an item is paid. This is by no means universal practice. A recent survey

(see Hill, et al. [13]) indicates that recipient firms use mail date less than 28% of the time. In addition, most firms are unwilling to incur the risk of vendor ill-will caused by mail time extension.

6.2 *Quality of Data*

Many of the same data issues that arise in the Lockbox Location Problem arise in the Disbursement Location Problem as well. First, the fixed and variable costs of setting up disbursement systems are hard to measure and the value of control and float extension far overshadows small cost differences that exist between banks. Moreover, as long as the payment system remains primarily paper based, the firm must write its checks on at least one bank. The elective feature of a lockbox is not a consideration when setting up a disbursement system.

Second, clearing time surveys are not nearly as accurate as the mail and availability time surveys used in the Lockbox Location Problem. This basic fuzziness of the database has discouraged analysis and made much of the existing analysis suspect. The major banks that do disbursing analysis report two to four times as many lockbox studies performed as disbursement studies. This fact is surprising when one considers that the disbursement problem is even more universally applicable than is the lockbox problem.

Finally, it should be noted that the same problems in defining homogeneous vendor groups exist here as they did the lockbox problem. Consequently, studies are performed in which vendors are grouped by states, zip codes and individually isolated. In addition, there is greater sophistication in handling individual vendors than in handling individual customers; some of the more advanced disbursement control systems assign individual vendors on a check-by-check basis.

6.3 *Federal Reserve Policies*

The solutions to the original formulation of the Disbursement Location Problem frequently produce an increase in "clearing system slippage." Clearing system slippage is defined as the difference between the clearing time experienced by the check writer and the availability time granted to the check depositor. The greater is this number, the greater the difficulty the clearing agent, principally the Federal Reserve, is having in moving checks through the system. It is argued that the Federal Reserve will concentrate on the points that have large slippage in its efforts to discourage remote disbursing and to reduce its own Federal Reserve float. Its activity in reducing Federal Reserve float has been very well publicized. In 1979 Fed float stood at 6.7 billion dollars on an average daily basis while in 1982 it has averaged less than 2 billion dollars per day.

An attempt to include in the analysis the risk that the Federal Reserve will further reduce clearing system slippage is described in Ferguson and Maier [10]. This paper suggests that the concept of the Efficient Frontier from Portfolio Theory can be applied to measure the risk/return trade-off faced by the corporate cash manager as he designs his disbursement system. Nine of the nation's leading cash management banks have adopted this technology as their consulting approach.

TAW_R_COCDR1#80Attachment
Page 582 of 739

6.4 *Vendor Ill Will*

Attempts to implement the solutions to the Disbursement Location Problem may lead to deteriorating relationships with the firm's vendors or creditors. More than one firm has found that its vendors refuse to grant a discount for prompt payment when it uses a remote disbursement location. In one celebrated case, Merrill Lynch was sued by customers who were unable to get prompt refunds from security transactions. (Merrill Lynch had a practice of paying East Coast customers with checks drawn on West Coast banks and West Coast customers with checks drawn on East Coast banks. *Wall Street Journal* December 18, 1978, p. 14).

6.5 *Credit Problems*

Remote cities such as Helena, Montana; Reno, Nevada; and Midland, Texas frequently appear in the solution to the Disbursement Location Problem. Unfortunately, these cities are not always well suited as banking locations. For example, a firm will normally want its disbursing bank to be part of its credit group. This is because if for any reason there is a failure to fund the disbursing account, the disbursement bank can use its already preauthorized credit lines to extent credit to the firm and not have to return the items marked "insufficient funds", a situation most companies would consider unacceptable. However, banks are restricted by the Federal Reserve to lend no more than 10% of their equity capital to any one customer. Since banks in cities such as Helena and Reno have a small equity base, they cannot extend sufficient credit to fund the disbursements of large firms.

VII. Conclusions

If there is a lesson to be learned from our experiences with lockbox and disbursement models, it is that the existing academic literature has been very misleading as to the true state of the art in this area. Perhaps the two most significant issues we have addressed in this paper are the importance of data and the over simplicity of the mathematical formulations.

The most important change in the lockbox design area over the past five years is the improvement in the precision of supporting databases. In particular, the evolution from mail time only to mail and bank availability analysis has had very major ramifications in the industry. The sensitivity of the problem to how customers are grouped and even the quality of the receivable sample cannot be overemphasized.

The simple model of the lockbox problem as originally proposed by Levy falls far short of the practical requirements of designing lockbox systems. What does one do in a multidivision environment? What happens if your customer base significantly uses remote disbursing? How do you incorporate seasonality? What happens if your collections are dominated by a few large items received on only a sporadic basis? These are some of the questions that must be and are addressed in practice.

The academic literature on the disbursement location problem has failed to

fully recognize the complexity of this problem. True, float is important. But so is control. Moreover, the environment today is so unpredictable that neither float nor control can be obtained without significant system risk in the form of instability.

In summary, the lockbox and disbursement problems remain two of the most widely applied management science models in the finance area. Unfortunately, the existing literature on these problems has been misleading on the issues that are really important to the practitioners who actually implement solutions.

ON THE DECENTRALIZED CAPITAL BUDGETING PROBLEM UNDER UNCERTAINTY*

BØRGE OBEL† AND JAMES VANDER WEIDE‡

This paper deals with decentralized capital budgeting problems when decision objectives are not necessarily identical with those of corporate headquarters.

This paper extends previous analysis of this problem to the case where (i) the cash flows resulting from managerial actions are uncertain, (ii) division managers have nonlinear utility functions which differ from those of top management with respect to risk aversion and (iii) resource constraints may be nonlinear. Several realistic considerations arise in this context which were absent in previous analyses. First, because the division managers' utility functions reflect differing attitudes toward risk, top management has the opportunity to share some business risk with the division managers. We recommend a transfer pricing scheme that accounts for this possibility. Second, if the transfer prices for capital resources are state-dependent and the division managers make their investment decisions before the state of nature is revealed, the division managers will want to hedge against the additional uncertainty caused by this aspect of the problem. Despite the static nature of the analysis this paper raises the interesting problem of information flow within the firm and suggests ways to motivate division managers to act in the best interest of the firm. The transfer pricing algorithm has additional interesting applications.

(FINANCE–CAPITAL BUDGETING; FINANCE–MANAGEMENT)

1. Introduction

It is common practice in corporate finance theory to assume that all corporate decision makers seek to maximize the market value of the firm's equity, and hence that they all have identical objectives. When this assumption is combined with a perfect capital markets assumption, optimal capital budgeting rules in both the centralized and decentralized firm take an especially simple form. Each decision maker should be instructed to accept all capital projects with a positive present value at the market rate of interest.[1]

Carleton, Kendall and Tandon [2] and Maier and Vander Weide [11] have recently proposed formulations of the decentralized capital budgeting problem which are more consistent with the common corporate practice of using both budgets and discount factors to allocate resources to the firm's divisions. A fundamental assumption of these analyses is that capital markets are imperfect in the sense that the supply price of capital depends on the amount of capital used. Additional assumptions are that all cash flows are known with certainty and the division managers have the same linear utility functions as top management. Since many practical problems in decentralized capital budgeting occur only under conditions of uncertainty and non-identical utility functions, it is important to examine whether the results of [2] and [11] can be extended to more realistic environments.

The Carleton, Kendall and Tandon paper describes capital budgeting in the decentralized firm as a two-step process. Top management uses a "macro" model in

†Odense University.

‡Duke University.

[1]Those finance theorists who utilize the capital asset pricing model (see e.g. [16]) would probably recommend that the discount rate be determined by the capital market line rather than by the company's cost of capital. This advice too, however, is at variance with the usual corporate practice of using both budgets and discount factors to allocate funds within the firm. One purpose of this paper is to shed light on the circumstances under which current practice is acceptable, at least in spirit.

the first step to determine optimal levels for such corporate variables as dividends, debt and equity financing, investment in working capital and total capital expenditures. Once the firm's "macro" variables are determined, top management allocates a fixed capital budget among the corporate divisions, where decisions are made regarding the particular projects to be accepted. Because the division demands for capital are interrelated through the financial constraints of the "macro" model, it is important in the second step that the headquarters determine the appropriate transfer price for capital resources. The Carleton, Kendall and Tandon paper suggests a mechanism, the Dantzig-Wolfe decomposition algorithm, by which correct transfer prices can be found.

Maier and Vander Weide have modeled the capital budgeting problem in the decentralized firm as a single step process in which optimal budgets and transfer prices are determined simultaneously. When both budgets and transfer prices are used as coordination devices in the Dantzig-Wolfe algorithm, Maier and Vander Weide show that "(i) the decomposition algorithm does indeed converge to an optimal corporate solution, (ii) under reasonable assumptions, the marginal rate of return on the last dollar spent is the same for each division and is equal to the corporate headquarters' 'marginal cost of capital', (iii) in some circumstances the decomposition model will only select integral projects, and (iv) the optimal choice of projects for the firm is made independently by the divisions, each acting in its own self-interest."[2] The Maier–Vander Weide paper thus offers a further justification for current corporate budgeting practice.

In this paper, we extend the analysis of the decentralized capital budgeting problem to the case where (i) the cash flows resulting from managerial actions are not known with certainty, (ii) division managers may have nonlinear utility functions which differ from those of top management with respect to risk aversion and (iii) resource constraints may be nonlinear. Several realistic considerations arise in this context which were absent in the previous analyses. First, because the division managers' utility functions may reflect differing attitudes toward risk, top management may have the opportunity to share some business risk with the division managers. An optimal transfer pricing scheme should account for this possibility. Second, it now becomes important to specify exactly the flow of information between top management and the division managers. If the transfer prices for capital resources are state-dependent and the division managers make their investment decisions before the state of nature is revealed, the division managers may want to hedge against the additional uncertainty caused by this aspect of the problem. We see below that this is indeed true.

Because the formulation of the decentralized capital budgeting problem under uncertainty is sensitive to assumptions regarding the decision environment, we present several formulations of the problem. The first formulation is contained in §2, where we assume that (i) the headquarters wishes to maximize a convex combination of the division utility functions, (ii) all decision variables are state-independent, i.e., decisions are made before the state of nature is known and (iii) the prices for internal capital resources are state-independent, and are known with certainty before division capital investment decisions are made. The implications of relaxing these assumptions are discussed in §3. The fourth section contains a discussion of alternative coordination mechanisms which the headquarters might employ to induce the division managers to act in the best interests of the firm.

Although we have chosen to interpret the results of this paper as a generalization of the decentralized capital budgeting problem under certainty, some readers may be interested to know that other interpretations are also possible. If the headquarters in

Page 589 of 739

the models to follow is identified with the auctioneer in a perfectly competitive capital market and the divisions are identified with individual financial institutions, then our results can be interpreted as being a generalization of the linear capital market network models studied by Boyer, Storoy and Thore [1]. The results may be similarly related to other problems of decentralized decision making, such as the agency problem of Ross [13], the performance evaluation problem considered by Kriebel and Lave [10] and Demski [4], the divisionalized transfer pricing problem studied by Hirshleifer [5] and Ronen and McKinney [12], the resource allocation models of Jennergren [7], and the interesting models of Wilson [17] on the formation of syndicates. To the best of our knowledge, our paper is unique in that it creates an iterative transfer pricing scheme for several of the above problems which applies to situations of uncertainty, nonlinear utility functions, goal conflicts and nonlinear constraints.

2. Problem Formulation and Solution

For clarity of presentation, we shall discuss our decentralized capital budgeting problem using the model of a firm allocating a fixed capital budget, a, to n sets of investment projects, labelled $j = 1, \ldots, n$.[3] The amount which the firm invests in the projects of set j is given by the elements of a vector x_j. Let $G_j^s(x_j)$ be the amount of capital used by the projects of set j in state of nature $s \in S$ and let $g_j^s(x_j) \leqslant 0$ represent additional constraints on the firm's investment choices. The additional constraints might represent physical limitations on the firm's productive resources. If we assume that the firm's utility function for all of the projects is the sum of the utilities for each set j, then the firm's capital budgeting problem can be formulated as the following mathematical program:[4,5]

Problem I

$$\text{Maximize} \sum_{j=1}^{n} \int_S U_j^s(x_j)\, dP(s)$$

with respect to $x_1, \ldots, x_n$; $a_1, \ldots, a_n$

$$\begin{aligned} \text{subject to} \quad & \sum_{j=1}^{n} a_j \leqslant a, \\ & G_j^s(x_j) \leqslant a_j \qquad \forall s \in S; j = 1, \ldots, n, \\ & g_j^s(x_j) \leqslant 0 \qquad \forall s \in S; j = 1, \ldots, n, \end{aligned}$$

where a_j is the amount of capital allocated to investment set j, $U_j^s(x_j)$ is the utility which the firm derives from the investments j in state s and $P(s)$ is the probability distribution function over $s \in S$. The $\int_S U_j^s(x_j)\, dP(s)$ is thus the expected utility from the projects in set j.

[3] Our model would have been more realistic if we had allowed the headquarters to borrow and lend in the external capital markets at different rates, r_B and $r_L < r_B$, and allowed decisions to be made at more than one point in time. The addition of these realistic elements to the problem would complicate our notation substantially, while offering little extra insight. For this reason, we felt the decision to delete these elements would meet the approval of the reader.

[4] We assume that Problem I is a concave/convex problem, and that it has an optimal solution. We furthermore assume that the feasible set for each division is bounded. Neither of these assumptions is restrictive for the conclusions made in the paper.

[5] In this formulation we have assumed that the utility function is separable. This is not a restriction on the use of the Dantzig-Wolfe decomposition algorithm, but in the nonseparable case the information flow is a little more complex. (See Holloway [6] for details.)

TAW_R_GOOGLE_1480_Attachment
Page 190 of 738

We assumed in our formulation of Problem I that the firm had identified n sets of investment projects, each physically independent of the others. In reality, these sets of projects might be located in different geographical regions of the country, or they might be associated with the firm's various product lines. When attempting to solve Problem I, the firm will likely recognize the high cost of obtaining adequate information about the investments in each set j. The firm can reduce its information costs substantially by delegating decision making authority regarding each x_j to n division managers. The decentralization of decision making authority, however, will also raise some problems for top management.

One problem arises because the division managers are not likely to have goals which coincide with those of the corporate headquarters. To solve this problem top management must find some coordination mechanism which will induce unanimity among division managers and the headquarters regarding the optimal solution to the capital budgeting problem. An equally serious problem arises because of the presence of common capital constraints, which make the division managers' decisions interdependent. The coordination mechanism must therefore also induce the division managers to consider the corporate effects of their decisions.

In our discussion of the decentralized capital budgeting problem, it is helpful to decompose Problem I into a master problem and a division problem:

Master Problem I

$$\text{Maximize} \sum_{j=1}^{n} W_j(a_j)$$

with respect to $a_1, \ldots, a_n$

$$\text{subject to} \sum_{j=1}^{n} a_j = a$$

where $W_j(a_j)$ is the value of the optimal solution to division j's capital budgeting problem.

Division Problem I[6]

$$\text{Maximize} \int_S U_j^s(x_j)\, dP(s)$$

with respect to x_j

$$\text{subject to} \quad G_j^s(x_j) \leq a_j \quad \forall s \in S, \tag{1}$$

$$g_j^s(x_j) \leq 0 \quad \forall s \in S. \tag{2}$$

In the above formulation of the Division Problem, the division managers do not consider the effect of their decisions on the available supply of corporate funds. One way to induce division managers to account for this effect is for top management to charge a transfer price for the use of limited corporate resources. In the linear formulation of the decentralized capital budgeting problem under certainty, the correct transfer prices are determined with the aid of the Dantzig-Wolfe algorithm [3]. Recently, Holloway [6] extended the Dantzig-Wolfe method to a very general class of concave/convex models. We verify in the Appendix that Problem I is in that general

[6]We assume throughout our discussion of the division problem that all participants have identical probability distributions over states of nature. The analysis in the more general case of non-identical probability distributions is essentially the same as that described below, except that a subscript j is attached to $P(s)$ wherever it appears.

Reproduced with permission of the copyright owner. Further reproduction prohibited without permission.

class. We can therefore use Holloway's approach to solve the transfer pricing problem.[7]

TAW_R_COCDR1#80Attachment
Page 591 of 739

If transfer prices are charged for the use of coporate funds, Division Problem I becomes Division Problem II:

Division Problem II

$$\text{Maximize} \int_S (U_j^s(x_j) - \pi a_j)\, dP(s)$$

with respect to x_j, a_j

$$\text{subject to} \quad G_j^s(x_j) \leqslant a_j \quad \forall s \in S,$$
$$g_j^s(x_j) \leqslant 0 \quad \forall s \in S,$$

where π is the transfer price which the headquarters charges for each dollar used of corporate funds.

Because the presence of common corporate constraints causes the division actions to be interdependent, it is important that top management sets transfer prices which will induce division managers to consider the corporate effects of their decisions. The headquarters coordinates the activities of the various divisions and determines the appropriate transfer prices at iteration t from the solution to the following Master Problem:

Master Problem II

$$\text{Maximize} \sum_{j=1}^{n} \sum_{i=1}^{t} \lambda_j^i \cdot \int_S U_j^s(x_j^i)\, dP(s)$$

with respect to $\lambda_1^1, \ldots, \lambda_j^i, \ldots, \lambda_n^t$

$$\text{subject to} \quad \sum_{j=1}^{n} \sum_{i=1}^{t} \lambda_j^i a_j^i \leqslant a,$$
$$\sum_{i=1}^{t} \lambda_j^i = 1, \qquad j = 1, \ldots, n, \tag{3}$$
$$\lambda_j^i \geqslant 0, \qquad j = 1, \ldots, n; i = 1, \ldots, t,$$

where λ_j^i is a weight applied to the ith proposed solution to division j's capital budgeting problem.

The capital budgeting process proceeds in the following fashion. The headquarters announces the transfer price π on corporate funds a. Each division is then asked how much of the capital resources it wants to use, given that it must pay π for the use of each dollar. It is worth emphasizing that each division's need for capital resources in the ith iteration of the capital budgeting process, a_j^i, is state independent. This means that, given the choice of projects, a_j^i is the minimal amount of capital resources such that the capital requirements will exceed a_j^i in no state of nature. The resources that each division requests are determined by solving Division Problem II. After solving Division Problem II each division submits to the corporate headquarters (i) the state independent need for capital resources, a_j^i, and (ii) the average utility obtained, $\int_S U_j^s(x_j^i)\, dP(s)$, where x_j^i is an optimal solution to Division Problem II during the ith

[7] A linear version of the Dantzig-Wolfe decomposition algorithm under uncertainty was presented in Jennergren [7]. Our transfer pricing scheme is thus a generalization of Jennergren's.

Page 592 of 739

iteration of the capital budgeting process. Using this information, the headquarters solves Master Problem II and obtains transfer prices as the dual value to constraint (3) in that problem. The procedure continues in this fashion until the prices do not change.

3. Alternative Formulations

The decentralized capital budgeting problem was analyzed above under the assumptions (i) the headquarters wishes to maximize a convex combination of the division utility functions, (ii) division decisions are made before the state of nature is known and (iii) transfer prices are state independent. We now see how the capital budgeting process changes when these assumptions are relaxed.

A. Goal Conflicts

It is common in finance theory to assume that all decision-makers wish to maximize the market value of the firm, and hence that they all have a common objective. The literature of organization theory indicates that this assumption may be unrealistic, especially in the multi-division firm. We now assume that the division manager uses a utility function $R_j^s(\cdot) \neq U_j^s(\cdot)$.[8] Such behavior on the part of the division manager may lead to a nonoptimal allocation of capital resources from the headquarter's point of view.

In the deterministic case, Kriebel and Lave [10] have shown that profit sharing together with a transfer-price system will induce the division managers to act in the best interests of the firm (assuming that the optimal transfer price can be found). But, because division utility functions now reflect attitudes toward risk, and the transfer price is determined in an iterative fashion,[9] this result does not carry over to the case where uncertainty is present. The question that arises then is this: can the transfer-price system be altered in such a way that the profit sharing rule[10] will give the optimal allocations of the capital resources, even if there is a difference in the division utility functions? We show that the answer to this question is "yes".

For the case where transfer prices are state independent, headquarters wants to find a price $\tilde{\pi}$ such that

$$\int_S \left[U_j^s(x_j) - \pi \cdot a_j \right] dP(s) = \int_S \left[R_j^s(x_j) - \tilde{\pi}_j \cdot a_j \right] dP(s)$$

or

$$\int_S \tilde{\pi}_j \cdot a_j \, dP(s) = \int_S \left[R_j^s(x_j) - U_j^s(x_j) + \pi \cdot a_j \right] dP(s).$$

But these two integrals will be equal if

$$\tilde{\pi}_j = \pi + \left\{ \int_S \left[R_j^s(x_j) - U_j^s(x_j) \right] dP(s) \right\} \left(a_j^{-1} \right). \tag{4}$$

The transfer price given by (4) provides top management with an opportunity to share some of the uncertainty in the return from risky projects with division man-

[8] We continue to assume, however, that top management acts in the best interests of the firm's stockholders. Thus, $U_j^s(\cdot)$ is the utility function of both the firm's top management and its stockholders.

[9] In an iterative scheme, the division managers have the opportunity to send incorrect information to the corporate headquarters. The incorrect information may decrease the transfer prices and hence increase the division's profits (See Jennergren and Müller [8]).

[10] Profit sharing is a reward system which offers division managers a constant percent of company profits in addition to their base salary. When profit sharing is used and there is no uncertainty, the division manager's utility function is linear in company profits. Thus, decisions which maximize his utility also maximize corporate utility.

agers. Suppose that division manager j is highly averse to risk. Then for a given set of risky investments, $\int_S [R_j^s(x_j) \cdot U_j^s(x_j)]\, dP(s)$

LAW_R_COCDR1#80Attachment
Page 593 of 739

is very likely negative and a_j^{-1} is positive. To induce the division manager to accept the risky set of projects, x_j, top management must clearly increase the expected value of the division manager's reward from x_j. Under the assumptions of our model, the expected value of the division manager's reward can be increased simply by charging a lower transfer price for the capital used in x_j. Equation (4) tells top management exactly how much the transfer price should be reduced. Since the new transfer price depends on both the corporate allocation of capital to the division and the division allocation to projects, the transfer price is now a price function.

To determine the transfer price $\tilde{\pi}_j$, the headquarters must have information about the $R_j^s(\cdot)$ functions. Although the algorithm requires exact knowledge of these functions for optimal decisions, the transfer price expression (4) provides useful qualitative information if headquarters merely wants to improve its current transfer pricing scheme. If it is known, for instance, that division manager j always applies a "conservative" utility function to project selection decisions, then expression (4) indicates that top management should reduce the transfer price to this division manager for capital invested in risky projects. It can be shown that small adjustments of this nature to the transfer price π will improve the solution to the firm's capital budgeting problem.

B. State Dependent Division Decisions

It is conceivable that in many situations the capital allocations of the divisions could depend on which state of nature occurred. This situation is not very interesting in our model, since we have assumed for notational convenience a single period horizon. Under this assumption, making decisions after the state of nature is known amounts to decision making under certainty. Nonetheless, state dependent decisions can be easily accommodated in Problem I by treating the amounts allocated to projects by division j in state of nature s, x_j^s, as the basic decision variable. With this change in mind, the rest of the analysis remains as we have described it.

C. State Dependent Transfer Prices

Let us now change the assumption that transfer prices are known before the state of nature is revealed and allow them to depend on which state occurs.[11] The division and master problems change in the following way:

Division Problem IIa

$$\text{Maximize} \int_S \left[U_j^s(x_j) - \pi^s \cdot a_j \right] dP(s)$$

with respect to x_j, a_j

$$\text{subject to} \quad G_j^s(x_j) \leqslant a_j \qquad \forall s \in S,$$
$$g_j^s(x_j) \leqslant 0 \qquad \forall s \in S.$$

[11] Situations like this may arise in multi-national firms if the transfer price is fixed in terms of the headquarter's home currency. During the planning process, the division manager would not know the transfer price, in terms of his currency, which he actually will pay the headquarters.

Reproduced with permission of the copyright owner. Further reproduction prohibited without permission.

TAW_R_COGDR1#80Attachment
Page 394 of 438

$$\text{Maximize} \sum_{j=1}^{n} \sum_{i=1}^{t} \lambda_j^i \int_S U_j^s(x_j^i)\, dP(s)$$

with respect to $\lambda_1^1, \ldots, \lambda_j^i, \ldots, \lambda_n^t$

$$\text{subject to} \quad \sum_{j=1}^{n} \sum_{i=1}^{t} \lambda_j^i G_j^s(x_j^i) \leq a \qquad \forall s \in S,$$

$$\sum_{i=1}^{t} \lambda_j^i = 1; \qquad j = 1, \ldots, n,$$

$$\lambda_j^i \geq 0, \qquad j = 1, \ldots, n;\ i = 1, \ldots, t.$$

It is evident from these changes that the information flow from the headquarters becomes state-dependent prices on the capital resources. The information from the divisions becomes a state dependent need for capital resources, $G_j^s(x_j^i)$, and average utility $\int_S U_j^s(x_j^i)\, dP(s)$.

Because the state dependent transfer price interpretation of the decentralized capital budgeting problem, like the state independent transfer price interpretation, originates in Problem I, and Holloway's extension of the Dantzig-Wolfe algorithm continues to apply, we have the following obvious proposition:

PROPOSITION I. *The optimal solutions in both interpretations of the decentralized capital budgeting problem are identical and generate optimal solutions for Problem* I. *Moreover,* $\pi = \int_S \pi^s\, dP(s)$ *is an optimal dual value for the capital constraints in Problem* I.

It follows from Proposition I that different assumptions about the state dependence of the transfer price do not influence the amount of resources that the divisions want. The amounts which the divisions allocate to individual projects, however, are dependent on whether the transfer price is determined before or after the state of nature is known.

4. Alternative Coordination Mechanisms

Instead of applying the Dantzig-Wolfe strategy for solving Problem I, a direct allocation strategy, such as the Kornai-Liptak method [9], the Ten Kate method [15] or the Silverman method [14], can be applied. When using one of these methods the headquarters, instead of determining prices of the capital resources, announces how much each division is allowed to use. The information submitted to the headquarters from the divisions is information derived from the dual variable of constraint (1) in Division Problem I. The actual information is dependent on the specific method used.

Again as in the price-directive approach the information may be state-dependent or not according to the interpretation of the dual variables of constraint (1) in the division problems as being prices which have to be paid before or after the state of nature is known.

5. Conclusion

Theoretical inquiry is most useful when it clearly establishes the extent and limitations of our knowledge. In this paper, we sought to extend the analysis of the decentralized capital budgeting problem to situations where investment cash flows are uncertain and division objectives are not necessarily identical with those of corporate headquarters. We found that an optimal transfer pricing scheme could be constructed

Reproduced with permission of the copyright owner. Further reproduction prohibited without permission.

FAW R.COCUR.#80Attachment
Page 595 of 739

in these situations, provided that the corporate headquarters had explicit knowledge of the division utility functions and probability assessments.

In addition, we suggest that the model provides important qualitative information even in situations where top management does not possess such explicit knowledge. If top management can determine whether manager j's utility function is either more conservative or more risky than its own, then the model indicates the direction in which current transfer prices should be changed. Small changes in this direction will lead to an improved solution to the corporate capital budgeting problem.

Appendix

In this appendix we show explicitly the steps of the Generalized Dantzig-Wolfe Approach (Holloway [6]) applied to our capital budgeting problem (Problem I). Additionally we show that the algorithm determines an optimal solution to Problem I.

Assume that $U_j^s(\cdot)$ is a concave function for all s and j, $G_j^s(\cdot)$ is a convex function for all s and j, and $(x_j \mid\mid g_j^s(x_j) \leq 0)$ is a compact and convex set for all s and j. Then, $\int_S U_j^s(x_j)\, dP(s)$ is a concave function and Problem I is a special case of the Canonical Problem in Holloway [6]. Therefore, all the results in Holloway's extension of the Dantzig-Wolfe approach can be applied directly to Problem I. Additionally, it is easily verified that, under the above assumptions, Master Problem I is a special case of Holloway's Canonical Problem as well, and the results of his paper can be applied to Master Problem I, too.

Therefore, the following algorithm leads to an optimal solution to Master Problem I, and hence to Problem I. (We assume that Problem I has a feasible solution).

Algorithm

Step 0. Determine for $j = 1, \ldots, n$ an a_j^1 such that

$$\left\{x_j \mid G_j^s(x_j) \leq a_j^1 \forall s \in S \text{ and } g_j^s(x_j) \leq 0 \ \forall s \in S\right\}$$

is nonempty. Set $t = 1$ and go to Step 1.

Step 1. Solve Master Problem II. Set V^t equal to the optimal solution value, and π^t equal to an optimal dual variable to constraint (3).

If $t > 1$ go to Step 2, otherwise go to Step 3.

Step 2. If $\pi^{t-1} = \pi^t$ then terminate. Otherwise go to Step 3.

Step 3. For $j = 1, \ldots, n$ solve Division Problem II with π equal to π^t. Let (x_j^{t+1}, a_j^{t+1}) be an optimal solution to this problem. Set $t = t + 1$ and go to Step 1.

This algorithm is well defined in the sense that, under the above assumptions, all the problems stated in the algorithm exist and have a finite optimal solution.

LEMMA *I*. *The algorithm converges monotonically.*

PROOF. In each iteration we add n columns to Master Problem II. This implies that $V^{t-1} \leq V^t \ \forall t$. Furthermore $V^t \leq \sum_{j=1}^n W_j(a_j^*) \ \forall t$ where $(a_1^*, \ldots, a_n^*)$ is an optimal solution to Master Problem I. This shows the lemma.

LEMMA *II*. *If* $\pi^{t-1} = \pi^t$, *then Master Problem* II *determines an optimal solution to Master Problem* I.

PROOF. Let $(\lambda_1^1, \ldots, \lambda_j^i, \ldots, \lambda_n^t)$ be an optimal solution to Master Problem II at iteration t. Since $\pi^{t-1} = \pi^t$, $\sum_{i=1}^t \lambda_j^i a_j^i$ is a part of an optimal solution to Division Problem II with π equal to π^t. Assume that

$$\left(\sum_{i=1}^t \lambda_1^i a_1^i, \ldots, \sum_{i=1}^t \lambda_n^i a_n^i\right)$$

Reproduced with permission of the copyright owner. Further reproduction prohibited without permission.

TAW_RI_DOCDR1#8_Attachment1
Page 596 of 739

is *not* an optimal solution to Master Problem I. Let $(x_1^*, \ldots, x_n^*, a_1^*, \ldots, a_n^*)$ be an optimal solution to Problem I. Then $(a_1^*, \ldots, a_n^*)$ is an optimal solution to Master Problem I.

$$\pi^t \in -\partial V^t\left(\sum_{j=1}^{n}\sum_{i=1}^{t}\lambda_j^i a_j^i\right)$$

(subgradient). This implies that

$$V^t\left(\sum_{j=1}^{n} a_j^*\right) < V^t\left(\sum_{j=1}^{n}\sum_{i=1}^{t}\lambda_j^i a_j^i\right) - \pi^t\left(\sum_{j=1}^{n}\sum_{i=1}^{n}\lambda_j^i a_j^i - \sum_{j=1}^{n} a_j^*\right)$$

(the subgradient inequality). The assumption that

$$\left(\sum_{i=1}^{t}\lambda_1^i a_1^i, \ldots, \sum_{i=1}^{t}\lambda_n^i a_n^i\right)$$

is not an optimal solution to Master Problem I and the above inequality implies that

$$\pi^t \sum_{j=1}^{n} a_j^* < \pi^t \sum_{j=1}^{n}\sum_{i=1}^{t}\lambda_j^i a_j^i.$$

This establishes that

$$\sum_{j=1}^{n} W_j(a_j^*) - \pi^t \sum_{j=1}^{n} a_j^* > \sum_{j=1}^{n} W_j\left(\sum_{i=1}^{t}\lambda_j^i a_j^i\right) - \pi^t \sum_{i=1}^{t}\lambda_j^i a_j^i$$

which implies that there exists a j^* so that

$$W_j^*(a_{j^*}^*) - \pi^t a_{j^*}^* > W_j^*\left(\sum_{i=1}^{t}\lambda_{j^*}^i a_{j^*}^i\right) - \pi^t \sum_{i=1}^{t}\lambda_{j^*}^i a_{j^*}^i.$$

This contradicts the assumption that $\sum_{i=1}^{t}\lambda_{j^*}^i a_{j^*}^i$ is a part of an optimal solution to Division Problem II, and the lemma is proven.[12]

A Note on the Optimal Investment Policy of the Regulated Firm

DAVID W. PETERSON AND JAMES H. VANDER WEIDE*

A fundamental issue in the field of regulatory economics is whether or not rate-of-return regulation induces the profit-maximizing regulated firm to overinvest in capital equipment. Although there has been much academic analysis of this issue, most of it has occurred within the confines of static economic models [2, 3, 16]. In this note, we examine the optimal investment policy of the regulated firm in a dynamic context characterized by the presence of adjustment costs for capital inputs. Models of this type have been considered by Eisner and Strotz [4], Lucas [8], Gould [6], and Treadway [14], in the study of the investment policies of an unregulated firm.

The major conclusion of our analysis is that the regulated firm may in some circumstances invest at a rate which is less at each instant of time than the investment rate chosen by a similarly situated unregulated firm. This conclusion is contrary to the commonly held belief that rate-of-return regulated firms always overinvest [1,[1] 7, 13, 15].

The optimal investment policy of the profit-maximizing unregulated firm is reviewed in Section I of this note. Section II contains a discussion of the effect of rate-of-return regulation on the optimal investment policy of the regulated firm. An example of a situation where the regulated firm always invests at a rate less than the unregulated firm is presented in Section III. The last section contains concluding comments.

I. The Optimal Investment Policy of the Unregulated Firm

We choose for our discussion of the unregulated firm's optimal investment policy a simple dynamic economic setting. With regard to the firm's production and revenue possibilities, we assume that the unregulated firm produces a single homogenous output (in the amount Q) in accordance with a production function $Q(K, L)$ which is continuous and nonnegative for nonnegative values of physical capital (K) and labor (L). We assume further that for positive K and L, Q is differentiable and that $Q(0, L) = 0 = Q(K, 0)$. The price P which the firm receives for its output is assumed to vary with the quantity Q produced as $P(Q)$, a nonnegative monotone decreasing differentiable function defined for $Q > 0$. The firm's revenues are then determined by the function

$$G(K, L) = P(Q)Q(K, L) .$$

We further assume that G is concave for $K, L \geqslant 0$, that $G(K, 0) = 0 = G(0, L)$, and that for positive K and L, G is strictly concave in L.

An essential distinction between the inputs labor and capital is captured by the assumptions regarding their acquisition costs. Labor is assumed to be a perfectly variable input which can be purchased in a competitive market at a constant price w. The total cost of labor per unit time is thus wL. Capital, on the other hand, is imperfectly variable in the sense that there are internal costs associated with new purchases. Alternatively, or in addition, capital is assumed to be purchased in an imperfectly competitive input market. In either case, the total cost of physical capital depends on the rate I of investment, and is given by the function

$$C = C(I)$$

with

$$C(I) > 0, C'(I) > 0, C''(I) > 0 \text{ for } I > 0$$

*Duke University. The authors are indebted to David Dayan, Elizabeth Bailey, E. E. Zajac, William Baumol, Francis Tapon, Wesley Magat, and at least one referee for their helpful comments on earlier versions of this note.

[1] For discussions of this paper see also [5] and [12].

TAW_R_COCDR1#80Attachment
Page 599 of 739

and $C(0) = 0 = C'(0)$.[2]

Under these assumptions the unregulated profit-maximizing firm's input choice problem can be stated mathematically as

Problem I:

Maximize $\int_0^\infty [G(K, L) - wL - C(I)]\, e^{-\delta t} dt$
with respect to I, L
subject to $\dot{K} = I - \alpha K$,
$K(0)$ given
$I \geqq 0, L \geqq 0$,

where $\delta > 0$ is the discount rate and $\alpha > 0$ is the rate of depreciation of the firm's capital stock. The Pontryagin [11] necessary conditions (which in the cases considered in this note are also sufficient) yield directly[3]

$$\lambda(t) = C'(I), \tag{1}$$

$$\dot{\lambda}(t) = -G_K + (\delta + \alpha)\lambda(t), \quad \lim_{t\to\infty} \lambda(t) e^{-\delta t} = 0, \tag{2}$$

$$\dot{K} = I - \alpha K, K(0) \text{ given}, \tag{3}$$

$$G_L = w, \tag{4}$$

where $\lambda(t)$ is the auxiliary function associated with the Hamiltonian.

An interesting economic interpretation of the firm's optimal investment policy can be obtained by solving the first-order differential equation (2) for λ:

$$\lambda^u(t) = \int_t^\infty G_K e^{-(\delta + \alpha)(\tau - t)} d\tau. \tag{5}$$

(The superscript u indicates the association with the unregulated firm). The expression on the right of (5) is the present value of the future marginal revenue products resulting from the firm's investment expenditures. Substituting this expression for λ into equation (1), we see that the optimal value of investment expenditures is found by equating this present value to the marginal acquisition cost of capital:

$$\int_t^\infty G_K e^{-(\delta + \alpha)(\tau - t)} d\tau = C'(I^u). \tag{6}$$

Note that the assumption $C''(I) > 0$ ensures a unique solution, I^u.

II. The Optimal Investment Policy of the Regulated Firm

The dynamic behavior of the profit-maximizing regulated firm can be compared meaningfully to that of the unregulated firm if the two firms operate in economic environments which are similar except for the presence of the regulatory constraint. Thus, we retain the assumptions of the previous section concerning the production function $Q(K, L)$, the revenue function $G(K, L)$, the labor cost w, and the adjustment costs for capital additions $C(I)$.

It is now assumed that the firm is subject to regulation of a form which requires the firm's rate-of-return on its capital base to be less than or equal to a prescribed value s' at all times, i.e., it is required that

[2] The assumption that $C'(0) = 0$ is not necessary for the most important of our conclusions, but it simplifies our argument in several places. It is not essential that L represent only labor costs and K only capital costs. Any of several variable inputs might be identified with L, one example being the fuel utilized by an electric power company. Similarly, if much of the effort of the labor force is devoted to the development of physical capital, as with telephone installers, such labor is better identified with a portion of I.

[3] More precisely, these conditions characterize the functions I and L defined as follows. Let T be a large positive number, and $I_T(t)$ and $L_T(t)$ be the functions which maximize the integral in Problem I taken over the interval $[0, T]$. If $I(t)$ and $L(t)$ are the limiting functions for $I_T(t)$ and $L_T(t)$ as $T \to \infty$, the functions I and L are characterized by conditions (1) – (4). Being limits of functions optimal over a finite but long time period, I and L may differ in certain pathological cases from their counterparts in the infinite horizon problem. We maintain, however, that of more interest to the economist than the infinite horizon problem is that in which the horizon is taken to be finite, albeit distant: We have taken it to be sufficiently distant that its exact numerical value exerts no influence on the solution. Our analysis of Problem II should be interpreted similarly; we seek the limit of the solutions to a sequence of versions of Problem II in which the horizon is finite but increasing beyond bound.

TAW_R_COCDR1#80Attachment
Page 600 of 739

$$\frac{G(K, L) - wL - \alpha\gamma K}{\gamma K} \leqslant s'$$

where

γ = a factor approved by the regulatory authority which transforms physical units into dollar units,[4] and

s' = the rate-of-return allowed by the authority.

For the purposes of the ensuing discussion, it is useful to rewrite the constraint as

$$G(K, L) - wL - sK \leqslant 0\,, \qquad (7)$$

where $s = \gamma(\alpha + s')$.

Under these assumptions, the regulated firm's input selection problem can be formulated mathematically as:

Problem II:

Maximize $\int_0^\infty [G(K, L) - wL - C(I)]\, e^{-\delta t} dt$

with respect to I, L

subject to $\dot{K} = I - \alpha K$,
$G(K, L) - wL - sK \leqslant 0$,
$K(0)$ given,
$I \geqslant 0, L \geqslant 0$.

Since G is a continuous concave function, the set S of (K, L) for which

$$G(K, L) - wL - sK \geqslant 0$$

is a nonempty, closed, convex set. Denote by $\bar{K}$ the largest value of K present in the elements of S, setting $\bar{K} = \infty$ if necessary. We assume $\bar{K} > 0$. If $\bar{K}$ is finite, $G(\bar{K}, L)$ is strictly concave in L and so there is a unique $\bar{L}$ such that $(\bar{K}, \bar{L}) \in S$. Furthermore, $(\bar{K}, \bar{L})$ is on the boundary of S and hence satisfies the regulatory constraint. If $\bar{K} = \infty$, we set $\bar{L} = \infty$. We call $(\bar{K}, \bar{L})$ the Averch-Johnson (A-J) point.

If at some instant t, $K(t) \leqslant \bar{K}$, the best value $L(t)$ of L to accompany $K(t)$ is one for which (7) is satisfied with equality. This is evident from the fact that L can be adjusted instantaneously and costlessly to any level and from the equation

$$\text{integrand}\,(K(t), L(t)) = [G(K(t), L(t)) - wL(t) - C(I)]\, e^{-\delta t} \geqslant [G(K(t), L) - wL - C(I)]\, e^{-\delta t} = \text{integrand}\,(K(t), L)\,,$$

which holds for all L satisfying (7). Hence, for $K \leqslant \bar{K}$, we may assume (7) to hold with equality. For each $K \in (0, \bar{K})$ there are two distinct values of L which satisfy (7) with equality, both of them optimal; the firm may choose one of them arbitrarily. If at some instant t, $K(t) > \bar{K}$, (7) is a strict inequality no matter what value of L is chosen.

The Pontryagin conditions for Problem II are[5]

$$\lambda = C'(I)\,, \qquad (8)$$

$$\dot{\lambda} = -G_K - \mu(t)(s - G_K) + (\delta + \alpha)\lambda, \qquad (9)$$

$$\lim_{t\to\infty} \lambda(t) e^{-\delta t} = 0\,,$$

$$\dot{K} = I - \alpha K,\ K(0) \text{ given}, \qquad (10)$$

$$(1 - \mu)(G_L - w) = 0\,, \qquad (11)$$

$$G(K, L) - wL - sK \leqslant 0, \mu \geqslant 0$$
$$\mu[G - wL - sK] = 0\,, \qquad (12)$$

where $\mu(t)$ is a multiplier associated with the rate-of-return constraint.

[4] There are several procedures for valuing the rate-base that can be characterized by the model rate-base-value = γK. The fair value method is consistent with this model if one assumes that the ratio between the fair value and the capital stock remains constant through time. The replacement cost method is also consistent with this model if one assumes that the *rate* of replacement is to be constant and independent of the amount of capital replaced. The historical cost method depends on the rate at which capital was acquired, as well as on the amount. According to Phillips [10, p. 241], "... twenty-six states use 'original cost'; two, 'prudent investment'; nineteen, 'fair value,' 'reasonable value,' or 'all elements considered'; one 'average net investment'; one, 'reproduction cost'; and one has not determined a method."

Page 601 of 739

Under mild assumptions, it can be shown that the regulated firm approaches some positive, finite asymptotic size $(\bar{K}^r, \bar{L}^r)$. Equations (8) – (12) indicate that $\bar{K}^r$ and $\bar{L}^r$ must satisfy

$$0 = -G_K - \mu(s - G_K) + (\delta + \alpha)C'(\alpha K)\,, \quad (13)$$

$$0 = (1 - \mu)(G_L - w)\,, \quad (14)$$
$$G \leqslant wL + sK,\ \mu \geqslant 0,\ \mu[G - wL - sK] = 0\,.$$

These are just the conditions necessary and sufficient for the solution of the problem

$$\text{Maximize} \quad G(K, L) - wL - \frac{(\delta + \alpha)C(\alpha K)}{\alpha} \quad (15)$$

with respect to $K, L \geqslant 0$

$$\text{subject to} \quad G \leqslant wL + sK\,. \quad (16)$$

Should it happen that $sK - (\delta + \alpha)C(\alpha K)/\alpha$ is maximized for some $\hat{K} \leqslant \bar{K}$, then $\bar{K}^r$ is just this maximizing value of K; otherwise $\bar{K}^r, \bar{L}^r$ maximizes (15) without regard to (16), and $\bar{K}^r > \bar{K}$. In case $K(0) \leqslant \bar{K}$, the solution to (9) is given by

$$\lambda^r = \int_t^\infty s e^{-(\delta + \alpha)(\tau - t)} d\tau$$

and the optimal investment policy is determined by the equation

$$\int_t^\infty s e^{-(\delta + \alpha)(\tau - t)} d\tau = C'(I^r)\,, \quad (17)$$

the superscript r denoting association with the regulated firm.

To interpret this equation, we recall that $s = \gamma(\alpha + s')$ is the steady stream of dollars per physical unit of capital which the firm is allowed to earn under the regulatory constraint. Thus, equation (17) requires that the firm equate the present value of the stream of dollar earnings resulting from its investment policy to the marginal acquisition cost of capital.

It is interesting to contrast for this case the investment policies of the regulated and unregulated firms. Comparing equation (17) with equation (6), and noting that $C'(I)$ is strictly monotonically increasing in I, we have

$$I^r \gtrless I^u \text{ as } \int_t^\infty s e^{-(\delta + \alpha)(\tau - t)} d\tau \gtrless \int_t^\infty G_K e^{-(\delta + \alpha)(\tau - t)} d\tau\,.$$

Since there is nothing in our model which constrains the values of the function G_K to be smaller than s, as was the case for the static models of Averch-Johnson and Takayama,[6] it is not surprising to find, as we do in Section III, that for some revenue functions the regulated firm will actually invest less than the unregulated firm.

An analysis of other properties of this model, including sensitivities to various parameter changes, is presented in [9].

III. An Example

Let

$$G(K, L) = (KL)^{1/2},\ C(I) = I^2\,.$$

The firm's optimal investment policy I^u is given by equation (6) which for this case is

$$\frac{1}{4w} \int_t^\infty e^{-(\delta + \alpha)(\tau - t)} d\tau = 2I^u(t)\,. \quad (18)$$

Consider the investment problem of the regulated firm whose revenue and cost functions are identical to those previously given, but which is constrained by the relation

$$K^{1/2}L^{1/2} - wL - sK \leqslant 0\,. \quad (19)$$

The reader can verify that the existence of a positive solution to the regulatory constraint (19) requires $4ws \leqslant 1$, which we now assume. It happens that $\bar{K}$, the largest value of K for which (19) is satisfied, is infinite. In accordance with the discussion in Section II, we may therefore assume that (19) holds with equality. The optimal investment policy for the regulated firm is determined by (17), which becomes

$$s\int_t^\infty e^{-(\delta + \alpha)(\tau - t)} d\tau = 2I^r(t)\,. \quad (20)$$

Hence, from (18) and (20),

[5] See footnote 3, supra.

[6] In these models $G_K = r$, the constant price of capital, and it is assumed at the outset that $r < s$.

TAW_R_COCDR1#80Attachment
Page 602 of 739

$$I^r = 4wsI^u \leqslant I^u .$$

Thus if s is chosen so that $4ws < 1$, the regulated firm invests at a rate below that of the unregulated firm, at every instant in time.

IV. Conclusions

We have demonstrated that, contrary to the spirit of much of the thinking based on the work of Averch and Johnson, it need not be true that rate-of-return regulation entices a firm to overinvest in productive capital. For a simple dynamic model featuring an imperfect capital market, we find that it may be optimal for the regulated firm to invest at every instant of time at a rate less than its unregulated counterpart. Our findings demonstrate once again the strong dependence on model specifications of the conclusions one draws in the study of regulatory problems.

A STRATEGY WHICH MAXIMIZES THE GEOMETRIC MEAN RETURN ON PORTFOLIO INVESTMENTS*

JAMES H. VANDER WEIDE†, DAVID W. PETERSON† AND STEVEN F. MAIER†

A common formulation of the portfolio selection problem leads to the prescription of a strategy which maximizes the geometric mean return on investments. In this paper we examine conditions under which solutions exist for the case where the returns distribution is discrete. We establish necessary and sufficient conditions for a solution to exist and give a computationally convenient and exact method for finding a solution in circumstances where (i) a solution exists and (ii) the number of securities equals or exceeds the number of values in the returns distribution.

1. Introduction

The geometric mean investment strategy, introduced into the finance and economics literature by Henry Latané [6] in 1959, has recently received some attention in scholarly circles after a decade of near neglect. Most of this work has been devoted to the investigation of various properties of the geometric mean strategy. Among the properties of optimal geometric-mean portfolios recently discovered are (i) they maximize the probability of exceeding a given wealth level in a fixed amount of time, (ii) they minimize the long-run probability of ruin, and (iii) they maximize the expected growth rate of wealth.[1] Relatively little attention has been given, on the other hand, to either the computational problem of finding the optimal geometric-mean portfolio[2] or the question of the existence of such a portfolio.[3] In this paper, we analyze both of these latter problems under various assumptions about the investor's opportunity set and the form of his subjective probability distribution of holding period returns. We reach two major conclusions. First, optimal geometric-mean portfolios do not exist for some rather obvious formulations of the investor's decision problem.[4] Second, optimal geometric-mean portfolios are in some circumstances more easily computed than was previously recognized.[5]

† Duke University.

[1] For discussion and derivations of these properties see [2], [5], [6], [10], and [15].

[2] We know of only three or four papers which purport to discuss the computation of optimal geometric mean portfolios. The first, by Elton and Gruber [4], assumes that total portfolio returns are lognormally distributed. But the analytical circumstances under which this would occur seem rather limited, since lognormal security returns do not imply lognormal portfolio returns. The second, by Ziemba [17], discusses the problem and proposes nonlinear programming as a solution means. The third, by Ziemba, Parkan and Brooks-Hill [18], pertains to the problem in which returns are normally distributed. A possible fourth paper is Ziemba's [16], which discusses general approaches to solving optimization problems with stochastic objective functions.

[3] Cass and Stiglitz [3] give conditions for an optimal solution to exist for the case where the returns distribution is finite and the number of securities exactly equals the number of states in the returns distribution. Their result is a special case of our Theorem 1. Leland [7] gives a sufficient condition for a solution to exist, but assumes that there is no direction of recession which offers a nonnegative return for all states of nature. Bertsekas [1] strengthens Leland's result by extending it to a more general class of utility functions and shows that for this class it can be made both necessary and sufficient. Though Bertsekas' approach is applicable to the geometric mean problem, his theorems require some modification to account for the fact that the logarithmic utility function is defined only for positive values of its argument.

[4] Richard Roll [13] unwittingly formulates a version of the geometric-mean problem for which a solution is unlikely to exist.

[5] Mossin [10], for instance, says "The main disadvantage—at least at present—of the growth optimal policy as compared e.g., with the selection of an E, S efficient policy, is the formidable computational problem."

2. The Existence of Optimal Geometric-Mean Portfolios

Consider an investor faced with the repetitive problem of investing his wealth in some combination of m alternative investment opportunities. Suppose that the investor's objective is to maximize the geometric mean return on his wealth. If x_i denotes the fraction of his wealth the investor invests in opportunity i and $r_i \geqslant 0$ denotes the periodic payout, including return of principal, provided by opportunity i, then we may identify the task of finding the optimal allocation of wealth for the coming time period as that of solving the following mathematical programming problem:

$$\underset{x}{\text{Maximize}}\, E\{\log x^T r\} \quad \text{subject to} \quad x^T e = 1, \tag{1}$$

where $x = (x_1, \ldots, x_m)^T$, $r = (r_1, \ldots, r_m)^T$, $e = (1, \ldots, 1)^T$ and E is the expectation operator.

As with any mathematical programming problem, there is in connection with (1) not only the question of finding the best value for x, but also the question of whether a best value exists. A solution x^* is a finite m-vector which imparts maximal value to the objective function. We discuss the question of whether a solution exists for two particular cases of the geometric mean problem.

The General Case

The general case of the geometric mean problem is one which imposes no restrictions on the investor's subjective probability distribution of holding period returns. The existence of a solution to a general geometric mean problem can be assured by suitably bounding the set of wealth allocations considered feasible. For example, if to the general problem (1) there are appended the restrictions $x_i \geqslant b_i$, $i = 1, \ldots, m$, where the b_i are known, finite constants summing to 1 or less, there results the problem we call the Constrained General Problem (CGP). The CGP always has a solution, for it consists of the maximization of a continuous function over a nonempty compact set.

We refer to the case where the feasible set is unrestricted as the Unconstrained General Problem (UGP). The UGP has a solution in many circumstances, an important one being that in which the returns r_i are jointly distributed in accordance with a probability density function which is positive for all r_i combinations near zero; that is $P(r) > 0$ for all positive r satisfying $0 < r^T e < \delta$, where δ is a sufficiently small positive number.[6] One example of such a situation is that in which the logarithm of the return for the ith security is $\alpha_i + \beta_i I + \epsilon_i$, where α_i and β_i are constants particular to that security, I is a market index, and ϵ_i is an independent normal random variable. In such circumstances, if one or more of the x_i is negative, there is a positive probability that $x^T r < 0$. Hence any portfolio for which all $x_i \geqslant 0$ is at least as desirable, and one may as well append these constraints. But now a CGP results, and as noted previously, such problems have solutions.

The Discrete Case

In the event the r_i are discrete random variables which can assume a finite number n of combinations of values, the Unconstrained General Problem may be stated

[6] Suppose that for some $\delta > 0$, the probability measure P governing r assigns positive probability to all open subsets of $T = \{r > 0 \mid r^T e < \delta\}$. Then T is open and nonempty. If some component of x is negative, then the set $S = \{r > 0 \mid r^T x > 0\}$ is open and nonempty, and the intersection $S \cap T$ is open and nonempty. Evidently $P(S) \geqq P(S \cap T) > 0$, so such an x cannot be strictly preferred to any one with components all of which are nonnegative.

TAW_R_COCDR1#80Attachment
Page 606 of 739

equivalently as the following Unconstrained Discrete Problem (UDP):

$$\underset{x}{\text{Maximize}} \sum_{j=1}^{n} \left[P_j \log\left((x^T R)_j\right) \right], \quad \text{subject to} \quad x^T e = 1. \tag{2}$$

Nature, in this formulation, is capable of assuming any of the states $j = 1, \ldots, n$, and the probability she will assume the jth is denoted P_j. The values of the r_i, when Nature assumes the jth state, are denoted r_{ij}. The $m \times n$ matrix of r_{ij} values is denoted R and assumed known. One may consider the UDP as an original formulation of the myopic portfolio selection problem, as did Latané [6], or as an approximation to an Unconstrained General Problem such as (1) permitting other than discrete returns r_i. This latter view is taken in [8].

If there exists a finite and feasible vector x^* which imparts a maximal value to the objective function, then we say x^* is a solution to the UDP. The assertion that a solution exists precludes the possibility that the objective function can be made arbitrarily large, but does not preclude its being negatively infinite for all feasible vectors x, as would occur if one or more columns of R were all-zero. To avoid the latter possibility, we now assume that no column of R contains only zeroes.

The following theorem gives necessary and sufficient conditions that a solution to the UDP exists.

THEOREM 1. *The UDP has a solution if and only if there exists an $n \times 1$ vector y, all of whose components are positive, such that $Ry = e$, where e is the $m \times 1$ vector of ones.*

PROOF. Suppose there exists $y > 0$ such that $Ry = e$, and suppose x satisfies $x^T R \geqq 0$, $x^T e = 1$. Let $y_{\min}$ denote the component of y which is minimal, and note that $y_{\min} > 0$. Then $0 \leqq (x^T R)_j \leqq x^T R e \leqq x^T R y / y_{\min} = 1/y_{\min}$, hence the feasible region of $((x^T R)_1, \ldots, (x^T R)_n)$ values is bounded. Since the region is also closed, it is compact, and the objective function, being continuous on this set, assumes a finite maximum.

If there exists no $y > 0$ such that $Ry = e$, then there exists by Tucker's Theorem of the Alternative [9, p. 34] an x such that $x^T R \geqslant 0$, $x^T e = 0$.[7] Then $\alpha x + e/m$ is feasible and imparts to the objective function a value which can be made larger than any preassigned number by taking α sufficiently large. Hence, in such a situation, no solution to the UDP exists.

The condition $Ry = e, y > 0$, ensures the objective function assumes a maximal value for some choice of finite x_i's, though the set of x_i's imparting maximal value to the objective need not be bounded. If the condition fails to hold, then the feasible region is unbounded in such a way that one can make the objective function arbitrarily large by selling short one or more securities and buying others. A test of the condition can be implemented by using a linear programming code to find a feasible solution to $Ry = e, y \geqq \epsilon e$, for some small positive ϵ. A geometrical interpretation of the condition $Ry = e, y > 0$, is that e lies in the interior of the positive cone spanned by the columns of R.

The condition of Theorem 1 can be restated in equivalent form:

THEOREM 1′. *There exists no solution to the UDP if and only if there exists some x such that $x^T R \geqslant 0$ and $x^T e = 0$. (We use "$\geqslant$" to mean "$\geqq$ but not $=$".)*

[7] Tucker's Theorem of the Alternative, as given in [9, Table 2.4.1] yields the stated result if we set $B' = R$, $C = 0$, $D = e^T$, $x = x$, and $y_2 = y$, where the entities on the left of the equal signs appear in [9], and those on the right are our own symbols.

TAW_R_COCDR1#80Attachment
Page 607 of 739

PROOF.[8] Tucker's theorem of the alternative [9].
If x satisfies the condition of Theorem 1′, it has positive components summing to, say, $d > 0$, and negative components summing to $-d$. Denote by x^+ (x^-) the vector obtained by setting to zero the negative (positive) components of x. Then x^+/d and $x^-/(-d)$ are each nonnegative vectors whose components sum to 1, and may each be considered a portfolio specification. Furthermore, $(x^+ + x^-)^T R \geqslant 0$, so $(x^+/d)^T R \geqslant -(x^-/d)^T R$. Hence Theorem 1′ may be restated as, "*An infinite solution to the UDP exists if and only if some convex combination of securities dominates some other (disjoint) convex combination of securities for every state of nature.*" If an x satisfying the condition of Theorem 1′ is available, one can do arbitrarily well by letting the portfolio proportions be $\alpha x + e/m$, and making α a large number.

3. The Likelihood of the Existence of a Solution to the Unconstrained Discrete Problem

Having established exact circumstances under which the UDP has a solution, we examine next the likelihood with which these circumstances occur. In this regard, it is helpful to consider a special form of the returns distribution in which one security dominates all other securities for each state of nature. In addition, we will assume that for each state of nature all securities besides the dominant one have equal returns. Let a radial vector be defined as any m-component vector r which has nonnegative components, all of which are equal, save one which is greater than the rest. Let the n columns of R be radial vectors selected probabilistically in such a way that the probability the ith component exceeds the other components of the jth column vectors is $1/m$, $1 \leqq j \leqq n$, $1 \leqq i \leqq m$. For R to be such that there exists a $y > 0$ satisfying $Ry = e$, the columns of R must include at least one radial vector for which the first component is largest, one radial vector for which the second is largest, and so forth. This leads at once to the conclusion that *if the n columns of R are radial vectors (no matter how they are chosen) and if $n < m$, then there is no $y > 0$ such that $Ry = e$, and hence no solution to the UDP exists.* If $n \geqq m$ and the columns of R are chosen as described above, then there is some positive probability that a solution to the UDP exists, and that probability increases with increasing n. For $n = m$, it happens that the probability of a solution is $m!/m^m$, which equals $\frac{1}{2}$ for $m = 2$ and decreases rapidly with increasing m. For $n \geqq m$, the probability of a solution is

$$1 - \binom{m}{1}\left(\frac{m-1}{m}\right)^n + \binom{m}{2}\left(\frac{m-2}{m}\right)^n - \binom{m}{3}\left(\frac{m-3}{m}\right)^n + \cdots \pm \binom{m}{m-1}\left(\frac{1}{m}\right)^n,$$

which for m fixed increases toward 1 as n gets larger.

Using Monte-Carlo methods, we have shown in an unpublished study that even for more general types of R matrices, the likelihood of the existence of a solution to the UDP increases as the number n of states of nature increases.

4. Solution of the UDP

A solution to the Unconstrained Discrete Problem (2) can often be obtained with the aid of an efficient nonlinear programming algorithm. The authors report their experiences in solving geometric-mean portfolio problems with one particularly efficient nonlinear programming code in [8]. As we show below, however, if n does not exceed the number m of securities, it is often possible to obtain optimal allo-

[8] Theorem 1′ may also be obtained as a consequence of Rockafellar's Theorem 27.3 [12, p. 267] which asserts the nonexistence of a solution to be equivalent to the existence of a common direction of recession for the objective function and the feasible set.

TAW_R_COCDR1#80Attachment
Page 608 of 739

cations even more efficiently through the solution of a certain set of simultaneous linear equations. Throughout the discussion of these equations, we assume that (i) a solution to the UDP exists and (ii) the payout matrix R has rank n.

THEOREM 2. *If H is an $m \times n$ matrix such that $H^T R = I_n$, then x constitutes a solution to the UDP if and only if*

$$(x^T R)_j = P_j/(H^T e)_j, \qquad j = 1, \ldots, n. \tag{3}$$

PROOF. (Follows [14, pp. 77–78], with some modifications and extensions).

Necessity. By hypothesis, a solution $x^* = (x_1^*, \ldots, x_m^*)$ exists. Since $\operatorname{rank}(R) = n$, no column of R is 0, and so x^* imparts a finite (as opposed to negatively infinite) value to the objective function. Hence $x^{*T} R > 0$. Define the Lagrangian function

$$L(x) = \sum_{j=1}^{n} \left[P_j \log\left((x^T R)_j\right) \right] - \lambda e^T x.$$

It is necessary then that x^* satisfy

$$\nabla L(x^*) = Ry^* - \lambda e = 0, \tag{4}$$

$$x^{*T} e_m = 1, \tag{5}$$

where $y^* = (y_1^*, \ldots, y_n^*)^T$,

$$y_j^* = P_j/(x^{*T} R)_j, \qquad j = 1, \ldots, n, \tag{6}$$

and λ is a scalar constant.

Premultiplying (4) by x^{*T} and noting (5) and (6), we observe that $\lambda = 1$. By hypothesis, $\operatorname{rank}(R) = n$ so there exists (see Penrose [11]) an $m \times n$ matrix H such that $H^T R = I$. From (4), $y^* = H^T e$. Using this in (6) yields $(x^{*T} R)_j = P_j/(H^T e)_j$, and necessity has been established.

Sufficiency. Retrace the above steps, bearing in mind that a solution is presumed to exist, that $L(x)$ is concave, and that a saddle point sufficiency condition is applicable.

This theorem raises the exciting prospect that the UDP often can be solved through the solution of (3). The latter can be accomplished for fairly large R matrices using a standard linear programming computer code. Even more straightforward is the situation in which R is square and of full rank, for then Theorem 2 becomes:

COROLLARY. *If $\operatorname{rank}(R) = n = m$, let $H^T = R^{-1}$. Then the x that constitutes the unique solution to* (1) *is given by $x = R^{-1}\bar{P}$, where $\bar{P}_j = P_j/(R^{-1} e)_j$, $j = 1, \ldots, n$.*

The applicability of Theorem 2 is limited, unfortunately, by two elements of its hypothesis. The first of these is that the matrix R have rank n. Since R is of dimension $m \times n$, this restriction requires $m \geqslant n$, or equivalently that the number of securities exceed or equal the number of states of nature.

The second limiting element in the hypothesis of Theorem 2 is the assumption that a solution to the UDP exists. As is explained in the previous section, this is unlikely except in cases where n exceeds m or where the x_i are further constrained. With the imposition of additional constraints (such as nonnegativity), the development of a theorem analogous to Theorem 2 does not seem possible, and one is apparently forced to retreat to nonlinear programming codes to obtain numerical solutions.

EXAMPLE. The following example illustrates a situation where the results of the Corollary to Theorem 2 apply. Suppose that the returns on ten securities in each of ten states of nature are given by the following return matrix:

TAW_R_COCDR1#80Attachment

1.15	0.97	1.54	0.95	1.09	1.14	1.08	0.90	0.91	0.82	·
1.13	0.95	1.10	1.03	1.89	1.20	0.97	1.04	1.04	1.00	·
0.93	1.08	0.84	0.97	0.95	0.80	0.95	0.98	1.29	1.46	Security 10

In addition, suppose that the probability that each state of nature occurs is given by:

$$P_1 = 0.3, \quad P_2 = 0.15, \quad P_3 = 0.1, \quad P_4 = 0.1, \quad P_5 = 0.06,$$
$$P_6 = 0.06, \quad P_7 = 0.06, \quad P_8 = 0.06, \quad P_9 = 0.06, \quad P_{10} = 0.05.$$

Then, since $\text{rank}(R) = 10 = n = m$, the optimal amount to invest in each security is given by the Corollary to Theorem 2. Using this corollary, we have

$$x_1 = -0.857, \quad x_2 = 14.952, \quad x_3 = -0.244, \quad x_4 = 0.048, \quad x_5 = -1.284$$
$$x_6 = 3.666, \quad x_7 = 0.398, \quad x_8 = -6.759, \quad x_9 = 1.446, \quad x_{10} = -10.364.$$

With this highly unbalanced portfolio we would get an annual return of 66.2%.

5. Conclusion

Though much has been written about the desirable properties of growth-optimal portfolios, relatively little attention has been given to the problem of computing the wealth allocation necessary to achieve such a portfolio. This latter problem, with which the present paper is concerned, has two major aspects, one dealing with the existence of a solution, and the other with the numerical determination of a solution in those instances where a solution exists.

For a wealth allocation model called the Unconstrained General Problem (UGP) we show that there are circumstances under which a solution does not exist, and provide conditions sufficient to ensure that a solution does exist. For this general problem, in cases where a solution exists, it is suggested that recourse to a nonlinear programming code may be necessary to obtain a numerical solution.

A special case of the UGP is the Unconstrained Discrete Problem (UDP). For this problem too it is found that a solution need not exist, and that it probably does not exist in the case where the number of securities exceeds the number of possible states of nature. It is, unfortunately, just such a relationship between the numbers of securities and states of nature which permits a solution, if it exists, to be found readily as a solution to a set of simultaneous linear equations. In case the number of states of nature exceeds the number of securities, it is likely that a solution exists. In this case, though, it seems that a nonlinear programming code must be used to compute the solution, a task with which our experience is reported elsewhere [8].[9]

[9] The authors wish to acknowledge Professor Henry Latané's helpful insights, particularly in regard to the dominance characteristic associated with infinite solutions.

A MONTE CARLO INVESTIGATION OF CHARACTERISTICS OF OPTIMAL GEOMETRIC MEAN PORTFOLIOS

*Steven F. Maier, David W. Peterson, and James H. Vander Weide**

I. Introduction

The geometric mean investment strategy, introduced into the finance and economics literature by Henry Latane [7] in 1959, has recently received some attention in scholarly circles after a decade of near neglect. Perhaps the primary reason for the renewed interest in the "growth optimum" strategy was the discovery by Hakansson [5] and others [1], [6], [12] of several desirable properties of this strategy vis-a-vis other portfolio strategies, including the mean-variance efficient strategy. Among the properties of optimal geometric mean portfolios discovered by these investigators are (i) they maximize the probability of exceeding a given wealth level in a fixed amount of time; (ii) they minimize the long-run probability of ruin; (iii) they maximize the expected growth rate of wealth; (iv) they imply that myopic behavior is optimal; and, (v) they imply decreasing absolute risk aversion in wealth.

Despite these recent successes, many questions regarding the optimal geometric mean strategy remain unanswered. Among these are:

1. How many risky securities are contained in an optimal geometric mean portfolio under various assumptions about market conditions?
2. How does the availability of borrowing and lending opportunities affect the composition of the optimal geometric mean portfolio?
3. How well do heuristic portfolio building rules perform when compared to the optimal geometric mean portfolio?
4. What are the individual characteristics of securities contained in optimal geometric mean portfolios?

To answer these questions, we examined the solutions to a relatively large number of simulated geometric mean portfolio problems obtained with the aid of a numerically efficient nonlinear programming code imbedded within a partitioning

* *All, Duke University Graduate School of Business Administration.*

algorithm. Since the simulated portfolio problems contained many securities and the solutions were obtained in a reasonable amount of time,[1] we partially demonstrate as a by-product of our analysis the computational feasibility of the geometric mean approach to portfolio building.

Section II of this paper contains a formulation of the geometric mean portfolio problem, a discussion of both the solution methodology and the process from which we generated our ex-ante return data, and a description of several heuristic portfolio building rules used in our experiment. Discussions of the results of our experiments in both the case where borrowing is not permitted and the case where borrowing is permitted are contained in Sections III and IV, respectively. A summary of our major findings and some conclusions are contained in Section V.

II. Formulation and Methodology

Formulation. The i^{th} security or investment opportunity is postulated to have a holding period return h_i. This return is the ratio of the end-of-period selling price, plus accumulated interest and dividends, to the purchase price of a unit of the i^{th} security, and hence is a nonnegative number often in the vicinity of 1. The problem repeatedly solved in obtaining the conclusions reported herein is to find the optimal proportion x_i of given investment capital to invest in the i^{th} security, when one is faced with an array of one hundred possible securities, each of whose holding period return behavior is characterized by a probability density function which is assumed known. Stated mathematically, this problem is to

$$\text{Maximize } E[\log \sum_{i=1}^{100} x_i h_i]$$

$$\text{with respect to } x_1,\ldots,x_{100}$$

$$\text{subject to } x_i \geq 0,\ i=1,\ldots,100,$$

$$\sum_{i=1}^{100} x_i = 1.$$

For the case in which the h_i are lognormally distributed in a manner described

[1] A geometric mean portfolio problem with 100 securities and 50 states of nature was solved on average in 5 to 9 seconds CPU time on an IBM 370/165.

below, this is called the Formal Problem.

The Formal Problem was solved using a discrete probabilistic approximation technique which converts it to a Nonlinear Program of a form that is convenient for computer solution. Experimentally varying the degree of approximation, we chose a level that was efficient for computation yet faithful in reflecting the properties of the solution to the Formal Problem.

Solution Methodology. The Nonlinear Program was solved using a computer code developed by Gill and Murray [4]. This code was chosen both for its numerically stable characteristics and for its efficiency in solving concave programming problems having only linear constraints. A partitioning scheme was incorporated into the solution procedure to permit solution of portfolio problems with large numbers of securities, and to increase the efficiency of the algorithm. The first step in the solution procedure was to rank the securities by their individual geometric mean returns. Next, the Gill and Murray code was used to choose the best portfolio from among the highest-ranking securities; that is, all but the top 25 securities were forced to be in the solution to the Nonlinear Program at the zero level. Then the optimality of this solution was tested by computing the Kuhn-Tucker multipliers for the full set of securities, and checking whether the Kuhn-Tucker conditions for optimality were satisfied. (See [13] for the appropriate formulas.) If the solution satisfied the Kuhn-Tucker conditions, the program terminated, since this indicated the optimal solution to the Nonlinear Program for the full set of securities had been found. On the other hand, if the conditions were not satisfied, a new partition was constructed that consisted of all securities assigned positive proportions in the preceding iteration, all securities not in the partition which passed the Kuhn-Tucker test for inclusion, and as many additional securities as were permitted by the 25-security size constraint of the partition. The Gill-Murray code was then used to obtain a solution to this new partition and the Kuhn-Tucker multipliers were again used to test for optimality. In the over one hundred problems that were solved by this procedure, only in eight cases was it necessary to repartition the securities. In no case did this repartition fail to pass the subsequent optimality test.

Data Generation. The distribution of the holding period return h_i is assumed related to a market index I defined as the expected value over all securities of the logarithm of the holding period return. The return h_i of the i^{th} security is associated with I through the equation

$$\log h_i = \alpha_i + \beta_i I + \varepsilon_i, \tag{1}$$

where α_i and β_i are constants particular to the i^{th} security, ε_i is a normal random variable with mean zero and variance σ_i^2, and α_i, β_i and σ_i^2 are assumed known exactly. The index I is an indicator of the general market performance in the period to come, and is considered a normal random variable whose parameters are chosen subjectively by the investor.

Though one could use ex-post estimates for the one hundred $(\alpha_i, \beta_i, \sigma_i^2)$ triples and choose two parameters to reflect his beliefs about I, such a procedure for producing tables like those which follow (we have verified) could be very misleading. Our experience indicates, for example, that the number of securities in an optimal portfolio depends strongly on how similar the one hundred securities are, and that considerable care must therefore be taken to insure that the one hundred securities are typical of the market to which our conclusions are intended to pertain. To ensure that the values of the $(\alpha_i, \beta_i, \sigma_i^2)$ are chosen so they are a plausible representation of ex-ante beliefs about investment opportunities to be found on the major security exchanges, we have analyzed extensively a record of holding period returns for 381 securities over the nine-year period, 1963 to 1971.[2] This analysis leads us to the conclusion that picking a security at random from those listed on the New York Stock Exchange is analogous to picking an $(\alpha,\beta\ \sigma^2)$ triple under the governance of a trivariate normal distribution with the following parameters:[3]

$E(\alpha) = 0.0$ $\quad$ $Var(\alpha) = 1.225 \times 10^{-4}$

$E(\beta) = 1.000$ $\quad$ $Var(\beta) = 1.388 \times 10^{-1}$

$E(\sigma^2) = 1.339 \times 10^{-2}$ $\quad$ $Var(\sigma^2) = 6.644 \times 10^{-5}$

$cov(\alpha,\beta) = -3.195 \times 10^{-3}$ $\quad$ $cov(\alpha,\sigma^2) = -6.594 \times 10^{-5}$

$\quad$ $\quad$ $cov(\beta,\sigma^2) = 2.431 \times 10^{-3}$

The correlation matrix among these variables can be determined from the above data to be

---

[2]Data on these securities were made available to us by Henry Latane.

[3]The trivariate normal model is flawed for this purpose because it does not ascribe zero probability to events for which $\sigma^2 < 0$. This could be remedied by assuming that (α, β, σ) is trivariate normally distributed, but we chose (rather arbitrarily) not to do this.

(2)

	α	β	σ^2
α	1	-.775	-.731
β	-.775	1	+.801
σ^2	-.731	+.801	1

which is useful in rendering plausible some of the results that follow.[4]

To carry out our investigation, we drew one hundred independent samples from the above trivariate normal distribution and let these represent a like number of securities from which portfolios were to be constructed. These triples may be obtained from the authors. Values for the mean and variance of the market index I were selected subjectively, and the Nonlinear Program approximation to the Formal Problem was generated in the following manner: A sample from the distribution governing I was drawn, as were sample values for the ε_i associated with each security i. These values were combined in the formula (1) to produce sample values of the h_i, denoted $r_{11},\ldots,r_{100,1}$. This process was repeated 50 times, resulting in a matrix R having 100 rows, 50 columns, and elements r_{ij}. The Nonlinear Program is thus to

$$\text{Maximize} \quad \sum_{j=1}^{50} \log \left(\sum_{i=1}^{100} x_i r_{ij} \right)$$

with respect to $x_1,\ldots,x_{100}$

subject to $x_i \geq 0$, i=1,...,100,

$$\sum_{i=1}^{100} x_i = 1.$$

The more columns the R matrix has, the more closely it approximates the Formal Problem. Through experimentation, we have determined that 50 columns provide an approximation adequate to support our conclusions.

---

[4] For an informative discussion of the difficulties associated with defining I, α, β, σ^2, and ε in a consistent manner, see Fama [3]. Our procedure is similar to the one he suggests, though he deals with normally distributed returns while ours are assumed lognormal. While many authors, notably Sharpe [10], have worked primarily with normally distributed returns, there is a tendency of late to use the logarithmic model we have chosen. The works of Elton and Gruber [2], and Rosenberg and McKibben [9] are noteworthy in this respect. We found that the lognormal model better fit our data than did the normal model.

Assuming that the investor was not permitted to borrow money or sell securities short, we investigated the characteristics of optimal portfolios under each of six assumptions concerning the market index I in the coming investment period. For each of two assumed values of the standard deviation σ_I of the subjective lognormal distribution governing e^I, the three values .96, 1.00, and 1.04 for the mean μ_I were assumed in succession. As a three-month investment period was envisioned, these means correspond (approximately) to annual market changes of -16%, 0%, and 16%. These values were selected because they were characteristic of quite different market experiences, yet consistent with market behavior in recent years. The two standard deviations investigated were .0907 and .0453, the former being the sample residual standard deviation from the regression against time of the average holding period returns of the 381 securities in the 36-quarter data base.

Subsequently, we permitted the investor to augment his investment capital by borrowing money. To make this possibility attractive, however, it is necessary to alter the Formal Problem, as we do in Section IV.

Under each of the experimental conditions cited above, we determined how many securities comprise an optimal portfolio and whether the particular securities in that portfolio would have been selected for inclusion by any of several portfolio-building heuristics. These heuristic portfolio-building rules are described below.

Portfolio-Building Rules. Since few investors have at their disposal the sophisticated type of nonlinear programming code required to find the optimal geometric mean portfolio, we think it useful to investigate the performance characteristics of several heuristic portfolio-building rules. All but the last of the rules we examine follow the same principle: rank each security on the basis of some criterion and then allocate equal dollar amounts to several of the top-ranked securities. The last portfolio-building rule is a random-selection rule used as a benchmark for the previous rules. It stipulates that several securities be selected at random and equal dollar amounts be invested in each. The four security-ranking criteria chosen for this experiment are described below. The reader should note that the forms of some criteria depend on whether or not borrowing is permitted.

The G criterion: The geometric mean for each security is defined by the formula

$$G = e^{E(\log h_i)} = e^{[\alpha_i + \beta_i E(I)]}$$

where E is the expectation operator and e is Napier's constant. When borrowing is permitted, securities are ranked by G*, a number calculated by finding the optimal leverage to associate with each security.[5]

R/V criterion: The reward to variability ratio was first used by Sharpe [11] to evaluate the performance of mutual fund managers. We use the ratio here as a criterion for ranking individual securities. When no borrowing is permitted, the reward to variability ratio is given by

$$\frac{R}{V}_i = \frac{E(e^{\alpha_i + \beta_i I + \varepsilon_i})}{[VAR(e^{\alpha_i + \beta_i I + \varepsilon_i})]^{1/2}}$$

for security i, where E is the expectation operator and VAR is the variance.

When borrowing is permitted this ratio becomes

$$\frac{R}{V}_i = \frac{E(e^{\alpha_i + \beta_i I + \varepsilon_i}) - r}{[VAR(e^{\alpha_i + \beta_i I + \varepsilon_i})]^{1/2}}$$

for security i, where r is the borrowing rate. A ranking rule employing one or the other of these criteria is called the R/V rule.

The R/NV Criterion: The pure risk yield for each security is obtained by excluding the diversifiable risk component, ε_i, from the numerator and denominator of the reward to variability ratio. It is thus measured by

$$\frac{R}{NV}_i = \frac{E(e^{\alpha_i + \beta_i I})}{[VAR(e^{\alpha_i + \beta_i I})]^{1/2}}$$

for security i in the case where borrowing is not permitted, and by

$$\frac{R}{NV}_i = \frac{E(e^{\alpha_i + \beta_i I}) - r}{[VAR(e^{\alpha_i + \beta_i I})]^{1/2}}$$

when borrowing is permitted. The pure risk yield plays an important role in the portfolio-building rules used by Latane and Tuttle [8]. A ranking rule employing one or the other of these criteria is called the R/NV Rule.

---

[5] More precisely, G* is given by the following:

$$G^* = \underset{\lambda \geq 0}{\text{Max}} \; E\{\log[\lambda e^{\alpha_i} e^{\beta_i I} e^{\varepsilon_i} + (1 - \lambda) h_{101}]\}$$

where h_{101} is the principle-plus-interest due at the end of the investment period per dollar borrowed.

The Kuhn-Tucker Multiplier: With each solution to a Nonlinear Program is associated a collection of constants (called KT multipliers), one for each security in the pool of 100. Each multiplier indicates the impact that inclusion in the portfolio of more of its associated security would have on the geometric mean of that portfolio. Hence, the multiplier is a measure of the desirability of that security, in the context of the others which are available. Assuming that this context is likely to be fairly stable from one investment situation to the next, we sought to predict each security's multiplier as a simple linear function of its α, β, and σ^2 values. The results are remarkably good.

Shown in Table 1 are averages of the coefficients of the regression of α, β, and σ^2 on the KT-multipliers. To obtain the numbers in the compartment corresponding to $\sigma_I = .0907$ and $\mu_I = 1.04$, the regression of KT multipliers on α, β, and σ^2 for each of five optimal portfolios was computed. These portfolios were each built from a pool of one hundred securities drawn independently from the trivariate normal distribution and used only for that one portfolio; hence these five pools were independent of each other and of the pool previously mentioned. The averages of these five sets of regression coefficients, t-statistics and r^2 values are presented in the $\sigma_I = .0907$, $\mu_I = 1.04$ compartment of Table 1. In addition, the standard deviations (in parentheses) of the coefficients suggest that within a set of 100 securities drawn from the trivariate normal distribution, it is possible to predict with fairly good accuracy the KT multiplier associated with that security in a solution to the Formal Problem.

Having in hand a method for predicting Kuhn-Tucker multipliers, we define the KT-rule to be that in which all of the securities are ranked in accordance with their predicted multiplier values, and the top several selected for the portfolio, with equal dollar amounts invested in each.

III. Experimental Results: No Borrowing Permitted

For each of six different assumptions concerning the values of the parameters μ_I, σ_I governing e^I, the optimal solution to the Nonlinear Program was obtained. Each such solution is a recommendation as to the particular securities that should appear in the optimal portfolio, and the proportion of the budget each such security should absorb. This entire process was replicated five times, each time using a different approximation to the Formal Problem, generated by sampling different values of the distributions governing I and the ε_i. The approximations were chosen to be of equal validity, so no one should

be accorded more or less credibility than another.

The results of these experiments are summarized in Table 2. Observe that both for the assumption of large (σ_I = .0907) and small (σ_I = .0453) uncertainty about the performance of the market indicator I, data are presented for a rising market (μ_I = 1.04), a neutral market (μ_I = 1.00), and a falling market (μ_I = .96). These parameter values are intended to reflect possible investor expectations about I at the end of the coming three-month period. The entry in brackets at the upper right of Table 2 is interpreted as follows:

> For the first Nonlinear Program for which σ_I = .0907 and μ_I = 1.04, it is optimal to invest .03 of the investment capital in Security #4, .04 of it in Security #24, and so forth. The geometric mean return gained thereby is 6.274 percent.

The other entries in Table 2 have analogous interpretations.

It is strikingly apparent from Table 2 that an investor adhering to the geometric mean criterion should diversify or not diversify, depending on whether he thinks the market will rise or fall. It is apparent that if the investor believes the market will fall, he should invest in just one security (assuming that he must invest), while in an even market, it appears best to invest in two. For a market expected to rise, the appropriate number of securities appears to be in the range of 4 to 7.[6] This latter variation is due to the differing approximations of each replication to the Formal Problem.

Table 2 also contains a summary of the security characteristics of the 30 optimal portfolios. Within each portfolio, the (α, β, σ) values for each security have been multiplied by the proportion of the capital invested in that security, yielding a ($\bar{\alpha}$, $\bar{\beta}$, $\bar{\sigma}$) representation for each portfolio. The five portfolio representations were then averaged to obtain ($\bar{\bar{\alpha}}$, $\bar{\bar{\beta}}$, $\bar{\bar{\sigma}}$). A standard deviation (in parentheses) is computed over the five portfolio samples.

It appears from Table 2 that if a rising market is anticipated, then it is desirable to invest in securities for which β_i and σ_i are large, and for which α_i is small. If the market is expected to decline, then stocks with high α_i and low β_i and σ_i values should be sought. Examination of the individual (α, β, σ) triples (as available from the authors) appearing in the various portfolios sustains the suggestion.

[6] These numbers of securities are obtained under the assumption that the investor has 100 securities from which to choose. If he has 1000 such securities, the optimal number to hold may tend to increase somewhat. Similarly, if the market indicator I is expected to increase (decrease) more (less) than 4 percent, a somewhat larger (smaller) number of securities should be held.

	[45 / 1.00] 2.666%	[41 45 / .27 .73] 2.859%	[4 24 43 59 67 70 / .07 .05 .02 .30 .06 .50] 6.752%
	$\bar{\alpha} = .026$ (.000)	$\bar{\alpha} = .028$ (.000)	$\bar{\alpha} = .001$ (.001)
	$\bar{\beta} = .042$ (.000)	$\bar{\beta} = .178$ (.009)	$\bar{\beta} = 1.502$ (.032)
	$\bar{\sigma} = .024$ (.000)	$\bar{\sigma} = .036$ (.001)	$\bar{\sigma} = .132$ (.003)

The interplay of effects resulting in the above conclusion may be as follows. First, the correlation matrix (2) for the (α, β, σ^2) values occurring in market securities indicates that large α values are associated with small β and σ^2 values, and conversely. That is, stocks with small β values tend to show both little systematic and nonsystematic risk, while stocks with large values tend to have small (perhaps negative) α and large σ^2 values. If a declining market is anticipated, the investor seeks stocks for which α is large and can generally find one for which β and σ^2 are small, perhaps a utility with a high current dividend income. If the market is expected to rise, he seeks securities with large β values, but is generally then forced to consider stocks with high σ^2 values. To counter this high degree of uncertainty, he diversifies among several such securities, and thereby reduces his vulnerability to nonsystematic risk in holding period returns.

The results of our experiments using the portfolio-building rules are summarized in Table 3. For each building rule, we assumed that the investor chooses the number of securities he wishes to hold equal to the number found in the optimal portfolio. The investor decides which market behavior best represents his beliefs, and this in turn determines the number of securities he should hold. The particular securities he chooses depend upon which criterion he employs.

Several features of the data in Table 3 are especially interesting. First, in a falling market, all of the portfolio-building rules work optimally, save the random rule. In an even market, the G-Rule triumphed in the market with $\sigma_I = .0907$, while it was tied by the KT-Rule in the case where $\sigma_I = .0453$. In the rising market, the KT-Rule and the G-Rule again vied for superiority, with the KT-Rule showing a slight advantage. It is a curious circumstance that the R/V and R/NV Rules were, in this case, inferior to the Random Rule. This situation changes considerably when borrowing is permitted, as we describe next.

IV. The Case in Which Borrowing Is Permitted

The Formal Problem. The possibility of borrowing can be incorporated in the Formal Problem by introducing a new security, the one-hundred-first, whose coefficient x_{101} is required to be nonpositive. The "holding period return" h_{101} is the principle-plus-interest due at the period's end per dollar borrowed. Note that because the probability density function governing each h_i is positive for positive values of h_i, there is a nonzero probability that the terminal value $\sum_{i=1}^{100} x_i h_i$ of the portfolio will be less than the amount $-x_{101}h_{101}$

Table 3. Quarterly Geometric Rates of Return for Selected Portfolio Construction Rules Under Various Market Index Assumptions; Averages (Standard Deviations) over Five Replications

Page 627 of 739

due in repayment of the loan (unless $x_{101} = 0$; that is, unless no money was borrowed). In this circumstance we may define the investor's end-of-period wealth to be zero, a condition which is associated with infinitely negative utility. Inviting such a bankruptcy condition with positive probability renders the Formal Problem objective function negatively infinite, a situation inferior to any in which $x_{101} = 0$. Hence, borrowing is never an optimal policy for the Formal Problem. This is a rather surprising result in view of the common practice of borrowing money to invest, and it suggests that there may be some inadequacies in the Formal Problem.

One modification of the Formal Problem which is consistent with an optimal multiperiod program for portfolio management, and in which borrowing is a viable option is obtained by introducing a new security, the zeroth, in which a fixed proportion x_0 of wealth must be invested. This restriction might reflect the desires of the investor to hold the proportion x_0 of his wealth in some form such as art or real estate, and to liquidate it only in an extreme situation. This Modified Formal Problem is stated as follows:

$$\text{Maximize} \quad E\{\log \left(\sum_{i=0}^{101} x_i h_i \right)\}$$

$$\text{with respect to} \quad x_0, \ldots, x_{101}$$

$$\text{subject to}$$

$$\sum_{i=0}^{101} x_i = 1,$$

$$x_o = \tau, \text{ a known constant,}$$

$$x_i \geq 0, \quad 1 \leq i \leq 100,$$

$$-b \leq x_{101} \leq 0.$$

The constant b is a limit on the proportion of wealth that can be borrowed; it is analogous to a margin requirement. As one avoids borrowing in the Formal Problem, so too does one avoid over-borrowing in the Modified Formal Problem. It is easily shown that one should never permit $x_0 h_0 + x_{101} h_{101}$ to go negative, so that an immediate limit on borrowing is $0 \geq x_{101} \geq -(\tau h_0)/h_{101}$.

In obtaining numerically the characteristics of solutions to the Modified Formal Problem, we approximated the latter with stochastically drawn Nonlinear Programs, as was done with the Formal Problem. The parameter values we used were $h_0 = 1$, and $x_0 = \tau = .506$. These parameters imply that $b = .494$, which is equivalent to limiting the borrowing capacity by a 50 percent margin requirement.

In Table 4 are shown solutions to five Nonlinear Programming problems approximating the Modified Formal Problem in which $b = 0$; that is, in which borrowing is not permitted. In comparing this to Table 2, we observe that the effect of requiring $x_0 = .506$ is to decrease the geometric mean return on total wealth and to decrease the number of securities bought. However, the arithmetic mean return on the securities portion of the portfolio has increased, which is consistent with decreasing risk aversion of the investor. Comparison of Tables 2 and 4 also shows that a further effect is to cause the investor to choose stocks with higher β and σ values.

Permitting borrowing to the limit $b = .494$ at an interest rate of 2.5 percent per quarter led to the exact same portfolios found in the analysis of the original Formal Problem and exhibited in Table 2, though the geometric mean returns were somewhat lower because full advantage was taken of the option to borrow, and so some capital was expended on interest payments.

In Table 5 are shown the characteristics of portfolios built using various rules, in case borrowing is permitted and $\mu = 1.04$, $\sigma_I = .0907$. We deem this the most interesting market situation, in light of the relatively drab policies suggested in Table 2 for other circumstances. If for each rule one selects a portfolio containing the same number of securities as found in the optimal portfolio, then the KT- and G-Rules outperform the other rules and yield portfolios which are nearly optimal. It is heartening to note also that the Random Rule is least attractive under these circumstances, in contrast to the situation depicted in Table 3.

V. Summary and Conclusions

We began this paper by posing four questions about the characteristics of optimal geometric mean portfolios. Tentative answers to these questions were obtained from an examination of the solutions to a relatively large number of geometric mean portfolio problems generated from a Monte Carlo simulation of ex-ante security return data. The results of this examination can be summarized as follows. First, the number of risky securities contained in an optimal geometric mean portfolio depends on one's expectations concerning future market

Table 4. Optimal Portfolios for the Case $x_0 = .506$, $b = 0$, Five Replications; Averages (Standard Deviations) over Five Replications of the Portfolio Characteristics

Assumptions:

Borrowing Limit b = .494

Withheld Capital x_0 = .506

Interest Rate = 2.5% per quarter

conditions and on the conditions under which borrowing is permitted. If all capital must be invested, the investor who believes the market will fall should invest in just one security, he who believes the market will remain unchanged should diversify among two securities, while he who believes the market will rise should diversify among four to seven securities.[7] In the event that some capital must be withheld from investment, the investor who believes the market will rise and who can borrow on reasonable terms will again diversify among four to seven securities, choosing the same securities in the same relative proportions as in the preceding situation. Should the investor be permitted neither to borrow nor to invest all his capital, his best portfolio consists of two to four securities, assuming he expects the market to rise.

Second, the individual characteristics of securities contained in optimal geometric mean portfolios also depend on one's assumptions about market conditions and the availability of borrowing. It appears that if a rising market is anticipated, then it is desirable to invest in securities for which β_i and σ_i are large, and for which α_i is small. If the market is expected to decline, then stocks with high α_i and low β_i and σ_i should be sought. The effect of not permitting an investor to borrow and requiring him to withhold capital from investment is to make him seek stocks with especially large values of β and σ^2 in the event he expects the market to rise.

Third, the returns obtained from optimal geometric mean portfolios can sometimes be approximated with the use of heuristic portfolio-building rules. Among the rules which we investigated, the KT- and G-Rules offer the most nearly optimal returns in all market conditions.

Principles for Lifetime Portfolio Selection: Lessons from Portfolio Theory*

James H. Vander Weide
Duke University, The Fuqua School of Business

Abstract

Portfolio theory is concerned with developing general principles and practical models for making sound lifetime portfolio decisions. Much of the current research on portfolio theory emanates from the path-breaking mean-variance portfolio model of Nobel Laureate Harry Markowitz. Although the mean-variance model continues to be the most widely used portfolio model in financial practice, economists have devoted considerable effort to research on two additional models of portfolio behavior, the geometric mean model and the lifetime consumption-investment model. These models are also useful to investors because they offer significant additional insights into optimal portfolio behavior. The purpose of this paper is to review the major findings of the research literature on the mean-variance model, the geometric mean model, and the lifetime consumption-investment model, and, on the basis of this review, to develop a set of practical guidelines for making lifetime portfolio decisions.

* I appreciate the helpful comments of John Guerard, David Peterson, David Vander Weide, and two anonymous referees.

I. Introduction

1. An individual's savings and investment choices at various stages of life are among the most important decisions he or she can make. A person entering the workforce in 2008 can expect to work for approximately 40 to 45 years and to live in retirement for an additional 20 to 25 years. During his working life, an individual must accumulate sufficient assets not only to live comfortably in both good and bad economic times, but also to live comfortably in retirement. To achieve the goal of maximizing economic welfare over his expected lifetime, an individual consumer/investor should have a sound understanding of the basic economic principles of lifetime portfolio selection.

2. The lifetime consumption/investment decision problem is complex. Suppose an individual consumer/investor divides her expected remaining lifetime into N equal periods. At the beginning of period 1, she must allocate her wealth W_0 to consumption C_0 and investment W_0-C_0. Her wealth at the beginning of the next period, W_1, will depend on both the amount she chooses to invest at the beginning of period 1 and the return she earns on her investment. The consumer/investor recognizes that she will continue to make consumption/investment decisions at the beginning of each period of her life. Her goal is to maximize her expected utility from lifetime consumption. Since expected utility from lifetime consumption depends on consumption/investment decisions in every period of her life, and the opportunities in later periods depend on the results of decisions in earlier periods, the individual consumer/investor must potentially solve a complex N period optimization problem simply to make the correct consumption/investment decision at the beginning of period 1.

3. Portfolio theory is concerned with developing general principles and practical models for making sound lifetime portfolio decisions. Much of the current research on portfolio theory emanates from the path-breaking mean-variance portfolio model of Nobel Laureate Harry

Markowitz. Markowitz (1952, 1959) recommends that in making investment decisions, investors should explicitly recognize investment risk as measured by variance of return, as well as expected return. He describes how the variance of return on a portfolio of securities depends on the amount invested in each security, the variance of return on each security, and the correlation between the returns on each pair of securities. He also suggests that investors limit their choices to an efficient set of portfolios that provide the highest mean return for any level of variance and the lowest variance of return for any level of mean. By providing an intuitively appealing measure of portfolio risk and a framework for analyzing the basic risk/return tradeoff of portfolio decisions, Markowitz revolutionized both the theory and practice of portfolio management. For that reason, Markowitz is properly called the father of Modern Portfolio Theory.[1]

4. The beauty of the Markowitz mean-variance model lies in its blend of elegance and simplicity. Markowitz achieves elegance by providing investors a sophisticated tool for: (i) understanding how portfolio mix decisions affect portfolio risk; and (ii) determining those portfolios that provide an efficient combination of risk and return. He achieves simplicity by focusing solely on the economic trade-off between portfolio risk and return in a single-period world.[2]

5. Although the mean-variance model continues to be the most widely used portfolio model in financial practice, economists have devoted considerable effort to research on two additional models of portfolio behavior, the geometric mean model and the lifetime consumption-investment model. These models offer significant additional insights into optimal

[1] This paper is dedicated to Dr. Markowitz in celebration of his 80th birthday.
[2] Markowitz discusses many of the dynamic economic forces that affect lifetime consumption and investment decisions in the later chapters of Markowitz (1959). However, the economic forces described in this discussion are not incorporated directly in his single-period mean-variance model.

portfolio behavior. The purpose of this paper is to review the major findings of the research literature on the mean-variance model, the geometric mean model, and the lifetime consumption-investment model, and, on the basis of this review, to develop a set of practical guidelines for making lifetime portfolio decisions.

II. The Markowitz Mean-variance Model

6. Investors make portfolio decisions by selecting the securities to include in the portfolio and the amount to invest in each security. In making risky portfolio choices, the Markowitz mean-variance approach assumes that investors: (1) consider only the mean and variance of the probability distribution of portfolio and security returns; (2) for a given level of mean return, prefer a portfolio with a lower variance of return; and (3) for a given level of variance of return, prefer a portfolio with a higher mean return.

7. As Markowitz demonstrates, the above assumptions suggest that an investor's portfolio decision problem can be solved in three steps. First, an investor can estimate the mean and variance of return on each security and the correlation of returns on each pair of securities. Second, an investor can calculate the mean and variance of return on each feasible portfolio and determine an "efficient frontier" of portfolios that offer the lowest variance of return for any level of mean return and the highest mean return for any level of variance of return. Third, an investor can choose a portfolio on the efficient frontier. This paper will focus primarily on steps two and three.

A. Estimating the Mean and Variance of Portfolio Returns

8. Assume that there are N securities and that an investor allocates the proportion X_i of his wealth to security i. Let R_i denote the return on security i and R_p the return on the portfolio of N securities. Then:

$$R_p = R_1 X_1 + R_2 X_2 + \cdots + R_n X_n, \quad \textbf{(1)}$$

where R_p and $R_1 \ldots R_n$ are random variables.

9. According to Equation (1), the portfolio return, R_p, is a weighted average of the returns on the securities in the portfolio. Formulas for calculating the mean and variance of a weighted sum of random variables are presented in most introductory probability texts. Using these formulas, the mean of the portfolio return, E_p, is given by:

$$E_p = E_1 X_1 + E_2 X_2 + \cdots + E_n X_n, \quad \textbf{(2)}$$

where $E_1, \ldots, E_n$, are the mean, or expected, returns on the individual securities; and the variance of the portfolio return is given by:

$$V_p = \sum_i V_i X_i^2 + \sum_i \sum_{j>i} 2 C_{ij} X_i X_j, \quad \textbf{(3)}$$

where V_i is the variance of return on security i, and C_{ij} is the covariance of returns on security *i* and security *j*.

10. In the Markowitz mean-variance model, investment risk is measured by either the variance of the portfolio return or its equivalent, the standard deviation of portfolio return.[3] The formula for portfolio variance, Equation (3), can be used to provide insight on how investors can reduce the risk of their portfolio investment. Recall that the covariance of returns on security i and security j can be written as the product of the standard deviation of return on security i, SD_i, the standard deviation of the return on security j, SD_j, and the correlation of returns on securities i and j, ρ_{ij}:

$$C_{ij} = SD_i \times SD_j \times \rho_{ij}. \quad \textbf{(4)}$$

[3] Variance and standard deviation of return are considered to be equivalent measures of risk because the standard deviation is the positive square root of the variance, and the positive square root is an order-preserving transformation. Thus, portfolios that minimize the variance of return for any level of mean return will also minimize the standard deviation of return for any level of mean return.

To simplify the analysis, assume that: (i) the variances on all securities are equal to the average security variance, $\bar{V}$; (ii) the correlation of returns on all securities i and j are equal to the average correlation of return, $\bar{\rho}$, on securities; and (iii) the investor allocates 1/N of his wealth to all securities.

11. Under these assumptions, the variance of return on the portfolio, V_p, can be written as:

$$V_p = \bar{V}(\frac{1}{N}) + \frac{N(N-1)}{N^2}\bar{V}\bar{\rho}. \quad \textbf{(5)}$$

The effect of variations in $\bar{V}$, $\bar{\rho}$, and N on portfolio variance, V_p, can be determined by calculating the partial derivative of V_p, with respect to each of these variables:

$$\begin{aligned}
&\frac{\partial V_p}{\partial \bar{V}} = \frac{1}{N} + \frac{N(N-1)}{N^2}\bar{\rho} > 0 \quad \text{if} \quad \bar{\rho} \geq 0 \\
&\frac{\partial V_p}{\partial \bar{\rho}} = \frac{N(N-1)}{N^2}\bar{V} > 0 \\
&\frac{\partial V_p}{\partial N} = -\bar{V}(\frac{1}{N^2}) + \bar{V}\bar{\rho}(\frac{1}{N^2}) = \bar{V}(\bar{\rho}-1)(\frac{1}{N^2}) \leq 0.
\end{aligned} \quad \textbf{(6)}$$

These equations indicate that the portfolio variance of return can be reduced in three ways: (i) increasing the number of securities in the portfolio; (ii) choosing securities having returns that are less correlated with returns on other securities; and (iii) if $\bar{\rho}$ is greater than or equal to zero, choosing securities with low variance or standard deviation of returns.

12. The formulas for portfolio mean and variance, given by Equation (2) and Equation (3), require estimates of the mean, E_i, and variance, V_i, of return on each security, as well as the covariance, C_{ij}, of returns on each pair of securities. If there are N securities under

consideration, Equation (2) and Equation (3) require N mean estimates, N variance estimates, and N (N – 1)/2 distinct covariance estimates, for a total of 2N + N x (N-1)/2 estimates. To illustrate, assume that an analyst is considering 200 securities for possible inclusion in a portfolio. Then the analyst must estimate 200 mean values, 200 variance values, and 19,900 covariance values to implement the Markowitz mean-variance model. Without simplification, it is unlikely that the analyst could estimate these inputs cost effectively.

13. One way to reduce the large number of estimates required to implement the Markowitz mean-variance model is to apply the model to asset classes rather than to individual securities. For example, if the universe of securities is divided into large U.S. stocks, small U.S. stocks, global stocks, emerging market stocks, corporate bonds, long-term U.S. government bonds and Treasury bills, the number of input estimates would be reduced from 20,300 to 35. Given the importance of the asset mix decision and the significant reductions in required estimates obtainable by considering asset categories rather than individual securities, it is not surprising that the Markowitz model is frequently applied to asset categories rather than to individual securities.

14. Another way to reduce the input requirements of the Markowitz mean-variance model is to make one or more simplifying assumptions about the covariance structure of security returns. For example, if one assumes that: (i) the return on an individual security i is related to the return on a market index via the equation:

$$R_i = \alpha_i + \beta_i R_m + e_i \quad \text{for } i = 1,2,\cdots,N \tag{7}$$

where R_i is the return on security i, R_m is the return on the market index, and e_i is a random error term; (ii) $E[e_i(R_m - \overline{R_m})] = 0$; and (iii) $E(e_i \times e_j) = 0$; then the means, variances, and covariances of securities' returns are given by:

$$E_i = \alpha_i + \beta_i E_m \quad \textbf{(8)}$$

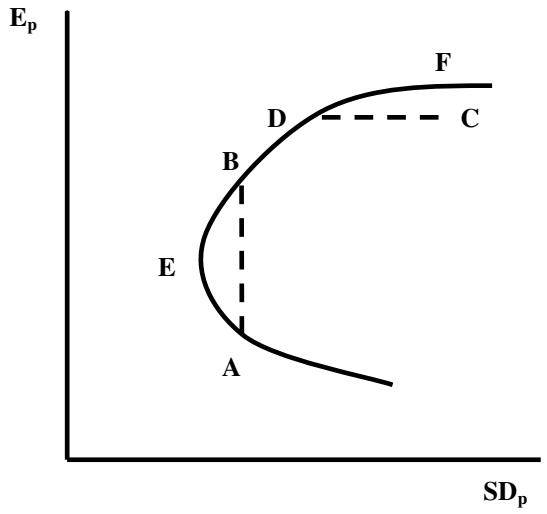
$$V_i = \beta_i^2 V_m + V_{ei}, \quad \textbf{(9)}$$

$$C_{ij} = \beta_i \beta_j V_m. \quad \textbf{(10)}$$

15. Substituting Equations (8), (9), and (10) into Equations (2) and (3), we obtain the following equations for the mean and variance of return on a portfolio of securities:

$$E_p = \sum_i X_i (\alpha_i + \beta_i E_m) \quad \textbf{(11)}$$

$$V_p = \sum_i X_i{}^2 \beta_i^2 V_m + \sum_i \sum_{j \neq i} X_i X_j \beta_i \beta_j V_m + \sum_i X_i{}^2 V_{ei}. \quad \textbf{(12)}$$



To estimate the mean and variance of return on any portfolio then, we need only to estimate the α_i, β_i, and V_{ei} inputs for each security and the expected return, E_m, and variance of return, V_m, on the market index. Thus, the total number of required estimates has been reduced from $2N + [N \times (N-1)]/2$ to 3N + 2. If the analyst is considering 200 securities for possible inclusion in a portfolio, the number of required estimates is reduced from 20,300 to 602.

B. The Feasible Set of Portfolios and the Efficient Frontier

16. The feasible set of portfolios is the set of all security allocations (X_1, … X_N) that satisfy the individual's portfolio constraints. An obvious portfolio constraint is that the sum of the proportion of wealth invested in all securities must equal 1. Other typical constraints are that the proportion invested in each security must be non-negative (that is, short selling is not allowed) and the investor will not invest more than a certain percentage of wealth in any one security.

17. The Markowitz mean-variance portfolio model allows an investor to translate all feasible portfolio proportions (X_1, … X_N) into feasible combinations of: (i) expected return and variance of return; or (ii) expected return and standard deviation of return. Figure I shows one such feasible set of E_p, SD_p, combinations. Consider portfolio A shown in Figure I. Rational Markowitz mean-variance investors would not choose to invest in portfolio A because they could achieve a higher expected return by investing in portfolio B without increasing the portfolio standard deviation. Similarly, rational investors would not invest in portfolio C because they could achieve a lower portfolio standard deviation by investing in portfolio D without sacrificing mean return. The efficient set of portfolios consists of all portfolios with the highest mean return for any given level of standard deviation of return and the lowest standard deviation of return for any given level of mean return. The curved line EBDF is the efficient frontier for the feasible set of risky portfolios shown in Figure I.

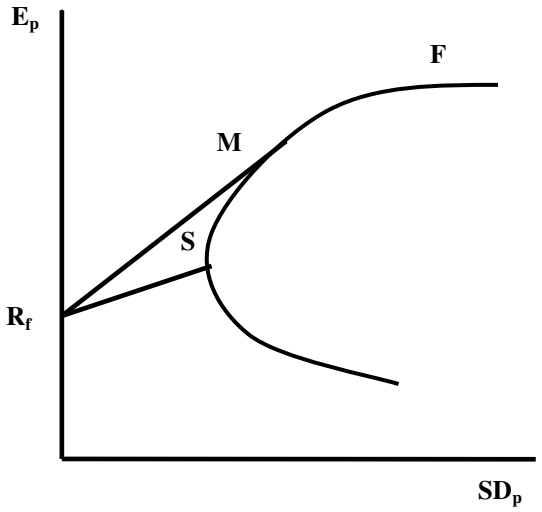


Figure I

C. The Effect of a Risk-free Security on the Shape of the Efficient Frontier

18. When all securities are risky, the efficient frontier typically has a shape similar to that shown in Figure I. Suppose now there exists a security with a risk-free rate of return, R_f. Since the risk-free security has zero variance, its mean-standard deviation combination lies on the vertical axis in mean-standard deviation space (see Figure II). In addition, the risk-free security must lie on the efficient frontier because there are no other securities with the same mean return and a lower standard deviation of return.

Figure II

19. To see how the shapes of the feasible set of securities and the efficient frontier change as a result of the presence of a risk-free security, consider a new portfolio consisting of the fraction X invested in a portfolio S of risky securities and a fraction (1-X) invested in the risk-free security. Because the return on the risk-free security has zero variance and is uncorrelated with the return on portfolio S, both the mean and standard deviation of return on the new portfolio are linearly related to the mean and standard deviation of return on portfolio S.[4]

[4] Specifically, $E_p = X \cdot E_s + (1 - X) R_f$ and $SD_p = X \cdot SD_s$.

Thus, the new portfolio lies somewhere on the straight line connecting R_f and S in Figure II, with its exact location depending on the fraction of wealth X invested in portfolio S.

20. Since the risky portfolio S in the above example is selected arbitrarily, the revised set of feasible portfolios consists of E_p, SD_p combinations lying on any line connecting R_f with a point such as S in the feasible set of risky portfolios. The slope of such a line is $(E_s - R_f)/SD_s$. Consider now the line connecting R_f with portfolio M in Figure II. The points on this line represent feasible portfolios with the fraction X invested in the risky portfolio M and the fraction (1-X) invested in the risk-free security. Since the slope $(E_M - R_f)/SD_M$ is greater than the slope $(E_s - R_f)/SD_s$ for any risky portfolio S, for any feasible portfolio not on the line connecting R_f and risky portfolio M, there exists a portfolio on the line connecting R_f and risky portfolio M with a higher mean return and the same standard deviation of return or the same mean return and a lower standard deviation of return. Thus, the points on the line connecting R_f and M are not only feasible but also efficient. Evidently, the new efficient frontier consists of the union of all points on the line connecting R_f and M and all points on the efficient frontier of risky securities between M and F.[5]

D. Identifying the Efficient Frontier

21. As noted above, the efficient set of portfolios consists of all portfolios with the highest mean return for a given level of variance or standard deviation and the lowest variance (standard deviation) for a given level of mean. Once the E_i, V_i, and C_{ij} inputs have been estimated, the analyst can calculate the mean-variance efficient frontier by solving the following optimization problem for all non-negative values of the parameter λ:

[5] This conclusion strictly applies only when the investor cannot finance risky investments with borrowing. If the investor can borrow as well as lend at the risk-free rate, the efficient frontier will consist of the entire straight line emanating from R_f and extending through the tangency point M on the efficient frontier of risky securities.

$$\begin{aligned} &\text{Minimize } V_p - \lambda E_p \\ &\text{with respect to } X_1, X_2 \cdots, X_N \\ &\text{subject to } \sum_i X_i = 1 \\ &X_i \geq 0; i = 1, \cdots, N. \end{aligned} \tag{13}$$

22. The above problem is called the standard mean-variance portfolio selection problem. Non-standard forms of the mean-variance portfolio selection problem include cases where: (i) additional linear constraints apply, and (ii) the amounts invested in one or more securities may be negative. Markowitz (1956, 1959, and 2000) describes efficient algorithms for solving both standard and non-standard versions of the mean-variance portfolio selection problem. These algorithms are used extensively in practical mean-variance portfolio analysis.

23. Elton, Gruber, and Padberg (1976, 1978) demonstrate that an alternative simple procedure can be used to select mean-variance efficient portfolios when the single-index model, Equation (7), is accepted as the best method of forecasting mean-variance portfolio inputs. Their simple procedure requires that securities be ranked based on the ratio of their expected excess return to their beta:

$$(E_i - R_f) \Big/ \beta_i \tag{14}$$

where E_i is the expected return on security i, R_f is the return on the risk-free security, and β_i is the sensitivity of the return on security i to changes in the market index as measured by Equation (7). Elton, Gruber, and Padberg prove that all risky securities with an excess return to β ratio above a specific cut-off, C^*, should be included in a mean-variance efficient portfolio; and all risky securities with an excess return to β ratio below this cut-off value should be excluded. Formulas for C* for both the case where short sales are not permitted and the case where short sales are permitted are given in Elton, Gruber, and Padberg's papers.

E. Choosing the "Best" Portfolio on the Efficient Frontier

24. In the Markowitz mean-variance model, an investor should always choose a portfolio on the mean-variance efficient frontier. However, the investor's choice of the best portfolio on the efficient frontier depends on his or her attitude toward risk. Risk-averse investors will likely choose efficient portfolios near the minimum risk portfolio, E, on the efficient frontier in Figure I (or R_f on the efficient frontier in Figure II), while risk-tolerant investors will likely choose portfolios near the maximum mean portfolio, F.

25. But how does the investor actually make the choice of the "best" portfolio on the efficient frontier? It appears that there are two alternatives: direct choice, and investor utility functions. Direct choice involves a direct comparison of the mean and standard deviation of various portfolios on the efficient frontier. In the direct choice approach, the investor is simply presented with information on the means and standard deviations of various portfolios on the efficient frontier and asked to choose a preferred combination of mean and variance.

26. In contrast, investor utility functions involve an attempt to capture the investor's aversion to risk in the form of an investor-specific utility function:

$$U = E_p - kV_p, \tag{15}$$

where k is a parameter indicating the investor's aversion to risk, as measured by variance of return. In this approach, a portfolio advisor would estimate an investor's risk aversion parameter, k, from the investor's responses to a series of questions regarding the investor's attitude toward risk. Investors with high risk aversion would be assigned high values of k, while investors with low risk aversion would be assigned low values of k. The advisor would then calculate the utility, U, of each portfolio on the efficient frontier and recommend the portfolio with the highest utility.

27. In the tradition of Bernoulli (1738) and von Neuman and Morgenstern (1946), economists generally assume that investors wish to maximize their expected utility of wealth, an assumption that has allowed economists to derive a rich set of conclusions about investment behavior. However, practitioners have found that for most investors, utility functions are an impractical device for selecting portfolios. In their experience, they find that investors do not understand the concept of utility and are generally unable to provide the information required to determine their utility function analytically. While this conclusion probably explains the minimal use of utility functions in practical portfolio analysis, it does not rule out using utility functions to obtain practical insights into optimal investment policies for typical investors. Indeed, we demonstrate below how utility analysis has produced many useful guidelines for lifetime consumption-investment decision making.

F. Comments on the Mean-variance Model

28. The Markowitz mean-variance portfolio model has undoubtedly been one of the most influential models in the history of finance. Since its introduction in 1952, the mean-variance model has provided an intellectual foundation for much later research in finance. Because of its rich practical insights, the Markowitz model also continues to strongly influence practical financial management. Nonetheless, the mean-variance approach to portfolio selection is sometimes criticized because it implicitly assumes that information on a portfolio's mean return and variance of return is sufficient for investors to make rational portfolio decisions. Tobin (1958) notes that information on a portfolio's mean return and variance of return is only sufficient for rational portfolio decision making if: (i) the investor's utility function is quadratic; or (ii) the probability distribution of security returns is normal. Neither of these assumptions is likely to be strictly true.

29. Economists generally agree that a reasonable utility function should display non-satiety, risk aversion, decreasing absolute risk aversion, and constant relative risk aversion.[6] The problem with a quadratic utility function is that it displays satiety (that is, an investor with this utility function eventually prefers less wealth rather than more); and increasing absolute and relative risk aversion. Mossin (1968) demonstrates that the only utility functions that satisfy all four of the above desirable characteristics of utility functions are the logarithmic function, $\log W$,[7] and the power function, $W^{1-\gamma}$. Thus, the assumption that it is rational for investors to evaluate risky choices based solely on the mean and variance of return cannot be strictly justified on the grounds that investors' utility functions are quadratic.

30. The other way to justify the assumption that investors base their risky choices solely on the mean and variance of returns is that security returns are normally distributed. But this justification is also problematic. The normal distribution is symmetric with a positive probability that returns can take any value on the real line. However, with limited liability, an investor can never lose more than his entire wealth—that is, $(1+r_t)$ must be greater than or equal to zero. In addition, the investor's multi-period return is the product of individual period returns, and the product of normally distributed variables is not normally distributed. Thus the rationality of relying solely on the mean and variance of portfolio returns cannot be strictly justified on the grounds that returns are normally distributed.

31. Markowitz (1959), Levy and Markowitz (1979), and Samuelson (1970), among other prominent economists, recognize that investor utility functions are unlikely to be quadratic and that security return distributions are unlikely to be normally distributed. However, they

[6] The desirable attributes of utility functions are discussed more fully below.
[7] In this paper, we use the notation, log W, to indicate the natural logarithm of W.

defend the validity of the mean-variance approach to portfolio decision making based on the belief that one or more of the following statements is true:

- Within any interval, utility functions are approximately quadratic.
- Probability distributions can often be approximated by their first two moments.
- The mean-variance model, though not strictly rational, is nonetheless useful for investors because it provides information that investors find to be relevant and leads them to make better decisions than they would in the absence of the model.

Indeed, Markowitz and Levy and Markowitz demonstrate that many utility functions are approximately quadratic in any interval; Samuelson demonstrates that probability distributions can under fairly general conditions be approximated by their first two moments; and the prevalence of the mean-variance framework in practical decision making suggests that the mean-variance model is useful to investors.

III. The Geometric Mean Portfolio Model

32. As described above, Markowitz achieves simplicity in the mean-variance model by focusing on the economic trade-off between risk and return in a single-period world. However, many investors make portfolio decisions in a multi-period world where portfolios can be rebalanced periodically. For these investors, Latané (1959) recommends an alternative framework, the geometric mean portfolio model. He argues that the maximum geometric mean strategy will almost surely lead to greater wealth in the long run than any significantly different portfolio strategy, a result that follows from similar conclusions of Kelly (1957) in the context of information theory. Breiman (1960, 1961) states the precise conditions for which this result holds and develops additional properties of the geometric mean strategy. A recent news article

describes how two well-known fund managers, Edward Thorp and Bill Gross, have used the geometric mean portfolio strategy to improve the performance of their funds.[8]

A. The Geometric Mean Strategy and Long-run Wealth Maximization

33. Consider an investor who invests an amount, W_0, at the beginning of period 1 and earns a known rate of return on investment of $R_t = (1+r_t)$ in periods t = 1, …, T. If the investor reinvests all proceeds from his investment in each period, his wealth at the end of period T will be:

$$\begin{aligned} W_T &= W_0(1+r_1)(1+r_2)\cdots(1+r_T) \\ &= W_0\prod_t R_t. \end{aligned} \tag{16}$$

Let G=(1+g) denote the investor's compound average, or geometric mean, return on his investment over the period from 1 to T. Then,

$$\begin{aligned} G &= [(1+r_1)(1+r_2)\cdots(1+r_T)]^{1/T} \\ &= \prod_t R_t^{1/T}. \end{aligned} \tag{17}$$

Since $W_T = W_0G^T$, the investor's terminal wealth, W_T, will be maximized when the geometric mean return on investment, G, is maximized.

34. In practice, the returns $R_t = (1+r_t)$ for t = 1, …, T are uncertain at the time the investor makes the initial investment decision. Assume that the return on investment is independently and identically distributed, and that there are J possible outcomes for R. Let P_j denote the probability of obtaining the j^{th} return outcome. Then, the forward-looking geometric mean return on investment in this uncertain case is defined as:

[8] "Old Pros Size Up the Game, Thorp and Pimco's Gross Open Up on Dangers of Over-betting, How to Play the Bond Market," *The Wall Street Journal*, Saturday/Sunday, March 22-23, 2008.

$$G^E = \prod_j R_j^{P_j}. \quad (18)$$

In the geometric mean portfolio model, the investor's objective is to maximize the forward-looking geometric mean return on investment, G^E.

35. When analyzing a variable such as G or G^E that is equal to the product of other variables, it is frequently convenient to analyze the logarithm of the variable rather than the variable itself. From Equation (18), the log of G^E is equal to the expected log return on investment:

$$\begin{aligned} \log G^E &= \sum_j P_j \log R_j \\ &= E \log R. \end{aligned} \quad (19)$$

Because the log function is monotonically increasing throughout its domain, any portfolio that maximizes G^E will also maximize log G^E, and hence E log R. Thus, the geometric mean portfolio strategy is equivalent to a portfolio strategy that seeks to maximize the expected log return on investment, E log R.

36. Since the return on investment is assumed to be independently and identically distributed, the T values for R shown in the definition of G in Equation (17) can be considered to be a random sample of size T from the probability distribution for R. Let G^S denote the geometric mean return calculated from the random sample of size T from the probability distribution for R and log G^S denote the log of the sample geometric mean return. From Equation (17), log G^S is given by:

$$\log G^S = \frac{1}{T} \sum_t \log R_t. \quad (20)$$

According to the weak law of large numbers, the average of the sample values of a random variable will approach the expected value of the random variable as the sample size T approaches infinity. Presuming that the mean and variance of log R are finite, the weak law of large numbers assures that for any positive numbers ε and δ, no matter how small, there exists some positive number τ, perhaps large but nevertheless finite, such that for all T>τ,

$$\text{Prob}\left\{\left|\frac{1}{T}\sum_t \log R_t - E\log R\right| < \varepsilon\right\} \geq 1-\delta. \quad (21)$$

An alternate notation for this condition is

$$\text{plim}\left(\frac{1}{T}\sum_t \log R_t\right) = E\log R, \quad (22)$$

where plim denotes probability limit.

37. Let R^A denote the investor's returns under the maximum geometric mean strategy, and R^B denote the investor's returns under a significantly different strategy.[9] Then, from the above discussion, we know that:

$$\text{plim}\left(\frac{1}{T}\sum_t \log R_t^A\right) = E\log R^A, \quad (23)$$

$$\text{plim}\left(\frac{1}{T}\sum_t \log R_t^B\right) = E\log R^B, \quad (24)$$

and

$$E\log R^A > E\log R^B. \quad (25)$$

Thus,

$$\text{plim}\left(\frac{1}{T}\sum_t \log R_t^A\right) > \text{plim}\left(\frac{1}{T}\sum_t \log R_t^B\right). \quad (26)$$

[9] By "significantly different strategy," we mean a strategy that has a lower expected log return than the maximum geometric mean strategy.

This is turn implies that for T sufficiently large, it is virtually certain that $\left(\frac{1}{T}\right)\sum_t \log R_t^A$ will exceed $\left(\frac{1}{T}\right)\sum_t \log R_t^B$, and do so by an amount very nearly equal to (E log R^A – E log R^B) > 0. That is, in the long run, the investor will almost surely have greater wealth by using the geometric mean strategy than by using any significantly different strategy.

B. The Relationship between the Geometric Mean Strategy and the Log Utility Function

38. As shown above, the geometric mean portfolio strategy: (i) almost surely produces greater wealth in the long run than any significantly different strategy; and (ii) is equivalent to a strategy that seeks to maximize the expected log return. Further, Mossin (1968) demonstrates that for the log and power utility functions, maximizing the expected utility of return is equivalent to maximizing the expected utility of terminal wealth. Thus, for investors with log utility functions, the maximum geometric mean portfolio criterion is equivalent to the maximum expected utility of wealth criterion.

C. Desirable Properties of the Log Utility Function

39. For investors with log utility functions, the equivalence of the maximum geometric mean and the maximum expected log utility criteria is significant because log utility functions have many desirable properties. Among these properties are: (i) non-satiety; (ii) risk aversion; (iii) decreasing absolute risk aversion; (iv) constant relative risk aversion; (v) aversion to margin investing (that is, investing with borrowed money); and (vi) optimality of myopic decision making. Mossin (1968) demonstrates that the log and power functions are the only utility functions with all of these properties.

40. Non-satiety. Because the log utility function is increasing throughout its domain, investors with log utility functions always prefer more wealth to less, an attribute that economists refer to as "non-satiety." Although non-satiety would seem to be an obvious desirable property of a utility function, many utility functions do not possess this property, including the quadratic utility function.

41. Risk aversion. Consider the choice between (i) receiving \$W for certain and (ii) having a 50/50 chance of receiving either \$(W + C) or \$(W – C). Investors who choose alternative (i) over alternative (ii) are said to be risk averse, because these alternatives have the same expected value, but the second alternative has greater risk. Risk-averse investors choose alternative (i) because the difference in utility from receiving \$(W + C) rather than \$(W) is less than the difference in utility from receiving \$(W – C) rather than \$(W). That is, U (W + C) - U (W) < U (W) – U (W – C). Evidently, risk-averse investors have utility functions characterized by U″(W) < 0.[10] Since the second derivative of log W is $-1/W^2$, investors with log utility functions are risk averse.

42. Decreasing absolute risk aversion. Although all risk-averse investors have utility functions characterized by U″(W) < 0, some investors are more risk averse than others. The intensity of an investor's aversion to risk is determined by the curvature of the investor's utility function, where curvature is measured by the ratio of U″(W) to U′(W). Specifically, Pratt (1964) and Arrow (1965) define the coefficient of absolute risk aversion by the equation:

$$ARA(W) = -\frac{U''(W)}{U'(W)}. \qquad (27)$$

[10] We use the notation U″(W) to indicate the second derivative of the utility function U with respect to its argument, W.

For small gambles, Pratt and Arrow demonstrate that ARA(W) determines the dollar amount an investor is willing to pay to avoid a fair gamble with the possibility of either winning or losing a constant absolute dollar amount, C. They argue that absolute risk aversion should decrease with wealth because rich investors would be relatively unconcerned with losing an amount, C, that would cause great concern for poor investors. For the log utility function, ARA(W) equals 1/W. Thus, log utility functions imply that absolute risk aversion declines as wealth increases.

43. Constant relative risk aversion. Pratt and Arrow define the coefficient of relative risk aversion by the equation:

$$RRA(W) = -\frac{WU''(W)}{U'(W)}. \qquad (28)$$

For small gambles, they demonstrate that RRA(W) determines the fraction of wealth that an investor will pay to avoid a fair gamble with a possibility of winning or losing a specific fraction, C/W, of wealth. Economists generally believe that relative risk aversion should remain constant as wealth increases. This belief is consistent with the evidence that interest rates and risk premia have remained constant as average wealth has increased over time. Since RRA(W) equals 1 for the log utility function, log utility functions display constant relative risk aversion.

44. Aversion to investing on margin. Investors can frequently enhance their expected return on investment by investing on margin. However, margin investing is considered to be risky for individual investors because it can greatly increase both the variability of return on investment and the probability of bankruptcy. Investors with log utility functions are averse to margin investing because margin investing increases the probability that wealth will be less than some small value ε greater than zero; and their utility of wealth approaches minus ∞ as W approaches zero.

45. Optimality of myopic decision making. As noted above, lifetime portfolio selection is generally a complex problem that, because of its dynamic interdependence, can only be solved through sophisticated dynamic programming procedures. However, Mossin (1968), Samuelson (1969), and Merton (1969) demonstrate that investors with either log or power utility functions can solve their lifetime portfolio selection problem one period at a time. For these investors, the decision that maximizes the expected utility of wealth at the end of period t is the same as the t^{th} period decision resulting from a dynamic optimization procedure that considers the effect of the individual's t^{th} period decision on all future decisions. Myopic decision making is a highly desirable property of utility functions because it allows analytical solutions to problems that would otherwise be impossible to solve.

D. Solving the Geometric Mean Portfolio Problem

46. An optimal geometric mean portfolio consists of a set of securities, i = 1, … N, and the optimal proportion of wealth, X_i, to invest in each security. Let $R_i = (1 + r_i)$ denote the return on security i. Then the optimal geometric mean portfolio can be found by solving the following optimization problem:

$$\begin{aligned} &\text{Maximize } E\left[\log \sum_{i=1}^{N} R_i X_i\right] \\ &\text{with respect to } X_1, \cdots, X_N \\ &\text{subject to } X_i \geq 0, i = 1, \cdots, N \\ &\sum_{i=1}^{N} X_i = 1. \end{aligned} \qquad \textbf{(29)}$$

47. Vander Weide, Peterson, and Maier (1977) establish conditions required for the existence of a solution to the geometric mean portfolio problem and provide computational methods for finding exact solutions when solutions do exist. Maier, Peterson, and Vander Weide

(1977) examine the solutions to a relatively large number of simulated geometric mean portfolio problems obtained with the aid of a numerically efficient nonlinear programming code embedded within a partitioning algorithm. They find that the number of risky securities in an optimal geometric mean portfolio depends on one's expectations concerning future market conditions and on the conditions under which borrowing is permitted. When borrowing is not permitted, the investor who believes the market will fall should invest in just one security; the investor who believes the market will remain unchanged should diversify among two securities; and the investor who believes the market will rise should diversify among four to seven securities.[11]

48. When borrowing is allowed, the geometric mean portfolio problem must be modified to assure that the investor will not go bankrupt. Avoidance of bankruptcy can be accomplished by requiring the investor to withhold sufficient capital from investment to cover interest and principal payments on the borrowing. In the modified geometric mean portfolio problem, the investor who believes the market will rise should choose the same securities in the same relative proportions as when no borrowing is allowed. Furthermore, the individual characteristics of securities contained in optimal geometric mean portfolios also depend on one's assumptions about market conditions and the availability of borrowing. If a rising market is anticipated, the investor should invest in securities for which β_i and σ_i are large, and for which α_i is small. If the market is expected to decline, the investor should invest in stocks with high α_i and low β_i and σ_i.

49. Maier, Peterson, and Vander Weide (1977) also describe several heuristic portfolio building rules that provide near-optimal solutions to the geometric mean portfolio problem, including a geometric mean rule, a reward-to-variability rule, a reward-to-non-

[11] These numbers of securities are obtained under the assumption that the investor has 100 securities from which to choose. If the investor can choose among a greater number of securities, the optimal number to hold is likely to increase.

diversifiable variability rule, and a Kuhn-Tucker rule. Each rule follows the same principle: rank each security on the basis of one criterion, and then allocate equal dollar amounts to several of the top-ranked securities. They find that the geometric mean rule, the reward-to-variability rule, and the Kuhn-Tucker rule provide reasonable approximations to the returns on the optimal geometric mean portfolio.

50. Of course, the geometric mean portfolio problem cannot be solved without appropriate data inputs. Maier, Peterson, and Vander Weide (1977) note that the data inputs to the geometric mean portfolio problem can be estimated by assuming that the distribution of the holding period return, R_i, is related to a market index, I, through the equation:

$$\log R_i = \alpha_i + \beta_i I + \varepsilon_i, \qquad (30)$$

where I is defined as the expected value over all securities of the logarithm of the holding period return, α_i and β_i are constants, and ε_i is a normal random variable with mean zero and variance σ_i^2. The index I is considered a normal random variable whose parameters are chosen subjectively by the investor. Maier, Peterson, and Vander Weide (1982) develop an empirical Bayes estimation procedure for obtaining a simultaneous estimate of the three market model parameters of Equation (30) that makes use of more information than other estimates described in the literature.

E. Relationship between the Maximum Geometric Mean Return and the Mean and Variance of Return on a Portfolio

51. The geometric mean portfolio strategy is specifically designed for investors who wish to maximize their long-run wealth. Since the "long run" may be many years in the future, however, and mean-variance efficient portfolios have desirable short-run properties, it is natural to inquire whether the maximum geometric mean portfolio is mean-variance efficient.

Markowitz (1959) and Young and Trent (1969) address this inquiry by examining the expected value of several Taylor series approximations of either E log R or G. In discussing their methods and results, we will use the following notation:

μ_1	=	E(R)	=	the expected value or first moment of the probability distribution of R,
μ_2	=	$E(R- \mu_1)^2$	=	the variance or second central moment,
μ_3	=	$E(R- \mu_1)^3$	=	the skewness or third central moment, and
μ_4	=	$E(R- \mu_1)^4$	=	the kurtosis or fourth central moment.

52. The Taylor series approximation of log R centered around the mean value, μ_1, of R is given by:

$$\log R = \log \mu_1 + \frac{R-\mu_1}{\mu_1} - \frac{(R-\mu_1)^2}{2\mu_1^2} + \frac{(R-\mu_1)^3}{3\mu_1^3} - \frac{(R-\mu_1)^4}{4\mu_1^4} + \cdots \quad (\mathbf{31})$$

Taking expectations of both sides of Equation (31), and noting that E $(R - \mu_1) = 0$, we then have:

$$\mathrm{E}\log R = \log \mu_1 - \frac{\mu_2}{2\mu_1^2} + \frac{\mu_3}{3\mu_1^3} - \frac{\mu_4}{4\mu_1^4} + \cdots \quad (\mathbf{32})$$

53. Equation (32) provides several important insights about the relationship between the maximum geometric mean return and the mean and variance of return on a portfolio. First, if the third and higher moments of the probability distribution of R are "small" in relation to the first moment, E log R can be reasonably approximated by the expression:

$$\mathrm{E}\log R = \log \mu_1 - \frac{\mu_2}{2\mu_1^2}. \quad (\mathbf{33})$$

Second, if Equation (33) is a reasonable approximation for E log R, the geometric mean portfolio will be approximately mean-variance efficient because E log R will be maximized when the mean, μ_1, is maximized for any value of variance, μ_2, and the variance, μ_2, is minimized for any value of mean, μ_1. Third, if the third and higher moments of the probability distribution for R are

not "small" in relation to the first moment, the geometric mean portfolio may not be mean-variance efficient. An example where the geometric mean portfolio is not mean-variance efficient is provided by Hakansson (1971).

54. To test whether the maximum geometric mean portfolio is approximately mean variance efficient, Markowitz (1959) examines the ability of two geometric mean approximations to E log R to predict the actual geometric mean return on nine securities and two portfolios over the period 1937 to 1954. The two geometric mean approximations include:[12]

$$G(1) = \mu_1 - \frac{\mu_1^2 + \mu_2^2}{2}, \text{ and}$$

$$G(2) = \log \mu_1 - \frac{\mu_2}{2\mu_1^2}.$$

He finds that G(1) consistently underestimates the geometric mean return on the nine securities and two portfolios over the period, with an average error of eight percent. However, G(2) performs significantly better than G(1). It slightly overestimates the actual geometric mean return with an average error of only 1.7 percent. From his analysis of these approximations, Markowitz suggests that G(2) be used to estimate the geometric mean return for each portfolio on the mean-variance efficient frontier. He advises investors never to choose portfolios on the mean variance efficient frontier with greater single-period means than the optimal geometric mean portfolio because such portfolios will have higher short-run variance than the optimal geometric mean portfolio and less wealth in the long run.

55. Using methods similar to Markowitz, Young and Trent (1969) empirically test the ability of five geometric mean approximations to predict the actual geometric mean return on

[12] G(1) is derived from a Taylor series approximation centered on R = 1, while G(2) is the approximation shown in Equation (33).

233 securities and various portfolios based on these securities. The five geometric mean approximations include:[13]

$$G(1) = (\mu_1^2 - \mu_2)^{1/2},$$

$$G(2) = \mu_1 - \frac{\mu_2}{2\mu_1},$$

$$G(3) = \mu_1 - \frac{\mu_2}{2},$$

$$G(4) = \mu_1 - \frac{\mu_2}{2\mu_1} + \frac{\mu_3}{3\mu_1^2}, \text{ and}$$

$$G(5) = \mu_1 - \frac{\mu_2}{2\mu_1} + \frac{\mu_3}{3\mu_1^2} - \frac{\mu_4}{4\mu_1^3}.$$

Using monthly holding period returns for the time period January 1957 to December 1960 and annual holding period returns for the period January 1953 to December 1960, they demonstrate that geometric mean approximations such as G(2) and G(3), based only on the mean and variance of the probability distribution of R, provide predictions of geometric mean returns that differ on average from actual geometric mean returns by 0.5 percent. Thus, for their data set, we may conclude that maximum geometric mean portfolios are highly likely to be mean-variance efficient.

F. Comments on the Geometric Mean Portfolio Model

56. The geometric mean portfolio strategy is designed for investors who seek to maximize the expected value of their wealth in the long run. However, Merton and Samuelson (1974) demonstrate that maximizing the expected value of long-run wealth is not the same as maximizing the expected utility of long-run wealth. Since wealth at the end of a typical lifetime

[13] These approximations are derived from the Taylor series expansion of G centered around the mean value of R.

is variable, investors who are more risk averse than investors with log utility functions may prefer an alternative investment strategy that provides a stronger hedge against values of wealth that are less than the expected value of long-run wealth.

IV. Lifetime Consumption-Investment Model

57. The mean-variance and geometric mean portfolio models are designed to help investors choose the optimal proportions of wealth to invest in each security, based only on information regarding the probability distributions of returns on securities. If the probability distributions of returns are assumed to be independently and identically distributed, these models will recommend that the proportion of wealth invested in each security remain constant over the investor's lifetime. However, a constant proportion investment strategy is inconsistent with conventional wisdom that investors, as they age, should lower the proportion of wealth invested in risky stocks versus less risky bonds. The lifetime consumption-investment model is designed to help investors understand the conditions under which their optimal investment policy might change over their lifetimes, even if their probability beliefs remain constant.

58. Interest in lifetime consumption-investment models began in the late 1960s. Important early papers include Samuelson (1969), Merton (1969), Mossin (1968), and Hakansson (1969, 1970). Important later papers include Viceira (2001), Heaton and Lucas (2000), Koo (1998, 1999), Campbell, Cocco, Gomes, and Maenhout (2001), Bodie, Merton, and William Samuelson (1992), and Campbell and Cochrane (1999). Campbell and Viceira (2002) contains an excellent discussion of lifetime consumption-investment models, as well as a review of the literature on this important topic.

A. The Standard Lifetime Consumption-Investment Model

59. Consider an individual who must choose the amounts to consume, C_t, the fraction of wealth to invest in risky assets, w_t, and the fraction of wealth to invest in a risk-free asset, $(1 - w_t)$, at the beginning of each period (t = 0, 1, …, T). Assume that the individual's goal is to maximize the expected present value of the utility from lifetime consumption and that wealth must be either consumed or invested in each period. Let Z_t denote the random return on the risky asset, ρ the investor's discount rate, and r, the return on the risk-free asset. Then, the individual's standard lifetime consumption-investment problem can be stated as:[14]

$$\begin{gathered} \text{Max } E\left[\sum_{t=0}^{T}(1+\rho)^{-t}U(C_t)\right] \\ \text{with respect to } C_t, w_t \\ \text{subject to } C_t = \left[W_t - \frac{W_{t+1}}{(1+r)(1-w_t)+w_t Z_t}\right] \\ W_0 \text{given, } W_{T+1} \text{ prescribed.} \end{gathered} \tag{34}$$

B. Analysis of the Optimal Lifetime Consumption-Investment Strategy

60. The standard formulation of the lifetime consumption-investment problem is difficult to solve without some simplifying assumptions. In his first paper on this subject, Samuelson (1969) assumes that (i) the individual's utility function displays constant relative risk aversion, that is, the utility function is either a log or power function; and (ii) the probability distribution for Z_t is independently and identically distributed. To his surprise, he finds that the optimal proportion to invest in the risky asset is constant under these assumptions. Thus, under the standard assumptions, the lifetime consumption-investment model produces the same

[14] This formulation is taken from Samuelson (1969).

constant proportion recommendation as the mean-variance and geometric mean models. Merton, Leland, Mossin, and Hakansson reach similar conclusions.

61. However, Samuelson (1989), Bodie, Merton, and William Samuelson (1992), and the authors of later papers cited above, demonstrate that when the standard assumptions of the lifetime consumption-investment model are modified to include non-tradable human wealth,[15] subsistence levels of consumption, and mean-reverting probability distributions of returns, the conclusion that the percentage invested in risky assets is constant must be modified. Since the literature on the effect of these additional variables on the optimal solution to the lifetime consumption-investment problem is complex, we limit our discussion here to a brief summary of relevant conclusions.

62. Non-tradable human wealth. The effect of human wealth on an individual's optimal investment strategy depends on whether human wealth is riskless or risky. Assume first that human wealth is riskless, that is, that the present value of an individual's future income is certain. Since riskless human wealth is equivalent to an implicit investment in a riskless asset, the investor should adjust the proportion of financial wealth, F_t, invested in risky assets to reflect the investor's implicit additional holding of riskless assets. When human wealth is riskless, Campbell and Viceira demonstrate that the optimal proportion of financial wealth, F_t, to invest in risky assets is an increasing function of the ratio of human wealth to financial wealth, H_t/F_t. This ratio will typically vary over an individual's lifetime.

63. For young investors, the ratio of human wealth to financial wealth will typically be high because the young investor (i) can expect to earn labor income for many years to come;

[15] Human wealth, H_t, reflects the expected present value of an individual's future income. Human wealth is non-tradable because the legal system forbids trading in claims on an individual's future income. Financial wealth, F_t, reflects the current market value of an individual's financial assets, that is, stocks and bonds. Total wealth, W_t, is equal to H_t plus F_t.

and (ii) has not had much time to accumulate financial wealth. Thus, young investors should allocate a relatively large percentage of financial wealth to risky assets. In contrast, for investors nearing retirement, the ratio of human wealth to financial wealth will typically be low. Thus, when human wealth is riskless, the percentage of financial wealth invested in risky assets should decline with age.

64. Assume now that labor income, and hence human wealth, is risky. If labor income is uncorrelated with the return on risky assets, the investor with human wealth should still invest a greater percentage of financial wealth in risky assets than the investor without human wealth. However, the percentage invested in risky assets should decrease with increases in the variance of labor income, that is, investors with high variance in labor income should reduce the percentage of financial wealth invested in risky assets to hedge some of the risk of their labor income.

65. If, on the other hand, labor income is perfectly positively correlated with the return on one or more risky financial assets, human wealth is an implicit investment in these financial assets. In this case, the investor should either increase the percentage of financial wealth invested in the riskless asset or diversify into risky assets that are uncorrelated with labor income. This latter conclusion applies to all individuals who hold a high percentage of financial wealth in the stock of their employer.

66. Human wealth also affects the optimal percentage of financial wealth to invest in risky assets through the investor's ability to vary his or her work effort. If the investor can increase work effort to offset losses on financial assets, the optimal percentage of financial wealth to invest in risky assets will increase.

67. Subsistence levels of consumption. The optimal percentage of financial wealth to invest in risky assets also depends on the investor's desire to maintain a minimum level of consumption. A minimum level of consumption may be thought of as negative income because a certain part of income must be set aside to assure the minimum level of consumption. Samuelson (1989) establishes that as the investor nears retirement, the investor should increase the allocation of financial wealth to risk-free bonds in order to assure a minimum level of consumption in retirement. The shift towards risk-free bonds arises as a result of the investor's need to provide a steady income stream in retirement to cover the minimum level of consumption. However, Merton (1969) notes that young investors may also have a need to assure a minimum level of consumption in the face of uncertain human and financial wealth. He establishes that this need would also shift the optimal portfolio of young investors toward riskless bonds. Constantinides (1990) and Campbell and Cochran (1999) analyze the case where the minimum level of consumption itself may depend on either the individual's prior consumption habits or the consumption norms of society.

68. Mean-reverting probability distribution of returns. Samuelson (1989) demonstrates that when asset returns are mean reverting, investors with long investment horizons should invest more in risky assets than investors with short investment horizons. Campbell, Cocco, Gomes, Maenhout, and Viceira (2001) show that if asset returns are mean reverting, investors should reduce the percentage of financial wealth invested in risky assets when the returns on risky assets have recently been above the long-run mean return and increase the percentage of financial wealth invested in risky assets when returns on risky assets have recently been below the long-run mean return. Thus, investors who believe that returns on risky assets

are mean reverting should also vary the percentage of financial wealth invested in risky assets with the status of the capital markets.

Effectiveness of regulation in the electric utility industry

Francis Tapon and James Vander Weide

In recent years, regulation has come under increasing criticism. It is argued that regulation is ineffective because the regulators are captured by the industry that they are supposed to regulate. Capture results from frequent contact in regulatory hearings and from the realization of both the industry and the regulator that they share common goals. Thus, it may be contended that regulation does not affect significantly the behavior of the regulated industry.

In a recent article, Joskow expounds the hypothesis that regulatory commissions only regulate the profits of firms attempting to raise prices through the regulatory process [8, p. 121]. According to Joskow a strict regulatory constraint exists only for those firms actually engaging in the formal hearing process by seeking rate increases. Firms which can increase their profits without increasing prices tend, within rather wide boundaries, to be left alone by the regulatory authority. (They will not in general be called for a forced regulatory review and a forced price reduction [8, p. 123]). This hypothesis is tested by using data from electric public utilities in the United States. The theorem on which much of the work is based is derived from the Averch and Johnson model [1]. This theorem characterizes the type of bias induced by regulation and postulates that the profit-maximizing regulated firm employs a capital-labor ratio which is greater than one consistent with cost minimization for its level of output. Therefore, it can be inferred that firms which are heavily constrained by regulation (i.e., firms which attempt to raise prices) most likely look for ways to circumvent regulation, and, hence, are most likely to exhibit regulatory bias. More specifically, firms operating at or close to their allowed rate of return boundary because they recently went through the regulatory process face a regulatory constraint and may exhibit an Averch-Johnson type input distortion. These firms are called small-spread firms because the difference between the implicitly allowed rate of return (or earned rate of return) and the firm's cost of capital is small. The regulatory process brings earned rates of return in line with prevailing allowed rates of return which are themselves set equal to the firm's cost of capital.[1] On the other hand, firms operating far above the allowed rate of return boundary because they are ignored by the regulatory authorities are effectively unregulated, and, hence, have an incentive to minimize costs. These firms are called large-spread firms because the difference between the implicitly allowed rate of return (or earned rate of return) and the firm's cost of capital is large.

The Averch-Johnson hypothesis has been tested empirically in four recent studies. Courville [4] and Spann [18] find a significant Averch-Johnson effect; Boyes [3] and McKay [13] do not. The results of this study suggest that input distortions can occur in limited circumstances, but they are not as prevalent as Courville and Spann would have us believe.

Choice and stratification of sample

Since the capital-labor ratio in the production function for electricity is variable only in the planning stage of plant additions, the sample is confined to all newly constructed plants in the U.S. between 1960 and 1967. This makes a total of 90 plants. The study considers plant data only from privately-owned electric utilities. Municipally-owned, cooperative, and TVA plants are excluded because they are not

Dr. Tapon is assistant professor of economics at the University of Guelph in Ontario, Canada; Dr. Vander Weide is associate professor of economics in the department of management sciences at Duke University in Durham. The authors would like to thank two anonymous referees for helpful comments.

1. When the allowed rate of return is not always strictly enforced by the regulatory authorities, some firms are able to earn considerably more than this rate over long periods of time. Therefore, in this paper, the rate of return actually earned by a firm is considered to be the rate of return implicitly allowed by the regulatory authorities (by their lack of intervention).

subject to the same type of rate-of-return regulation as are privately-owned firms which supply nearly 80 percent of the total supply of electricity in the U.S.

The period 1960–1967 was chosen for the sample for three main reasons. First, only in 1961 did the Federal Power Commission [20] begin reporting the earned rates of return for 163 privately-owned electric utilities with sales of two million kilowatt-hours or more. Second, the time period covered in the sample should represent one of relative stability with regard to technological progress in electricity generation which is verified by Hughes [7]. Third, many firms were able to earn substantially more than their cost of capital without having to cut prices. Thus, this particular time period enables one to distinguish between firms which are free of regulatory control and firms which are not. This fact is crucial for the stratification of the sample.

Observations on all newly-constructed steam-electric plants in the U.S. are taken from Federal Power Commission reports [20] and [21] during the first year in which a plant operated for a sufficiently continuous period and with the same equipment (i.e., no additions or deletions of units) in order to have a recorded plant factor. Thus, each plant appears usually only once in the sample, and the year of observation generally is the year following construction of the plant. In most cases a year is sufficient for a new plant to attain its normal or planned level of output. In certain cases, the capacity of some plants was increased substantially (i.e., by more than 50 percent) after the plants were first recorded in the sample. In such cases, these plants were in effect new and, consequently, they appear more than once in the sample. Interpretation of variables and sources of data are discussed in the Appendix.

The study proposes to stratify the sample into utilities with a large spread between the allowed rate of return and the cost of capital and those with a small spread. Firms which requested a rate increase in the current year or in the previous two years are classified as small-spread firms. Firms which did not seek a rate increase in the current year or in the previous two years are classified as large-spread firms.[2,3] The necessary information on the filing of rate increases was obtained from Public Utilities Reports [16]. The validity of the classification was checked by computing, for all firms in each year in the period 1960–1967, the difference between the allowed rate of return and the cost of capital (proxied by the average yield on AAA bonds in the electric utility industry; see Miller and Modigliani [14]).[4] In the case of the large-spread subsample, the average difference in the period 1960–1967 was 2.25 percent; in the case of the small-spread subsample, the average difference in the period 1960-1967 was .866 percent. All but three firms in the total sample earned rates of return in excess of the cost of capital.[5] With a few exceptions, most firms in the large-spread subsample earned rates of return in excess of

2. The choice of three years before the operation of a plant may appear to some to be unrealistically short. This choice of stratification is suggested by Joskow [8, p. 121]; it is used in this study to test Joskow's proposition on the effectiveness of regulation in this industry.

3. One referee has suggested that since the plants considered have a lead time of more than three years from planning to operation, little reason exists to assume that the firm's decision to overcapitalize is affected by the status of the firm, before it went into operation, vis-a-vis the regulatory authorities. It can be argued that it would have been better to examine whether a firm requested a rate increase in the year (or previous two years) before a plant construction was planned. Unfortunately, this idea could not be investigated because the information on the date of first announcement of each plant in the sample could not be found. The necessary statistics (see Appendix) were likewise unobtainable. Having said this, two points should be noted: first, that the plant which is planned is not necessarily the one actually constructed; and second, that the sample stratification procedure is biased against confirming the hypothesis being tested. A firm mistakenly included in the small-spread subsample may show no Averch-Johnson input distortion, thus leading to a rejection of the hypothesis. Likewise, a firm mistakenly added to the large-spread subsample may show Averch-Johnson input distortion, again invalidating the hypothesis.

4. The authors recognize that the average cost of capital includes an equity component which is ignored here. Measuring the actual cost of equity capital is controversial, and no generally accepted procedure exists. However, Miller and Modigliani [14] have found that the movements of their estimates of the cost of capital in the electric utility industry conform quite closely with the average yield on AAA bonds in the industry. By choosing the average yield on AAA bonds, the study underestimates slightly the average cost of capital of electric utilities in the sample; but at the same time, the study establishes a uniform lower bound for the cost of capital of each utility in the sample. This procedure is followed by other authors (Courville [4] and Sankar [17]).

5. The exceptions were Public Service Company of New Hampshire, Southern California Edison Company, and Consolidated Edison Company of New York. As their earned rates of return were very close to the cost of capital for that year, these firms were kept in the sample.

TAW_R_GOCDR1#80Attachment
Page 676 of 739

seven percent. Most firms in the small-spread subsample earned rates of return almost equal to or less than seven percent. From the sample of 90 plants, two subsamples were obtained: 49 plants for the large-spread firms, and 41 plants for the small-spread utilities.

Estimation of a production function of electricity generation

In order to conduct a test of the hypothesis cited above, a production function is estimated for electricity generation. An approach pioneered by Courville [4] is followed. However, this study improves upon Courville's by recognizing the endogenous character of the firm's inputs. Courville assumes implicitly that the firm's inputs are exogenous variables and estimates his single equation model by *OLS*. Therefore, his estimates show simultaneity bias.

The question arises concerning which form of production function best describes the electricity generating process. No consensus exists on this point; various authors have used either the Cobb-Douglas, C.E.S., generalized C.E.S., transcendental-logarithmic, or Leontieff production functions. A study of overcapitalization in the production of electricity should take into account a major characteristic of this process—the existence of possibilities of factor substitution (in the ex-ante sense) between fuel and capital. This characteristic has been recognized by Nerlove [15] and by Dhrymes and Kurz [5] who use production functions allowing substitution between fuel and capital. This consideration is the determining factor in the choice of the Cobb-Douglas production function. Other advantages of the Cobb-Douglas production function are that it is linear in the logarithms and, consequently, easy to estimate, and that it does not seem to violate unduly the real world conditions of electricity supply.[6]

A Cobb-Douglas production function is postulated of the form:

$$Q_i = AK'^{a_1}_i F^{a_2}_i L^{a_3}_i e^{u}_i$$

where

Q_i = annual output of plant i in million kilowatt-hours

K'_i = annual quantity of capital services in thousands of dollars

This flow variable appears as an input in the production function. Since K'_i cannot be observed, it is assumed that the following relationship exists between K'_i, K_i and the plant factor (or rate of utilization of capacity):

$$K'_i = PF_i^{b_1} K_i^{b_2}$$

where

PF_i = plant factor or rate of utilization of capacity of plant i during the year, measured as a percent of maximum output.

K_i = structures and equipment capital of plant i measured in thousands of constant dollars. This formulation attempts to determine which part of total plant investment constitutes the productive capital input. A major feature of electricity production is that the rate of operation varies over time and, thus, affects the productivity of factor inputs. In order to measure productive capital services, the engineering concept of plant factor is introduced. Hence, the production function is specified to allow for variations in the rate of output.

L_i = labor input measured in average number of workers employed by plant i during the year.

F_i = annual fuel consumption measured in 10^7 BTU equivalents.

u_i = random error term assumed to be normally distributed with mean 0 and variance σ^2 such that $E(u_i, u_j) = 0$, $i \neq j$.

The results of the studies by Komiya [10], Dhrymes and Kurz [5], and engineering obser-

6. The Cobb-Douglas production function is used because it yields good results, and because, in the authors' opinion, the extra effort of estimating a C.E.S. production function is not worthwhile in this case. Maddala and Kadane [11] show that in the cases where the distributions of L, K, and F are independent, lognormal, and similar, the use of a *CD* function to estimate the returns to scale parameters do not result in much bias. These conditions are satisfied approximately by the data in the sample. Other studies attempting to test the *A-J* hypothesis empirically have used a variety of production functions. Courville [4] reports investigating alternative functional forms, but he could not reject the null hypothesis that the relevant technology can be summarized by a *CD* formulation. Hayashi and Trapani [6] use both *CD* and *CES* type production functions, with the former providing somewhat better results.

vations suggest that the labor input remains limitational in electricity generation and that the only substitutional processes are between fuel and capital. Labor's main functions are in operational, supervisory maintenance, clerical and office-type activities. The study assumes, as do Dhrymes and Kurz, that a certain amount of labor must be present before generation can begin, and that labor requirements increase with output, with the number of generating units, and/or with capital. Labor enters the production function in a fixed proportion which the following production function of the Dhrymes and Kurz type illustrates:

$$(1) \quad Q = min[\ell(L); AK'_i{}^{a_1}F_i{}^{a_2}].$$

It is assumed that the necessary amount of labor L to produce Q is available so that no optimization takes place with respect to labor. This entails that $\ell(L)$ exceeds the second term on the right and that optimization occurs only with respect to capital and fuel. One can therefore write:

$$(2) \quad Q = AK'_i{}^{a_1}F_i{}^{a_2}e^{u_i}.$$

It should be recognized that capital and fuel inputs may not be determined exogenously as was assumed implicitly in equation (1). Instead, these inputs should be determined jointly by the plant's efficiency, its level of output, and the costs of its factor inputs. To avoid specification bias, these variables should be estimated separately by regressing them on other exogenous variables in the system.

In order to test for overcapitalization in the production process, it is necessary to know the conditions characterizing a proper utilization of inputs. It has been shown elsewhere (Averch and Johnson [1]) that the necessary conditions required for a profit maximizing combination of capital and fuel are:

$$(3) \quad \frac{F_k}{F_f} = \frac{d(l) - \lambda q(s + \delta)}{f(1 - \lambda)},$$

where

$F_K \equiv$ the marginal physical product of capital,
$F_f \equiv$ the marginal physical product of fuel,
$d(l) \equiv$ the shadow rental price of capital,
$\lambda \equiv$ a Lagrange multiplier,
$q \equiv$ the reproduction price of a unit of capital equipment (measured in \$ per unit),
$s \equiv$ the allowed rate of return,
$\delta \equiv$ the rate of depreciation of physical capital,
$f \equiv$ the price of fuel.

The marginal physical products of capital and fuel from the production function equation (2) are now derived and substituted into equation (3). Note that equation (2) can be written as:

$$(4) \quad Q_i = AF_i{}^{a_3}PF_i{}^{a_3}K_i{}^{a_4}e^{u_i}$$

where

$$PF_i{}^{a_3} = PF^{b_1 a_1}$$

$$K_i{}^{a_4} = K_i{}^{b_2 a_1}.$$

Thus,

$$(5) \quad \frac{a_4}{a_2}\frac{F}{K} = \frac{d(l) - \lambda q(s + \delta)}{f(1 - \lambda)}.$$

Taking natural logarithms of both sides of equation (5), and transposing terms, one obtains:

$$(6) \quad ln\ F = ln\frac{d(l) - \lambda q(s + \delta)}{f(1 - \lambda)} + ln\ K - ln\ a_4 + ln\ a_2$$

In equation (6), the factor input price ratio is an exogenous variable since it is assumed that inputs are obtained in competitive markets. Notice that the Lagrange multiplier λ enters the factor input price ratio. The variable λ is an exogenous variable, but no observations are available for it. It is known, however, that it can be constrained between zero and one in the cases being considered (see Baumol and Klevorick [2]). The variable λ can be further constrained using the empirical data of the sample.

In order to derive an equation for K, a procedure first proposed by Dhrymes and Kurz is followed. Assume that $ln\ K$ is related functionally to the logarithms of the factor price ratio and the other exogenous variables in the system as they appear in equation (6). Assume further that this function for $ln\ K$ can be expanded in a MacLaurin series which is sufficiently approximated by, at most, its first degree terms. One obtains:

TAW_R_COCDR1#80Attachment
Page 678 of 739

$$(7)\quad \ln K = c_0 + c_1 \ln \frac{d(l) - \lambda q\,(s + \delta)}{f(1 - \lambda)} + c_2 \ln PF.$$

If equations (6) and (7) are viewed as stochastic relations, an error term can be added to each. Equations (4), (6), and (7) form a three-equation system. Since the sole interest is in estimating the Cobb-Douglas exponents of the production function (4) and the variances of these estimates, the study concentrates on this equation and estimates it with two-stage least squares.

The exogenous variables in the system are *PF* and the factor price ratio is

$$\frac{d(l) - \lambda q(s + \delta)}{f(1 - \lambda)}.$$

It was already noted that λ, the shadow cost of regulation, is exogenous but that the authors possess no observations on this variable. The variable λ is restricted to be between zero and one and is expected to vary from firm to firm.[7] One does not expect the coefficient estimates of the production function, equation (4), to be significantly affected by the choice of λ; however, because λ is not a direct component of the production function itself, it only affects the production function through the other equations in the system. The production function describes the same physical generating process regardless of the presence or absence of rate of return regulation. Thus, the estimates of the production function's parameters reflect only this fact of life, whether or not the amount of investment by the firm in durable physical capital is unduly large in the light of factor prices prevailing in the market. As long as the firm employs the minimum fuel and labor inputs necessary with the fixed capital to produce the observed output, the production function may be estimated. It may be argued that since the estimation of the production function is based on data obtained from decisions based on financial factors, it is possible that the estimation of the production function be distorted by regulatory effects. The empirical results do not support this argument.

The production function equation (4) was estimated from the three-equation system using two-stage least squares. The exogenous variables in the system are

$$\ln PF,\ \ln\left[\frac{d(l) - \lambda q(s + \delta)}{f(1 - \lambda)}\right],\ OD,\ SOD$$

and the constant term $\ln A$. The necessary order condition for identification is satisfied since the number of exogenous variables excluded from equation (4) is greater than the number of endogenous variables included on the right-hand side of equation (4).

Table 1 presents the results of 2SLS estimation of production function equation (4) for different values of λ altered by increments of 0.05 between the values of 0.000 and 0.415.[8] As anticipated, the coefficient estimates for fuel and capital do not change much as λ varies. The coefficient estimate of fuel varies from 0.918 when $\lambda = 0.415$ to 0.920 when $\lambda = 0.000$. Likewise, the coefficient estimate of capital varies from 0.123 when $\lambda = 0.415$ to 0.127 when $\lambda = 0.000$. All the coefficient estimates are statistically significant at the five percent level with a two-tail *t* test. It also appears that R^2 at $\lambda = 0.415$ differs from R^2 at $\lambda = 0.000$ by only 0.002.

It is tempting to choose a best value of λ by using a goodness of fit criterion on the regression equation of the production function equation (4). Such temptation must be resisted because of the impossibility of verifying whether or not differences in R^2 are statistically signifi-

7. One can further restrict λ by using the marginal productivity condition for capital equation. If one assumes that the marginal revenue product of capital is positive, then it follows that:

$$\frac{d(l) - \lambda q(s + \delta)}{(1 - \lambda)} > 0 \text{ or } \lambda < \frac{d(l)}{max\ q\ (max\ s + \delta)}.$$

The sample data enables one to determine that $\lambda < 0.415$.

8. R^2 is obtained by an asymptotic test suggested by McElroy [12].

R^2 is given by the following formula:

$$R^2 = \frac{\hat{\delta}_j' R_j' N R_j \hat{\delta}_j}{Y_j' N Y_j}$$

where

$\hat{\delta}_j$ = a vector of *2SLS* estimators for the production function,

R_j = a matrix of the 90 observations on the included endogenous and exogenous variables,

$N = X(X'X)^{-1}X'\ [1 - 1/n\ \beta\beta']$ and $\beta\beta'$ is a (90 x 90) matrix of ones,

X = a matrix containing all exogenous variables in the system,

Y_j = a vector of 90 observations on the dependent variable.

Note: The numbers in parentheses under each estimate are the corresponding t statistics.

cant. Usually, when comparing R^2 values, a variable is added to a regression while keeping the same set of observations for the variables already included in the regression equation. This is not done here. The variable λ is varied by increments of 0.05. This means that as λ changes, the observations on the exogenous factor price ratio change. Therefore, R^2 values may not be compared since they pertain to equations obtained from a varying set of observations.

The study does not abandon this approach of estimating a production function (rather than estimating its dual, a cost function as shown by Nerlove [15]), because it provides results which seem plausible based on other grounds. For example, as expected, changes in λ affect negligibly the estimated parameters for *K, PF,* and *F;* the output elasticities of the various inputs are comparable to other estimates found in the literature.[9]

To conduct the tests described below [equation (9)], one chooses values of the coefficient estimates obtained with λ = 0.000, 0.200, 0.415. This procedure allows one to investigate the sensitivity of empirical results to alternative values of λ. The results are not changed in any way; i.e., the number of times the null hypothesis is rejected and not rejected is the same in all cases; only the range of values of the *t* statistic, equation (9) infra, varies slightly. Since the results of the production function estimation are insensitive to alternative values of λ, to conserve space the study reports only results where coefficient estimates with λ = 0.000 are used.[10]

Empirical results

Now that a particular form of a production function has been selected, the ratio of marginal productivities for each plant in the sample can be specified and written:

$$\frac{F_K}{F_F} = \frac{a_4}{a_2}\frac{F_j}{K_j}$$

9. Note that this particular problem is common in econometric work, and practitioners do not always rely on R^2 as a criterion of goodness of fit. The comparison of R^2 is not straightforward even in models involving such simple changes in the dependent variable as writing *lnY* instead of *Y*.

10. The relative insensitivity of the production function estimates to the value of λ does not imply that λ is in fact zero, i.e., that regulation is ineffective. The procedure requires a λ value in order to estimate the production function coefficients. It does not provide an efficient estimate of the actual value of λ.

All of the variables have been defined under "Choice and Stratification of Sample" and in the Appendix. The null hypothesis is thus:[11]

$$H_o : \frac{a_4}{a_2}\frac{F_j}{K_j} - \frac{d(I)_j}{f_j} = 0$$

or

$$(8) \quad H_o : a_4\frac{F_j}{K_j} - a_2\frac{d(I)_j}{f_j} = 0.$$

Fuel and capital, respectively F_j and K_j, are assumed to be non-stochastic. Thus, the null hypothesis is studied in the form of a t-test, and, consequently, one should also compute:

$$(9) \qquad t_j = \frac{\hat{a}_4\frac{F_j}{K_j} - \hat{a}_2\frac{d(I)_j}{f_j}}{\sqrt{\sigma^2}}$$

where

$$\sigma^2 = \sigma_{\hat{a}_4}^2\left(\frac{F_j}{K_j}\right)^2 + \sigma_{\hat{a}_2}^2\left(\frac{d(I)_j}{f_j}\right)^2 - 2\sigma_{\hat{a}_4\hat{a}_2}\left(\frac{F_j}{K_j}\times\frac{d(I)_j}{f_j}\right)$$

$\sigma_{\hat{a}_4}^2$ = estimated variance of $\hat{a}_4$

$\sigma_{\hat{a}_2}^2$ = estimated variance of $\hat{a}_2$

$\sigma_{\hat{a}_4\hat{a}_2}$ = estimated covariance of $\hat{a}_4$ and $\hat{a}_2$.

The figures for $d(I)_j$, f_j and K_j are all deflated. The number of degrees of freedom is computed as $n - k$, where n is the number of observations and k is the number of regressors in the estimated equation.

The interest of this study is only in a single-tailed test since it is testing for the possibility of overcapitalization. The region of rejection consists of low and negative values of t_j. This can best be seen when one looks at the alternative hypothesis:

$$(10) \quad H_1 : a_4\frac{F_j}{K_j} - a_2\frac{d(I)_j}{f_j} < 0.$$

Before conducting the t-tests of equation (9), note that the input distortion recognized in the regulatory theorems investigated here holds at each level of output or capacity. Therefore, first one must investigate whether or not the installed generating capacities of the plants in the two subsamples are independent of the allowed rates of return which constrain the parent firms. A second question concerns whether or not the rental prices of capital and the prices of fuel charged to the plants in the two subsamples are independent of the allowed rates of return of the parent firms. It could be argued that overcapitalization occurs within the small-spread subsample because low values of the allowed rate of return coincide in some way with low values of the rental price of capital or with high values of the price of fuel. These questions are investigated in Tapon [19] using variance tests, t-tests, and chi-square tests. It is shown that no difference exists between the installed generating capacity of the plants included in the two subsamples. There is also no relationship among the rental price of capital, the price of fuel, and the allowed rates of return to which each plant is subjected through its parent firm.

The null hypothesis given by equation (8) was tested for all 90 firms in the sample using the t-statistic shown in equation (9) and tables of Student's t distribution. The results of these tests are reported in Table 2 which shows that 24 of the 41 firms in the low-spread subsample chose input combinations that were inefficient in a least cost sense, while only 19 of the 49 firms in the high-spread subsample chose inefficient input combinations. The difference between these two proportions is significant at the 90 percent level using the usual test of significance of the difference between two proportions.[12] These results differ from those of Courville [4] who finds that he rejects the null hypothesis, equation (8), in the vast majority of cases (110 plants in his sample; 71 rejections at the 5 percent level, 76 rejections at the 10 percent level, for the vintage period 1960–1966). A possible explanation for the difference between his findings and those of this study is that Courville's estimates of output elasticities for the inputs may suffer from simul-

11. This formulation was first proposed by Courville [4].

12. Caution should be used in interpreting the study's results as well as those of Courville. The test used above does not discriminate among *A-J* effect, buying excess capacity (gold-plating), and dedication of a plant for peak versus base-load use. In the last case, plants that are shut on and off use more fuel per unit of capital than continuous base-load plants. To some extent, the method of choosing the sample takes some of these problems into account. Since a plant enters the sample only once during its first normal year of operation after construction, it can be assumed that it operated continuously because it embodies the more recent technology and is given priority in producing output.

Table 2
Results of the Test on the Effect of Regulation on the Plant Capital-Fuel Ratio According to Equation (9) for the Large-Spread and Low-Spread Subsamples, 1960–1967

Number of Plants in Each Subsample	High-Spread Subsample 49	Low-Spread Subsample 41
Number of times H_0 was rejected	19	24
Number of times H_0 was not rejected	30	17
Range of values of t_j	−17.5764 + 1.2143	−12.9758 + 1.1102

*The t-tests are single-tail tests conducted at the 5 percent level of significance.

taneity bias since he assumes implicitly that the inputs are exogenous variables.

The results reported in Table 2 seem to confirm the Joskow hypothesis that strictly regulated firms are most likely to exhibit an Averch-Johnson type input distortion. These results should disturb policy makers who feel comfortable with the current mode of regulatory control of public utilities. On the positive side, it is interesting to note that less than one-half of all the firms in the sample displayed the input inefficiency hypothesized by Averch and Johnson. The latter result is considerably more encouraging than that reported by Courville [4] and Spann [18].

In conclusion, it seems that rate of return regulation does not produce the empirical degree of inefficiency that some would suggest. It remains to be determined whether this result stems more from the ineffectiveness with which regulation is applied than from the fact that Averch and Johnson's famous overcapitalization theorem does not hold in the world of regulated utilities.

Data Appendix

Q = output measured in million kilowatt-hours.

C = installed generating capacity (nameplate rating in megawatts).

L = average number of workers

F = total fuel use in 10^7 British Thermal Units (BTU) equivalent.

PF = plant factor which is the average rate of annual utilization of the plant expressed as a percentage.

K_1 = equipment capital in thousands of constant dollars. The wholesale price index for electrical machinery and equipment was used as a deflator; 1957–1959 = 100.

K_2 = structures capital in thousands of constant dollars. The Handy-Whitman utility construction index was used as a deflator; 1957–1959 = 100.

K or q = total deflated cost of plant and equipment; K or $q = K_1 + K_2$.

f = price of fuel, which is computed by dividing the deflated fuel expenditures of a plant by the total fuel use in BTUs during the year of observation. The wholesale price index for fuels and related products was used as a deflator; 1957–1959 = 100.

$d(I)$ = rental price of capital. Since the authors have no observations on this variable apart from the total cost of a plant, it had to be computed. It is argued that this variable corresponds to the yearly outlay the plant manager would have to make to receive the services of capital existing in his plant. Consequently, the rental price of capital is the annual equivalent outlay to the purchase of a new plant every 35 years. (Thirty-five years is the period of depreciation employed by the F.P.C.) The total deflated cost of plant and equipment is thus divided by the present-value of one dollar received per period for 35 years and a

measure of $d(I)$ is obtained.[13] The interest rate used to determine the present-value of one dollar received per period should normally be the weighted average cost of capital for each firm in the sample. However, Miller and Modigliani [14] have found that the movements of their estimates of the costs of capital in the electric utility industry conformed quite closely with the average yield on AAA bonds in the industry (McElroy [12]). Although the average yield on AAA bonds slightly underestimates the cost of capital of electric utilities in the sample, it is used as a proxy measure of the cost of capital.

s = allowed rate of return. Earned rates of return for privately-owned electric utilities have been computed by the F.P.C. since 1961 (Sankar, [17]). Starting with 1963, a three-year average of earned rates of return is taken and used as measure of the allowed rate of return for each firm in the sample. For 1963, a two-year average is taken. For 1960 and 1961, the value of s in 1961 is taken.

OD and SOD = plant types which are: 1) conventional; 2) outdoor; 3) semi-outdoor; 4) outdoor boiler. $OD = 1$ if the plant is outdoor; $OD = 0$ if otherwise. $SOD = 1$ if the plant is semi-outdoor and outdoor boiler; $SOD = 0$ if otherwise. These exogenous dummy variables are included because the construction component of capital input can vary considerably according to location and weather conditions at the plant site. For example, in the South, a plant is frequently outdoor or semi-outdoor, whereas in the North, a plant is generally indoor. These factors affect the measure of capital input and should be reflected in the production function.

13. This method of computing the rental price of capital was first used by Courville [4].

REPLY TO AUCAMP

In our recent article [1] in this journal, we stated in the introduction that a portfolio selected to maximize the geometric mean return will "Maximize the probability of exceeding a given wealth level in a fixed amount of time." Donald C. Aucamp has pointed out to us that this is not true, at least not without further qualifications. A correct statement of the minimum time property can be found in Breiman [2]: as the "desired fortune x becomes infinite, . . . the expected time under Λ^* (the geometric mean strategy) to amass x becomes less than that under any other strategy." We note that the results of our paper are not compromised by the imprecision of our opening statement.

ESTIMATION AND SIMULATION

A number of papers on estimation procedures for simulation have been published in *Management Science* and related journals. I believe that many of these are on the wrong track. The purpose of this letter is to indicate what appear to be shortcomings in this literature and to suggest (imperfect) remedies.

I pose the following questions:

1. Is it dangerous to extrapolate comparative performance of estimators in idealized situations to their performance in realistic cases?
2. Is the emphasis on estimating steady-state behavior misplaced?

The answer to each of these questions is, in my opinion, "Yes!"

While acknowledging the danger, one can defend extrapolation from idealized models *provided* that the models have been carefully validated. The only way to do this statistically is to drive the real system and the model with identical inputs and then to compare the corresponding outputs, subjecting any discrepancies to rigorous tests. If this is feasible, fine. But often the real system has not yet been built or such comparisons are too expensive.

Much of the literature takes a different tack. Estimators are compared for very simple models, such as a queue with stationary Poisson input or a critical path network with just six arcs, with independently distributed lengths; but there is *no* specific real system in mind. It is usually the case that these models are gross simplifications of real systems and, without a concrete system, the concept of model validation becomes vacuous. This being the case, there is no statistical basis for extrapolating the performance in real systems. It can be (and has been) argued that idealized models should be used to screen techniques that supposedly reduce the variance of estimators. The trouble with this approach is that there are many *a priori* reasonable variance reduction techniques and combinations thereof and that the goal

General Telephone's Experience With a Short-Run Financial Planning Model

Effective use of financing alternatives is the responsibility of GTE treasurer Jerry Austin. Here, Austin and two Duke University professors outline GTE's time-sharing computer model.

by Jerry Austin, Dr. Steve F. Maier and Dr. James H. Vander Weide

In periods of high and rapidly fluctuating interest rates, wise cash management is especially important. Firms who continuously borrow in the short-term money markets can save 10-50 basis points in such periods through proper timing and choice of financial instruments. Here's how GTE's time-sharing computer model helps minimize interest costs.

The Company. General Telephone Company of the Southeast (GTSE), headquartered in Durham, N.C., provides telecommunication service in seven southeastern states. Effective use of the company's financing alternatives is the responsibility of GTE Treasurer Jerry Austin. Because of high interest rates, inflation, and the capital-intensive nature of the telephone communications industry, GTSE has turned aggressively to new financial decision-making techniques to reduce interest costs.

With few exceptions, GTSE is a net borrower of short-term funds, with commercial paper and master notes being the current least expensive sources. Quick and accurate comparisons of master notes and various maturities of commercial paper has typically been a difficult task, due primarily to the uncertainty of future interest rates, and the sheer number of financing alternatives available.

The Short-Run Financial Planning Model. Prior to the short-run financial planning model, the decisions about borrowing instruments were based primarily on past experience and discussions with the firm's commercial paper dealer. A detailed analysis was impossible because of the limited time available.

The financial planning model allows a cash manager to analyze, inexpensively and accurately, the interest costs of different financing alternatives. The cash manager simply inputs cash flow and interest rate forecasts into the model and in a few seconds, the model generates an optimal short-run financial plan, indicating the best borrowing instruments and the total interest cost.

After the optimal plan, a cash manager can use the model in two different ways to estimate returns and risks of each financial strategy.

First, he can eliminate one or more of the selected instruments, forcing the model to use another alternative. The interest cost of that alternative is then compared to that of the optimal plan.

Second, the cash manager can vary his cash flow and interest rate forecasts to determine the optimal plan's sensitivity to forecast variations. This process provides an estimate of the risk of each strategy.

Jerry L. Austin (left) is treasurer of General Telephone Co. of the Southeast, Durham, N.C. He also serves as a lecturer on finance in GTE's internal management training programs and has spoken before business organizations and university business schools. Austin also testifies as GTE's witness on rate-of-return and cost-of-capital before the public service commissions in the southeastern states where GTE operates. He holds a BA in accounting and economics from Michigan State University, E. Lansing, and an MBA in finance from Pace University, New York.

Drs. Steven F. Maier (center) and James H. Vander Weide (right) are associate professors in the Graduate School of Business Administration at Duke University, Durham, N.C. Both have been active in cash management research and consulting, and were co-founders of University Analytics, a major provider of cash-management services to the banking industry.

Input Requirements for the Model. The short-run financial planning model was especially designed to be user-oriented. All information is entered through a time-sharing conversation via computer terminal. Since data from previous runs is stored, the model is particularly easy to use. once the first case has run. Only data *changes* need be entered on subsequent runs.

The input is conveniently grouped into four types:

1. *Period Duration and Cash Flow Projection*

The cash manager must specify the number and length of each time period within the planning horizon. He is also asked to specify which cash flows will be expected at the beginning of each time period within the horizon. The current model specification allows for a maximum of 25 time periods, with no limitations about the length of these periods. Cash flows may be either positive or negative.

We have found that it is best to keep the first few periods in the time horizon relatively short. For example, it is frequently convenient to use daily periods for the first few days, followed by a three-day period corresponding to a weekend. Later periods can be longer, often a week or two. It is also helpful to have one final period of relatively long duration to give some weight to the firm's long-run cash flow and interest rate projections.

2. *Instrument Description*

The second input section represents a description of the available investment/financing instruments. Each instrument is described by name, maturity length, yield, and interest rate projection.

The maturity may be specified as a constant (a 91-day Treasury Bill would be specified as 91 days.) Since some financial instruments may be purchased to have the same yield, with a range of possible maturities, the model also permits the user to specify a range. For example, commercial paper with a yield of 9.5% could be specified to have a maturity of between 15 and 37 days.

The yield on an instrument is always computed as if the interest will be paid upon maturity. If the instrument was sold or bought at a discount, the discount rate can be specified and the model will automatically convert the discount rate of interest to the interest yield, as if the interest had been paid at maturity.

3 *Interest Rate Projections*

The cash manager can specify an interest rate projection, as either a single interest rate projection (and use it to modify the yields on a group of investment instruments) or he can specify an independent interest rate projection for each of his investment or borrowing instruments.

4. *Borrowing Limit*

The model allows a cash manager to limit the amount of borrowing or investment associated with one of the instruments. This limit allows him to incorporate judgements about the risk of various instruments, or to include company policy decisions.

Output Reports. The short-run financial planning model provides several types of output reports.

1. *Cost Summary*

The cost summary gives five types of information *for each period* (Exhibit 1):

- number of days
- cash flow projection
- marginal rate
- interest expense
- cumulative interest expense

The number of days in the period and the projected cash flow are user-specified. The marginal rate is the value of reducing the firm's borrowing in a given period, and this can help the firm determine whether it wishes to expedite some cash flows, or postpone the payment of specific payable items. The interest expense takes into account *all instruments purchased or sold* during the period, and *all instruments which were activated before the start of the period* and matured at some later date. A negative interest expense (one enclosed in parentheses) indicates interest earned. The cumulative interest expense is the interest expense for the current and all previous periods.

2. *Action Summary*

The action summary, (Exhibit 2) lists eight components for each instrument bought or sold:

- period in which the action is initiated
- instrument name
- type of action (buy or sell).
- action date
- maturity date
- amount of capital involved with the original purchase/sale of the instrument
- maturity value of the instrument
- yield of the instrument

An instrument is only listed in this report on the day the initial action is taken. The example in Exhibit 2, shows that a Master Note activated in period 6, day 71, matures on day 99. Since the Master Note has a fixed maturity of only one day, the note was "rolled over" 28 times in order for its maturity date to coincide with the decision date. "Rolling over" of short-term instruments is an automatic feature of the model. To obtain a list of both initial and concluding actions within a period, the detailed report is required.

The "action" column indicates, with a "B" or "S", whether the instrument was bought or sold. The action date is the first day of the period in which the instrument is activated and the maturity date is the day of maturity.

The instrument yield is set initially as part of the instrument's description and can be revised by an interest rate projection.

3. *Interest Rate Summary*

Exhibit 3 gives an example of the Interest Rate

The Optimal Short Term Financial Plan

Exhibit 1

COST SUMMARY

Period	Length	Cash Flow	Marginal Rate	Interest Expense This Period	Cumulative Interest Expense
1	4	$ 0.00	9.754%	$ 0.00	$ 0.00

Summary Report, showing in matrix form the yield of each instrument at the start of each period. The instruments are listed across the top of the matrix: the first four characters in the instrument name are used as an identifier. The first column in the matrix lists the starting day of the period, rather than the period number.

With this information, the cash manager can check how his interest rate projections have modified the yield on each instrument. If there was no projection for the instrument, the same yield will appear throughout the column.

4. *Input Summary*

The input summary lists the data in a particular model file, giving users a consolidated look at all additions and deletions made during a computer session. The report is available upon first entering the model, or as an option after solving the model, and includes information in four major input categories: period duration and cash flow projection; borrowing limit; instrument description; and interest rate projections.

5. *Detailed Output Report*

The detailed output report gives a complete statement of activity on a period-by-period basis. In addition to the period number, starting date, marginal rate of return, and cash flow projection, the report includes all maturing securities, new purchases and sales, and holdings at the close of the period. The following data is given for each instrument:

- instrument name
- action (bought or sold)
- action date
- maturity date
- amount
- maturity value
- current yield

Benefits from Using the Model. The short-term financial planning model has provided GTSE with important ways to use its cash resources efficiently.

First, the model makes a cash manager sensitive to variables which affect his day-to-day borrowing decisions, leading to increased awareness of economic trade-offs associated with short-run financial decision-making.

Second, the model provides a means of comparing alternative instruments on the basis of "effective" vs "posted" interest rates. This is especially important for GTSE because of its heavy reliance on commercial paper, which is quoted on a discount basis.

Third, the model helps the cash manager to quickly and efficiently make comparisons of borrowing instruments which have variable maturities, providing a quantitative measure and the expected value of different financing strategies. This important feature allows a cash manager to analyze risk/return relationships.

Finally, the model's flexibility allows identification of the strengths and weaknesses of the present cash management system and forecasting methods, and offers ways to improve.

The model has also proved to be a valuable teaching and budgeting aid by providing simple, effective ways of budgeting short-term interest payments within a particular cash flow and interest rate scenario. The model will also quickly measure the impact of cash flow/interest rate variances on total interest expense. As a teaching tool, the model illustrates basic techniques and gives users an appreciation for the investment/borrowing selection process.

In summary, the short-term financial planning model has allowed GTSE to quantitatively analyze a multitude of potential borrowing options in a timely fashion, in a way which was heretofore impossible. Through continual emphasis on the importance of good cash management, the model has provided an impetus for improving the overall cash management process.

Our Philosophy

To provide, through the "forum" concept, a useful medium for the exchange of current thoughts, questions and experiences of corporate executives in the cash management profession

The *Cash Management Forum* is published by The First National Bank of Atlanta for the benefit of financial managers throughout the country. Permission to reprint all or part of the *Forum* contents may be obtained from the editor.

A Unified Location Model for Cash Disbursements and Lock-Box Collections

Steven F. Maier
Duke University

James H. Vanderweide
Duke University

The benefits from an improved corporate cash management system generally stem from three sources. First, the firm can often achieve a considerable reduction in its collection float by locating lock-boxes in strategic customer areas and utilizing devices such as wire transfers to shorten the time between customer mailing and fund availability. Second, the firm can usually increase its disbursement float by choosing wisely the offices and banks from which it disburses. Finally, the firm can reduce the costs of banking services it receives by carefully setting the levels of its bank deposit balances. In this paper, we provide a brief review of the models that are currently available to analyze each of these areas, and then present a unified model which can be used to optimally design an entire cash management system.

THE LOCK-BOX LOCATION PROBLEM

It is well-known that corporate treasurers can sometimes significantly increase the amount of funds available for investment by locating check collection points, commonly called "lock-boxes," in one or more of the firm's major customer areas. The problem of locating those check collection points which minimize the value of uncollected funds can be formulated mathematically as follows:

(1) MINIMIZE
$$W = \Sigma_k \Sigma_m [p(q_{mk} + r_{mk}) + e_{mk}] \cdot Y_{mk} + \Sigma_k f_k^c \cdot Z_k^c$$

(2) s.t. $\Sigma_k Y_{mk} = b_m \quad \forall m$

(3) $\Sigma_m Y_{mk} \leq (\Sigma_m b_m) Z_k^c \quad \forall k$

(4) $Y_{mk} \geq 0, \; Z_k^c = 0 \text{ or } 1 \quad \forall k, m$

Where Y_{mk} = the number of deposit items from customer group m processed by bank k

b_m = the total number of checks to be processed from customer group m

Reprinted from Summer 1976 issue of JOURNAL OF BANK RESEARCH, published by Bank Administration Institute.

q_{mk} = the dollar value of the mail float carried as accounts receivable balances that is generated when one check is mailed by customer group m to bank k

r_{mk} = the dollar value of the collection float that is generated when one check of customer group m is cleared through bank k

e_{mk} = the variable bank costs of processing one check from customer group m through a lock-box operated by bank k (if this cost does not differ for customer groups, then use e_k)

p = the opportunity cost of ledger balances

f_k^c = a fixed charge for using bank k as a collection point

Z_k^c = one if bank k is used as a lock-box site, zero otherwise

The constraint sets (2) and (4) together insure that all the checks will be allocated, while constraint set (3) insures that no checks will be sent to a "closed" lock-box.

In this model, a homogenous customer group is defined as a collection of customers whose combined mailing and clearing time to each potential lock-box site is the same. Although this does not require that customers be geographically contiguous, in practice customers are grouped by the first two or three digits of their ZIP codes.

The lock-box problem is equivalent to the simple warehouse location problem. Both problems have received extensive coverage in the O.R. literature (see, for example, [Drysdale and Sandiford, 1969], [Feldman, et. al., 1966], [Kraus, et. al., 1970], [Kuehn and Hamburger, 1963], [Shanker and Zoltners, 1972], and [Spielberg, 1969].) In fact, both of these formulations are part of a class of models referred to as the fixed charge location allocation problem by Ellwein [1970] and Ellwein and Gray [1971]. The name stems from the fact that the problem may be approached in two stages. First, one selects a subset of the possible bank location sites and second, one allocates the customers among those selected sites in a manner which minimizes the mail and collection float.

The first stage of the problem is combinatorial in nature, since the number of possible subsets of the location sites is $2^k - 1$ where k is the number of banks under consideration. The second stage of the problem can be solved in general as a transportation problem; however, for the lock-box problem this simplifies further because the bank collection activities are uncapacitated. This simplification permits a solution to be obtained for the second stage of the problem by assigning each customer group to the bank location that gives the minimum float. Because of the simple nature of the second stage, the algorithms that have been proposed are primarily concerned with finding an efficient method for searching the feasible subsets of location sites. Both branch and bound and implicit enumeration have been shown to be efficient and capable of finding the optimal solution to a reasonably sized versions of this problem in a matter of seconds. (See, [Bent, 1972], [Bulfin and Unger, 1973], [Ciochetto, et. al., 1972], [Davis and Ray, 1969], [Effroymson and Ray, 1966], [Khumawala, 1971 and 1972] and [Pogue, et. al., 1970].)

In this paper we will not be further concerned with the computational aspects of the lock-box problem. Instead, we will examine whether this model, which focuses only on the collection side of the cash management function, is in fact a useful planning tool. In a previous paper [1974], we focused our attention on the difficulties inherent in implementing this model because of the high cost of obtaining bank service price information. Now we will ask the more fundamental question: Can the cost of operating a lock-box system be considered independently of the other

cash management costs? With that as our goal, we proceed to review the models for the disbursement activity.

THE CORPORATE PAYMENT PROBLEM

Corporate cash managers can also often generate significant cash savings from a more efficient use of their disbursement system. This savings is achieved by locating the check disbursement activity at offices and banks with "slow" mail and clearing times, respectively. The problem of locating those disbursement activities which maximize the net benefits from the increased disbursement float was first discussed by Shanker and Zoltner [1972, Spring]. The formulation that follows is an extension of Shanker and Zoltner's work:

$$\text{(5)}\quad \text{MAX } W = \Sigma_i \Sigma_j \Sigma_k (p \cdot P_{ijk} - d_{jk}) X_{ijk} - \Sigma_k f_k^D \cdot Z_k^D - \Sigma_i f_i^R \cdot Z_i^R - \Sigma_i \Sigma_k f_{ik}^{DR} \cdot Z_{ik}^{DR}$$

$$\text{(6)}\quad \text{s.t. } \Sigma_i \Sigma_k X_{ijk} = a_j \qquad \forall j$$

$$\text{(7)}\quad \Sigma_i \Sigma_j X_{ijk} \leq (\Sigma_j a_j) Z_k^D \qquad \forall k$$

$$\text{(8)}\quad \Sigma_j \Sigma_k X_{ijk} \leq (\Sigma_j a_j) Z_i^R \qquad \forall i$$

$$\text{(9)}\quad \Sigma_j X_{ijk} \leq (\Sigma_j a_j) Z_{ik}^{DR} \qquad \forall i,k$$

$$\text{(10)}\quad X_{ijk} \geq 0;\ Z_k^D, Z_i^R, Z_{ik}^{DR} = 0 \text{ or } 1 \qquad \forall i,j,k$$

where X_{ijk} = the number of checks to be issued by regional office i to creditor group j on bank k

a_j = the total number of checks to be issued to creditor group j

P_{ijk} = the dollar value of the float generated by disbursing one check from regional office i to creditor group j on bank k

d_{jk} = the per item bank cost of processing one check for creditor group j through bank k (if this cost does not differ for creditor goups, then use d_k)

p = the opportunity cost of ledger balances

f_k^D = a fixed charge for disbursing at bank k

Z_k^D = one if bank k is used for disbursements, zero otherwise

f_i^R = a fixed cost to the firm for locating and maintaining a disbursement activity at regional office i

Z_i^R = one if a disbursement activity is located at regional office i, zero otherwise

f_{ik}^{DR} = a fixed cost to the firm for maintaining a relationship between regional office i and bank k

Z_{ik}^{DR} = one if a relationship is established between regional office i and bank k, zero otherwise

Here, the constraint set (6) is needed to insure that all of the checks that are owed to creditor group j are processed while the constraint sets (7), (8) and (9) are needed to insure that all activities occur through "open" offices and banks.

On first inspection, it may appear that this model is considerably more difficult to solve than that of the lock-box location problem. This is in fact not the case. The two-stage approach described in the

previous section can still be applied to this model with no serious increase in complexity. However, it would generally be true that the number of integer 0-1 variables would be considerably greater here than in the lock-box problem. Again, we must caution against overenthusiastic acceptance of the solution of this model, since it makes the very strong implicit assumption that the cost of operating the disbursement system is independent of other cash management costs.

A SYSTEMS APPROACH TO CASH MANAGEMENT

The two preceding models described in this paper are characterized by their failure to view the collection and disbursement activities in a framework which properly considers the interrelationships between them. Calman[1968] first proposed a comprehensive model of the firm's entire banking system. This model, which was later revised by Pogue et. al, [1970] provides a means of determining the true costs of the various components of the system. A limitation of their model is that it only determines activity levels within the firm's current banking system. As the two previous models indicate, firms often want to consider possible changes in the current banking structure. Therefore, in the next section we present a cash management model which unifies the two previous location models along the lines suggested by Calman and Pogue into a model capable of locating banking activities as well as determining their optimal levels.

A UNIFIED LOCATION MODEL

The key to a unified cash management model is the explicit determination of the optimal level of total bank compensation. In order to appreciate why this is so, one must understand the service pricing policy of commercial banks. Generally, commercial banks offer their services in a package for which they are partially compensated by a minimum balance requirement on a line of credit. When a compensating balance is required, the bank will often allow a service charge credit to be earned on the balance, which may be used to offset charges for other bank services. This policy often permits the firm to obtain double use of such funds. If a firm has already established its lines of credit, it may have a sizable pool of service charge credit that it can use to offset lock-box and disbursement charges. Therefore, unless all of the firm's banking activities are considered simultaneously, it is impossible to establish a basis for a cost analysis. It is this conclusion that makes the cost information required by the first two models impossible to obtain and leads us to the consideration of a unified approach.

In this model we will consider three separate ways of compensating a bank for its services. First, the bank can be paid in the form of cash fees FEE_k. Second, the bank can give a service charge credit C_k^N for each dollar of average net collected balances NCB_k on deposit. (The net collected balance is the true bank balance.) Finally, the bank can give a credit C_k^T for each dollar of tax payments TP_k the firm makes through the bank. (The reason the bank will allow credit is that there is often a substantial delay between the time the firm is required to pay its taxes and the time the U.S. Treasury actually withdraws funds.) We assume that the bank must be compensated for its total cost of processing disbursements TCD_k, its total cost of processing lock-box collections TCC_k and the value of any other tangible or intangible services V_k it performs for the firm. With

these assumptions, we can write the bank compensation constraint as:

$$(11)\quad FEE_k + C_k^T \cdot TP_k + C_k^N \cdot NCB_k \geq TCD_k + TCC_k + V_k$$

which must hold for each bank k under consideration in the system. Each of the variables in this equation is subject to additional constraints, which we now explore in some detail.

The tax payments the firm makes thru its bank is constrained by its total tax liability TPP. We express this as:

$$(12)\quad \Sigma_{k=1}^{K} TP_k \leq TTP$$

Because of its existing lines of credit, the firm must maintain a minimum level of net collection balances in each bank. Thus,

$$(13)\quad NCB \geq g_k,$$

where g_k is the required minimum balance.

Since an assumption of our model is that all parameters are known with certainty, the firm will generally find it optimal to allocate its cash balances to banks in such a way that equation (13) holds with equality. In practice, firms may desire to keep net collected balances above those required by its credit agreements because of the uncertainties associated with the timing of collections and disbursements and because of the desire to maintain access to bank loans in the event of an unforeseen credit need. These uncertainties can easily be incorporated into the model at this point through the introduction of chance constraints. Since an excellent discussion of these constraints in contained in Pogue, Faucett and Bussard [1970], however, we will proceed under our initial assumption.

In order to evaluate the benefits from a redesigned cash management system, we must find a relationship between the firm's average ledger-cash balance and the net collected balance on which the bank bases its computations. These two figures differ because of delays in the payment of checks written by the firm and the collection of checks received by the firm.

The delay in payments (positive float) is due to two factors: the mail delay between the firm's regional office i that issued the check and the location j of the vendor's receiving address; and the clearing time from the vendor's bank back to the firm's bank k upon which the check was drawn. (In addition to the mail and clearing float, there are generally various small delays such as the time the customer needs to process the check. For the purposes of this model, we assume these delays are independent of the issuing location and the bank on which the check was drawn.) If we let X_{ijk} denote the number of checks to be issued by regional office i to creditor group j on bank k, and let p_{ijk} denote the average dollar value of the float generated by disbursing one check for group j from regional office i through bank k, then $\Sigma_i \Sigma_j p_{ijk} X_{ijk}$ will represent the total amount of positive float associated with bank k.

Similarly, the delay in collections (negative float) has two contributions: The mail time from customer group m's location to a lockbox located at bank k; and the clearing time from bank k back to the customer's bank. The mail time, however, does not affect the relationship between the firm's average ledger cash balance and its net collected balances because both balances are computed after the mail time has elapsed. Using our previous definition of Y_{mk} as the number of deposit items processed from customer group m by bank k, and letting r_{mk} be the average dollar value of the collection float generated when one check of customer

group m is cleared through bank k, we can formulate the negative float associated with bank k as $\Sigma_m r_{mk} \cdot Y_{mk}$.

The relationship between NCB_k, the net collected balance, and BAL_k, the ledger balance, can now be expressed as:

$$(14) \quad NCB_k = BAL_k + \Sigma_{i=1}^{I} \Sigma_{j=1}^{J} P_{ijk} \cdot X_{ijk} - \Sigma_{m=1}^{M} r_{mk} \cdot Y_{mk}$$

which holds for all banks k under consideration.

Additional constraints are required to guarantee the assignment of all checks to one of the lock-box or disbursement account locations. These constraints were used in the previous models and are simply rewritten here as:

$$(6) \quad \Sigma_{i=1}^{I} \Sigma_{k=1}^{K} X_{ijk} = a_j \text{ for all creditor groups } j.$$

$$(2) \quad \Sigma_{k=1}^{K} Y_{mk} = b_m \text{ for all customer groups } m.$$

Returning now to the right hand side of the bank compensation constraint (11), we derive a formula that relates the disbursement activity levels X_{ijk} to the bank's total cost for operating the disbursement system TCD_k. We assume that the costs of operating the disbursement system can be divided into fixed and variable portions. If we let d_{jk} be the cost of processing one check from creditor group j through bank k, then the variable portion can be expressed as: $\Sigma_i \Sigma_j d_{jk} \cdot X_{ijk}$. The fixed costs, those costs that do not depend on the level of various activities, can be either attributed to the individual regional offices that use the account or to the bank's maintenance of that account. Therefore, in this model the treatment of the fixed charges f_k^C, f_k^D and F_{ik}^{DR} differs from that of the previous models. We have divided the fixed charges into the portion the bank incurs $\hat{f}_k^C$, $\hat{f}_k^D$, and $\hat{f}_{ik}^{DR}$ and therefore must receive compensation for, and the portion that the firm incurs $\bar{f}_k^C$, $\bar{f}_i^R$, $\bar{f}_{ik}^{DR}$ and must therefore be accounted for, but for which it does not have to compensate its banks.

With these assumptions, we can express TCD_k as:

$$(15) \quad TCD_k = \Sigma_{i=1}^{I} \Sigma_{j=1}^{J} d_{jk} \cdot X_{ijk} + \Sigma_{i=1}^{I} \hat{f}_{ik}^{DR} \cdot Z_{ik}^{DR} + \hat{f}_k^D \cdot Z_k^D$$

which holds for each bank k. The variables Z_{ik}^{DR} and Z_k^D are integer 0-1 variables that indicate the existence of a disbursement account at bank k (Z_k^D) or the existence of regional office-bank relationship (Z_{ik}^{DR}).

The analysis of the total cost of processing lock-box collections is similar. Letting e_{mk} be the cost of processing one customer check from customer group m at the lock-box located at bank k, we have as the variable portion of TCC_k: $\Sigma_m e_{mk} \cdot Y_{mk}$. If we let $\hat{f}_k^C$ be the fixed charge assesed by bank k for servicing the lock-box, then the total cost of collections can be written as:

$$(16) \quad TCC_k = \Sigma_{m=1}^{M} e_{mk} \cdot Y_{mk} + \hat{f}_k^C \cdot Z_k^C \text{ for each bank } k,$$

where Z_k^C is an integer 0-1 variable that indicates the existence of the lock-box at bank k.

A final set of constraints are need to control the values of the integer variables Z_k^D, Z_k^C, Z_i^R and Z_{ik}^{DR}. They are constraints (3), (7), (8) and (9) from the previous models:

(3) $\Sigma_{m=1}^{M} Y_{mk} \leq (\Sigma_{m=1}^{M} b_m) \cdot Z_k^C$

for all banks k.

(7) $\Sigma_{i=1}^{I} \Sigma_{k=1}^{K} X_{ijk} \leq (\Sigma_{j=1}^{J} a_j) \cdot Z_k^D$

for all banks k.

(8) $\Sigma_{j=1}^{J} \Sigma_{k=1}^{K} X_{ijk} \leq (\Sigma_{j=1}^{J} a_j) \cdot Z_i^R$

for all regional offices i.

(9) $\Sigma_{j=1}^{J} X_{ijk} \leq (\Sigma_{j=1}^{J} a_j) \cdot Z_{ik}^{DR}$

for all regional office i and bank k combinations.

The last part of the model to be specified is the objective function. We assume that the firm wishes to minimize the cost of its banking system. The cost of the system can be viewed as consisting of two portions. First, there is the direct out of pocket costs. These include the fees paid to the bank and the fixed costs of the various banking relationships:

$$\Sigma_{k=1}^{K} FEE_k + \Sigma_{k=1}^{K} [\overline{f}_k^C \cdot Z_k^C + \overline{f}_k^D \cdot Z_k^D + \Sigma_{i=1}^{I} \overline{f}_{ik}^{DR} \cdot Z_{ik}^{DR}] + \Sigma_{i=1}^{I} \overline{f}_i^R \cdot Z_i^R$$

where $\overline{f}_k^C$, $\overline{f}_k^D$, and $\overline{f}_{ik}^{DR}$ represents the fixed cost to the firm respectively of its collection, disbursement and regional office relationships. The cost $\overline{f}_i^R$ represents the fixed cost for locating and maintaining a disbursement activity at regional office i.

The second portion of the objective function evaluates the savings from decreased collection and increased disbursement times in the form of lower cash requirements to operate the banking system. More explicitly, we measure the change in the firm's ledger balance $\Sigma_k BAL_k$ and the reduction in receivables due to reduced mail collection times $\Sigma_m \Sigma_k q_{mk} \cdot Y_{mk}$. We evaluate these savings by using the opportunity cost p of the ledger balances. Combining these savings terms with the previous costs we have as our objective function the following:

(17) MINIMIZE $W = p(\Sigma_{k=1}^{K} BAL_k + \Sigma_{m=1}^{M} \Sigma_{k=1}^{K} q_{mk} \cdot Y_{mk}) + \Sigma_{k=1}^{K} FEE_k + \Sigma_{k=1}^{K} [\overline{f}_k^C \cdot Z_k^C + \overline{f}_k^D \cdot Z_k^D + \Sigma_{i=1}^{I} \overline{f}_{ik}^{DR} \cdot Z_{ik}^{DR}] + \Sigma_{i=1}^{I} \overline{f}_i^R \cdot Z_i^R$.

COMPUTATIONAL CONSIDERATIONS

The unified location model fits into the framework of the fixed charge location allocation formulation, and may therefore be solved by the two-stage procedure previously described. Two major considerations in the use of branch and bound or implicit enumeration as a solution technique should be mentioned. First, the second stage of the solution process can no longer be solved by a simple assignment of customers to the nearest bank location and vendors to the furthest bank location; rather one must solve a linear program to find the optimal choice of these assignments. Second, the number of integer 0-1 variables is potentially greater in this model than in either of the previous ones. Because of the sensitivity of integer programs to the number of integer variables involved, the user must be cautious when defining his set of bank and regional office locations. He should be especially cautious about the number of regional office-bank relationships he wishes to consider, since the number of integer variables is given by $I + 2K + IK$ where I is the number of regional offices and K is the number of banks. After careful consideration of reported computational experience, the authors believe that a problem containing 25 potential bank sites and three potential regional offices is within the range of available integer

programming codes. (See specifically [Ciocio, et. al., 1972], [Davis and Ray, 1969], [Ellwein, 1970], [Khumawala, 1971 and 1972] and [Spielberg, 1969].

POST OPTIMAL ANALYSIS

A solution to the dual problem of the proposed unified location model can provide additional information about the sensitivity of the model to changes in some of its parameters. For instance, the shadow price associated with constraint (13) can be used to measure the cost of an increase in a required compensating balance level. In addition, the shadow prices on constraints (2) and (6) can measure the impact of a shift in creditor or customer geographic distrubtion. Unfortunately, the integer nature of the model precludes using simple shadow price information to measure the cost of different office and banking relationships. However, this information could be obtained as a byproduct of the branch and bound or implicit enumeration algorithm chosen as a solution procedure.

CONCLUDING REMARKS

In this paper we were concerned with the question of whether the lockbox and disbursement portions of the cash management problem could be unified in one model. The need for this unification arises from the interrelationship between the costs of these two activities. Following Calman and Pogue, we found that the key to such a unification was the explicit consideration of the total level of bank compensation. The proposed model is designed to locate bank activities as well as to determine the optimal levels of these activities.

APPENDIX A

SUMMARY OF THE MODEL

Objective Function

$$(18)\quad \text{MINIMIZE } W = p\Big(\sum_{k=1}^{K} BAL_k + \sum_{M=1}^{M}\sum_{k=1}^{K} q_{mk} \cdot Y_{mk}\Big) + \sum_{k=1}^{K} FEE_k + \sum_{k=1}^{K}\Big[\overline{f}_k^C \cdot Z_k^C + \overline{f}_k^D \cdot Z_k^C + \sum_{i=1}^{I} \overline{f}_{ik}^{DR} \cdot Z_{ik}^{DR}\Big] + \sum_{i=1}^{I} \overline{f}_i^R \cdot Z_i^R$$

Constraints

All creditor checks must be processed:

$$(6)\quad \sum_{i=1}^{I}\sum_{k=1}^{K} X_{ijk} = a_j \qquad \forall_j$$

All customer deposits must be processed:

$$(2)\quad \sum_{k=1}^{K} Y_{mk} = b_m \qquad \forall_m$$

Definition of net collected balances:

$$(14)\quad NCB_k = BAL_k + \sum_{i=1}^{I}\sum_{j=1}^{J} P_{ijk} \cdot X_{ijk} - \sum_{m=1}^{M} r_{mk} \cdot Y_{mk} \qquad \forall_k$$

Net collected balances can support either compensating balances or supporting balances:

$$(13)\quad NCB_k \geq g_k \qquad \forall_k$$

Definition of TCD_k:

$$(15)\quad TCD_k = \sum_{i=1}^{I}\sum_{j=1}^{J} d_{jk} \cdot X_{ijk} + \hat{f}_k^D \cdot Z_k^D + \sum_{i=1}^{I} \hat{f}_{ik}^{DR} \cdot Z_{ik}^{DR} \qquad \forall_k$$

Definition of TCC_k:

$$(16)\quad TCC_k = \sum_{m=1}^{M} e_{mk} \cdot Y_{mk} + \hat{f}_k^C \cdot Z_k^C \qquad \forall_k$$

Bank compensation constraint:

$$(11)\quad FEE_k + c_k^T \cdot TP_k + c_k^N \cdot NCB_k \geq TCD_k + TCC_k + V_k \qquad \forall_k$$

TAW-R-COCDR1#80Attachment
Page 699 of 739

Constraints for integer variables Z_k^C:

$$(3)\quad \Sigma_{m=1}^{M} Y_{mk} \leq (\Sigma_{m=1}^{M} b_m) \cdot Z_k^C \qquad \forall_k$$

Constraints for integer variable Z_k^D:

$$(7)\quad \Sigma_{i=1}^{I} \Sigma_{j=1}^{J} X_{ijk} \leq (\Sigma_{j=1}^{J} a_j) \cdot Z_k^D \qquad \forall_k$$

Constraints for integer variable Z_i^R:

$$(8)\quad \Sigma_{j=1}^{J} \Sigma_{k=1}^{K} X_{ijk} \leq (\Sigma_{j=1}^{J} a_j) \cdot Z_i^R \qquad \forall_i$$

Constraint for integer variable Z_{ik}^{DR}:

$$(9)\quad \Sigma_{j=1}^{J} X_{ijk} \leq (\Sigma_{j=1}^{J} a_j) \cdot Z_{ik}^{DR} \qquad \forall_{i,k}$$

Constraint on available tax payments:

$$(12)\quad \Sigma_{k=1}^{K} TP_k \leq TTP$$

We assume the continuous variables, FEE_k, X_{ijk}, Y_{mk}, NCB_k, and TP_k are non-negative and BAL_k is unrestricted in sign. The integer variables Z_k^D, Z_k^C, Z_i^R, and Z_{ik}^{DR} are all restricted to be either 0 or 1.

Deregulation and Oligopolistic Price-Quality Rivalry

By JAMES H. VANDER WEIDE AND JULIE H. ZALKIND*

Domestic airlines, commercial banks, and motor trucking are oft-cited examples of industries in which price and the number of competitors are regulated, but firms compete freely on product quality. Other industries, such as commercial banks in limited-branching states, are more usefully thought of as being regulated on the quality dimension, but free to compete on price. Congress is considering several proposals to deregulate both types of industry. This paper presents a model of regulated, oligopolistic rivalry that can help evaluate congressional proposals for deregulation.

Deregulation of price-, quality-, and entry-regulated industries will be discussed in this paper within the framework of an explicit model of oligopolistic rivalry. The earlier work of Lawrence White, David Levhari and Yoram Peles, James Rosse, Elisha Pazner, and Rosse and John Panzar analyzed the effect of regulation on quality offerings in both monopolistic and perfectly competitive industries. These authors either said nothing directly about quality offerings in other industries, or indicated that oligopolistic results lie between those of monopoly and perfect competition. Panzar and Richard Schmalensee have shown that additional insight about the economic performance of oligopolistic markets such as airlines, banking, and trucking can be obtained from explicit models of oligopolistic behavior.

*Associate professor, Graduate School of Business Administration, Duke University, and director, Mid-term Analysis Division, Energy Information Administration, U. S. Department of Energy, respectively. We would like to thank our colleagues Wesley Magat and David Peterson for their helpful critiques of an earlier draft. We would also like to thank Richard Arnould for suggesting the applicability of this model to safety regulation and David Zalkind for suggesting the means of incorporating safety and the derivation of the results for $\partial x/\partial \bar{p}$ in the advertising case.

The present work differs from those of Panzar and Schmalensee in three important respects. First, we present a model of price variation in oligopolistic, *quality*-regulated markets such as commercial banking in limited-branching states, as well as a model of quality variation in price-regulated markets. Panzar and Schmalensee only consider models of the latter type.

Second, we extend the analysis of Panzar and Schmalensee to include situations of increasing or decreasing returns to scale in quality. Since Arthur DeVany finds evidence of increasing unit flight costs in the airline industry, and both George Benston and Frederick Bell and Neil Murphy find evidence of decreasing returns to scale in bank branches, we believe this extension significantly broadens the applicability of our results.

Finally, we explicitly analyze the economic effects of price, quality and/or entry deregulation of oligopolistic markets. Our analysis of deregulation is particularly relevant at a time when Congress is deregulating the airline, banking, and trucking industries, the CAB is allowing airline firms more freedom to lower fares and enter markets, and state legislatures are loosening restrictions on bank branches. The comparative static analyses of our predecessors do not address the economic effects of these changes directly.

The economic consequences of deregulation depend on a variety of factors, including the previously regulated variables, the choice of variables to deregulate, the appropriate type of individual firm cost and demand functions, and the relationship of the fixed values of the regulated variables to those which would obtain in an unregulated oligopoly. If entry into airline markets is deregulated, for instance, then the number of flights per carrier, the number of passengers per carrier and the load factor de-

TAW_R_COCDR1#80Attachment
Page 703 of 739

crease, but total flights serving the market and total passengers in the market increase. If both price and the number of competitors are deregulated, however, the increase in market flights resulting from entry deregulation may be more than offset by a decrease in market flights resulting from price deregulation. Regulators should be aware of these dependencies when choosing a deregulation policy.

I. The Model

The oligopolistic firm of our model produces a product with both quantity and quality dimensions. Although the firm's revenue is explicitly based only on the quantity sold, the demand for its product depends on its own price and quality, as well as its competitor's price and quality levels.

The meaning of the product quantity, quality, and price dimensions depends on the market context. Within the context of airline regulation, quantity is often measured by the number of passengers, quality is measured by either the level of amenities per passenger or the number of flights serving each market, and price is measured by the ticket fare. Within the context of bank regulation, quantity might be measured by the number of customers served, quality by either the number of bank branches or the amount of free services per customer, and price by the interest offered on deposits.

The ensuing analysis depends on three simplifying assumptions: the assumption that the n firms in the market face identical demand and cost conditions; the assumption that the demand and cost functions take special forms; and the Cournot-Nash behavioral assumption that each firm views its rival's decisions as fixed. These assumptions reflect the economic character of price-quality rivalry in many oligopolistic markets. (Evidence in support of this assertion is cited in Schmalensee, fn. 3.)[1] They also permit analytic tractibility. Except for our generalization of their demand and cost functions, the above assumptions are identical to those chosen by Panzar and Schmalensee.

Let x_i be the quantity of firm i's product, q_i be the quality of firm i's product, p_i its price, and n the number of firms in the industry. Then the demand function is

$$(1)\quad x_i = G^0(q_i; q_1, \ldots, q_{i-1}, q_{i+1}, \ldots, q_n; p_i; p_1, \ldots, p_{i-1}, p_{i+1}, \ldots, p_n)$$

The identical firms assumption implies that G^0 is invariant with respect to permutations of its second through nth arguments and also with respect to permutations of its $n+2nd$ through $2n$th arguments. Thus, G^0 is the same for each firm. We assume that G^0 is homogeneous of degree α, $0 \leqslant \alpha < 1$, in its first n arguments and that G^0 is homogeneous of degree $-\gamma$, $0 \leqslant \gamma < 1$ in its final n arguments. The terms α and $-\gamma$ are the elasticity of firm i's quantity with respect to a simultaneous proportional change in all the firms' quality and in all the firms' price levels, respectively.

In the unregulated case, firm i's objective is to select q_i and p_i to maximize its profits

$$(2)\quad \pi_i(q_1, \ldots, q_n, p_1, \ldots, p_n) = p_i x_i - C(q_i, x_i)$$

where $C(q_i, x_i)$ is the (identical) cost function faced by all firms in the industry.

Under the Cournot and identical firms assumptions, firms make identical decisions. Thus, firm i can view its rival's choices as identical and equal to $\hat{q}$, $\hat{p}$, and it can view its own demand function (1) as

$$(3)\quad x = G(q, \hat{q}, p, \hat{p}, n) = G^0(q; \hat{q}, \ldots, \hat{q}; p; \hat{p}, \ldots, \hat{p})$$

The function G is homogeneous of degree α in its first two arguments and of degree $-\gamma$ in its third and fourth arguments. Similarly, we can write the demand function as in (3) in the case where p or q is regulated.

The homogeneity of the demand function implies (as shown in the Appendix) that

[1] The evidence in Schmalensee only provides support for these assumptions in the quality rivalry case. The argument in favor of the Cournot-Nash behavioral assumption is less convincing when firms compete on price. However, the Cournot-Nash assumption permits analytical tractibility and the results are likely to be indicative of those in a more realistic, but less tractible, setting.

TAW_R_COCDR1#80Attachment
Page 704 of 739

there exists $g(n)$ such that

$$(4) \quad G(q,q,p,p,n)=q^{\alpha}p^{-\gamma}g(n)$$

Denote the partial derivative of $G(q,\hat{q},p,\hat{p},n)$ with respect to the first argument q as $G_1(q,\hat{q},p,\hat{p},n)$. Then when $\hat{q}=q$ and $\hat{p}=p$, there exists $k(n)$ such that

$$(5) \quad G_1(q,q,p,p,n)=q^{\alpha-1}p^{-\gamma}k(n)$$

Similarly, there exists $\rho(n)$ such that

$$(6) \quad G_3(q,q,p,p,n)=q^{\alpha}p^{-\gamma-1}\rho(n)$$

Economic considerations suggest that quantity demanded is positive, that demand for a firm's product decreases as additional firms enter the market, that a firm's demand increases as its quality increases and that a firm's demand decreases as its price increases. These considerations imply

$$(7) \quad g(n)>0,\ g'(n)<0,\ k(n)>0,$$

and

$$\rho(n)<0$$

The elasticities of demand with respect to changes in the firm's own price and quality decisions are

$$(8) \quad E(n)=-\frac{\partial x/\partial p}{x/p}=-\frac{G_3P}{G}=-\frac{\rho(n)}{g(n)}$$

$$(9) \quad B(n)=\frac{\partial x/\partial q}{x/q}=\frac{G_1q}{G}=\frac{k(n)}{g(n)}$$

respectively. Both $E(n)$ and $B(n)$ are positive under assumptions (7).

The following special case of demand function (1), which we call the *market share rivalry* demand function, sometimes provides additional insight

$$(10) \quad x_i=\frac{q_i^e}{\sum_{j=1}^{n}q_j^e}\left(\sum_{j=i}^{n}q_j\right)^{\alpha}\left[\frac{a}{p_i}-\frac{b(n-1)}{\sum_{j\neq i}p_j}\right]$$

where

$$1>\frac{b}{a}>\frac{\gamma+1}{2}$$

This demand function is a generalization, to permit price rivalry as well as quality rivalry, of the special market share scheduling rivalry demand function used by Joseph Yance, George Douglas and James Miller, and Schmalensee. In this demand function $(\Sigma q_j)^{\alpha}$ measures the effect of total market quality and the term $q_i^e/\Sigma q_j^e$ measures the effect of changes in firm i's market share of quality. Quantity is negatively related to the firm's own price and positively related to the average price charged by other firms. For this demand function, we show in the Appendix that

$$g(n)=n^{\alpha-1}(a-b)^{\gamma}$$

$$k(n)=n^{\alpha-2}(ne+\alpha-e)(a-b)^{\gamma}$$

$$\rho(n)=-n^{\alpha-1}\left(\gamma a(a-b)^{\gamma-1}\right)$$

Then $E'(n)=0$ and if $\alpha<1<e$, $B'(n)>0$ and $\rho'(n)<0$.[2]

The demand function (1) permits the study of different types of regulation, including price regulation, quality regulation, and entry regulation. For example, the government may regulate airline price and restrict entry, leaving the quality choice to the firm. In contrast, the government may regulate both bank entry and a quality variable such as the number of branches per bank, and the firm is free to set price.

We will use two different types of cost functions, depending on the interpretation of the quality variable. The first cost function is appropriate to situations, such as branch banking and airline flight schedules, where the costs of additional quality are independent of the number of customers served.[3] This cost function is[4]

$$(11) \quad C(x,q)=dx+cq^{\beta}$$

[2] Douglas and Miller show that $\alpha<1<e$ is characteristic of the airline industry.

[3] Throughout the remainder of our analysis, we assume that the quantity variable x also measures the number of customers served. We noted earlier that this is appropriate for both the airline and banking industries.

[4] Panzar and Schmalensee use the version of this cost function where $\beta=1$.

TAW_R_COCDR1#80Attachment
Page 705 of 739

where c, d and β are nonnegative. The variable β measures the economies of scale with respect to quality in this case.

The second type of cost function is appropriate to situations, such as automobile safety, where quality attaches to each unit of output. For this case, we use the cost function[5]

$$C(x,q)=axq^{\delta}+dx \tag{12}$$

where a, δ, and d are nonnegative. The variable d is the cost of providing the basic unit of output, such as an automobile, to each customer and aq^{δ} represents the per customer cost of providing the quality of service q. The variable δ measures economies of scale in quality for this second case.

Although it is possible to combine the two types of cost functions into a single, more general form, the issues become considerably more complex when this is done. We believe our results are indicative of results that would obtain in a more complex setting.

II. Deregulation of Price and Entry when Quality is Independent of Output

Firms often compete on the basis of product quality in industries where price is fixed by regulatory control. The basic model can be adapted to such situations simply by fixing price at some level, say $\bar{p}$. The objective in this case is to choose q to maximize

$$\pi(q)=\bar{p}.x-C(x,q) \tag{13}$$

If quality is independent of the number of customers served, we can rewrite equation (13) as

$$\pi(q)=(\bar{p}-d)G(q,\hat{q},\bar{p},\bar{p},n)-cq^{\beta}$$

Each firm maximizes $\pi(q)$ under the assumption that competitors' decisions are invariant with respect to changes in q. The initial first-order condition is

$$(\bar{p}-d)G_1(q,\hat{q},\bar{p},\bar{p},n)-c\beta q^{\beta-1}=0$$

Since all firms are identical, under the Cournot assumption, they will all produce the same quality, i.e., $\hat{q}=q$. In equilibrium then, we can use equation (5) to rewrite the first-order condition as[6]

$$(\bar{p}-d)\bar{p}^{-\gamma}k(n)-c\beta q^{\beta-\alpha}=0 \tag{14}$$

A typical firm's equilibrium reaction to a change in the regulated price p, and number of firms n, is found through implicit differentiation of (14). Table 1 displays the comparative static results developed in the Appendix. The variables of interest include quality q and quantity x per firm, market output of quantity nx, quality nq, quality per customer q/x, and firm profits π.

A. *Banking*

We can use results of Table 1 to evaluate some current congressional proposals to deregulate the commercial banking industry. (In our interpretation of these results, we let the quality variable q measure branches per bank, the quantity variable x measure the number of customers per bank, and the variable n measure the number of banks in the market.) Most proposals call for an increase in the number of competitors and removal of all restrictions on the interest rates banks pay on demand and time deposits. In the context of our model, we evaluate these proposals by considering the effects of 1) a decrease in price $\bar{p}$ (a decrease in price is equivalent to an increase in interest rates), 2) an increase in the number of competitors n, and 3) a simultaneous decrease in price and increase in the number of competitors.

The first line of Table 1 describes both the firm and industry response to a decrease in price, holding the number of firms fixed.

[5]Levhari and Peles treat a more general form of this cost function. White treats the case where $\delta=1$ and Pazner treats a more general version of this cost function but with $d=0$. None of these analyses, however, apply to oligopolistic industries.

[6]The solution to this equation exists, is unique among symmetric solutions and satisfies second-order and entry restrictions as long as $(p-d)>0$, $G_{11}<0$, and $\beta>1$. Second-order conditions may also be satisfied for some values of $\beta<1$.

TABLE 1—COMPARATIVE STATIC EFFECTS OF CHANGES IN THE REGULATED VARIABLES p AND n WHEN QUALITY IS INDEPENDENT OF OUTPUT

Regulated Variables	Endogenous Variables					
	q	x	nx	q/x	π	$Q=nq$
p	Pos	$\frac{\alpha}{\beta\gamma}-\frac{p-d}{p}$	$\frac{\partial x}{\partial p}$	Pos	Pos	Pos
n	$k'(n)$[b]	Neg	Pos	Pos[a]	Neg	Pos

Note: Definition of variables: p = output price; n = number of firms in industry; q = amount of quality, for example, branches or flights; x = quantity of output; π = profit; α = elasticity of firm i's quantity with respect to simultaneous proportional change in all the firms' quality levels; $-\gamma$ = elasticity of firm i's quantity with respect to simultaneous proportional change in all the firms' price levels.

[a] True for market share rivalry demand function.

[b] In the case of the market share rivalry demand function, $k'(n)$ is negative for large n.

Branches per bank q, and total branches in the market nq, both decrease. This result is consistent with the results for a competitive firm found by White; namely, that when firms in a regulated competitive industry cannot compete on price, they compete away their excess profits through the quality variable. Since $d\pi/d\bar{p}>0$ in the oligopoly case, however, firms do not decrease quality so much that they compete away profits entirely.

A surprising result of our analysis is that the sign of $\partial x/\partial\bar{p}$ is indeterminate. We believe that $\partial x/\partial\bar{p}<0$ in most cases. In some cases, however, a decrease in the regulated price causes the bank to decrease its branches so much that demand actually decreases. This phenomenon occurs when $\alpha/\beta\gamma>(\bar{p}-d)/\bar{p}>1$. In this case, the market reaction to matched price changes measured by α is significantly greater than the product of the market reaction to matched quality changes measured by γ and the measure of economies of scale, β. Total industry output changes in the same direction as firm output.

The second line of Table 1 shows the responses to a change in the number of competitors, holding the regulated price fixed. The assumption that the banks entering (or leaving) the market are identical to the banks already in the market is implicit in the derivation of these results. An increase in n leads to a decrease in output per bank, but an increase in total output and branches in the market. Individual bank profits decline.

Policymakers could decide, of course, to allow free entry at the same time that they deregulate price. The effect of a simultaneous change in $\bar{p}$ and n can be found through analysis of the total differential:

$$dz=\frac{\partial z}{\partial\bar{p}}d\bar{p}+\frac{\partial z}{\partial n}dn$$

where z represents the variable of interest. For example,

$$dq=\frac{\partial q}{\partial\bar{p}}d\bar{p}+\frac{\partial q}{\partial n}dn \tag{15}$$

measures the effect of deregulation on the individual firm's quality choice. We know from Table 1 that $\partial\pi/\partial\bar{p}>0$ and $\partial\pi/\partial n<0$. Since simultaneous deregulation of both price and entry leads to lower p and higher n, deregulation will cause a decrease in individual bank profits. The effect of deregulation on total branches and output is indeterminate without empirical estimation of the demand and cost parameters.

B. *Airlines*

Recent models of the airline industry (see, for example, Douglas and Miller, Schmalensee, and Panzar) have assumed that regulatory authorities fix fares and the number of competitors, but allow firms to compete on their flight schedules. Both Congress and the CAB have deregulated the domestic airline industry. Most observers agree that deregulation will produce a de-

TAW_R_COCDR1#80Attachment
Page 707 of 739

crease in price and/or an increase in the number of competitors. If this observation is correct, the remaining consequences of deregulation can be predicted from the results displayed in Table 1. For the purposes of this analysis, the quality variable q is the number of flights per firm, the quantity variable x is the number of customers served by each firm, and the variable n is the number of airline firms in the market.

If price alone is deregulated, then deregulation will lead to a lower fare, fewer total flights, and lower industry profits.[7] The load factor will increase as well. More customers will be served if price effects significantly dominate quality effects. The social benefit of such a change is ambiguous, since customers pay lower fares at the possible expense of a reduction in flights. In small markets in which the regulated price may be below the equilibrium unregulated fare, these effects are reversed.

An alternative deregulation policy is to allow free entry into a given airline market, but retain control over fares. Adoption of this alternative would lead to a decrease in the number of flights per carrier (in the case of the demand function (10)); a decrease in customers served per carrier but an increase in total customers served by the market. If the special demand function (10) applies, there will be a decrease in the load factor and firm profits, and an increase in total flights in the market.

Finally, a policy of total deregulation of the large airline market will cause a decrease in fares, a decrease in the number of flights per market, and a decrease in firm profits.[8]

What alternative should the deregulators adopt? The answer depends on the social welfare weights attached to each price-quantity-quality combination. By indicating the directions of the economic effects of deregulation, as well as the parameters which need measurement to estimate the magnitude of these economic effects, however, our analysis should help clarify the debate.

[7]Firms will earn lower profits after deregulation if they are earning a positive economic profit prior to deregulation. If firms are not making positive economic profits prior to deregulation, then deregulation leads to higher profits, as shown in the Appendix. Casual empiricism suggest that this may be the case on many airline routes currently being deregulated.

[8]See fn. 7.

III. Price and Entry Deregulation when Quality Depends on Output

We use the cost function (12) to study the effects of deregulation when the quality variable of interest is attached to each unit of output sold, as in the airline meals case studied by White. In this case, profits are

$$\pi(q)=(\bar{p}-aq^{\delta}-d)G(q,\hat{q},\bar{p},\bar{p},n)$$

The Cournot equilibrium first-order condition for profit maximization is[9]

$$(\bar{p}-d)\frac{B(n)}{[1+B(n)]}-aq^{\delta}=0$$

where $B(n)$, the elasticity of demand with respect to matched changes in quality, is nonnegative.

The interpretation of quality in this case differs from the interpretation in the earlier case. Since quality in this case is inextricably attached to each unit of output sold, the variable q now measures quality per unit, and total firm quality offerings is measured by qx; that is, by quality per unit times the number of units sold. Similarly, the variable nqx measures total market quality.

Table 2 shows a comparative static analysis of the firm's reaction to changes in the regulatory variables p and n. The differences in the meaning of the quality variable lead to a number of differences between these results and those applicable to the previous cost function. First, the reactions of the quantity variables x and nx to changes in price restrictions are negative, and the reactions of excess profits π are positive only when $\gamma>\alpha$ and $\gamma\geqslant 1$. The reaction of the firm's and the market's total output of quality qx and nqx to changes in price is only determinate and positive when there are economies of scale in quality, i.e., $\delta\leqslant 1$.

[9]The solution to this equation exists, is unique among symmetric solutions, and satisfies second-order and entry restrictions as long as $p-af^{\delta}-d>0$, $G_{11}<0$, and $\delta>0$. Second-order conditions may be satisfied if $\delta<1$.

TAW_R_COCDR1#80Attachment
Page 708 of 739

TABLE 2—COMPARATIVE STATIC EFFECTS OF CHANGES IN THE REGULATED VARIABLES p AND n WHEN QUALITY IS TIED TO OUTPUT

Regulated Variables	Endogenous Variables						
	q	x	nx	qx		π	
p	Pos	$\frac{\alpha}{\gamma\delta}-\frac{p}{p-d}$	$\frac{\partial x}{\partial p}$	$\frac{\alpha+1}{\delta}-\frac{p-d}{p}$	$\frac{\partial qx}{\partial p}$	Pos	
n	Pos[a]	$\frac{\alpha}{\delta}+\frac{g'}{g}\frac{B(1+B)}{B'}$	Pos[a]	$\frac{\alpha+1}{\delta}+\frac{g'}{g}\frac{B(1+B)}{B}$	Pos[a]	$\frac{\alpha}{\gamma}-1+\frac{g'}{g}\frac{B(1+B)}{B'}$	[b]

Note: See Table 1; q = amount of quality per unit of output, δ = measure of economies of scale in quality, B = elasticity of demand with respect to changes in the firms' own price decision, g = a function reflecting the impact of the number of firms n on the quantity demanded of firm i's product.

[a] See Table 1.

[b] Negative for $\alpha < \gamma$.

Finally, in this case $\partial\pi/\partial n$ could be positive if α is much greater than γ. If the further assumptions that $\delta = 1$ and $\gamma > \alpha$ are made, then Table 2 shows that price deregulation leads to more customers but fewer services per customer.

The market share rivalry demand function permits analysis of the effects of entry deregulation. As the number of firms in the market increase, services per customer and per market increase.

IV. Quality-Regulated Oligopolies: Branch Banking and Safety

Quality regulation characterizes some industries better than price regulation. Examples of these industries include banking in limited-branching states and safety-regulated industries such as automobiles. The economics of quality regulation can be analyzed within the context of our model by treating the firm's quality variable as fixed. Then, the firm's objective is to choose p to maximize

$$\pi(p) = p \cdot x - C(x, \bar{q}) \tag{16}$$

We use (16) with the appropriate cost function to analyze cases such as branching where quality is independent of the firm's output and cases, such as automobile safety, where quality and output are inextricably tied together.

A. *Branch Banking*

Many states limit the number of branches that may be operated by any one bank and/or restrict entry into banking markets. Our model permits analysis of the economic effects of branch and/or entry deregulation. We treat the number of branches as an advertising-type quality variable measuring "convenience" and assume that banks are free to compete on price.

If the cost of establishing a branch is independent of the number of customers served, then (16) can be written as

$$\pi(p) = (p-d)G(\bar{q}, \bar{q}, p, \hat{p}, n) - c\bar{q}^{\beta}$$

and the profit-maximizing values of p is one which satisfies the first-order condition:[10]

$$p = \frac{dE(n)}{E(n)-1}$$

a solution which only makes economic sense when $E(n) > 1$.

Table 3 presents comparative static results useful for evaluation of branch and entry deregulation. We assume that branches per firm q and the number of firms n are less than their equilibrium unregulated values. The first row of Table 3 indicates the effect of deregulating the number of branches per firm, holding the number of firms constant. The second row indicates the effect of allowing free entry, while continuing to regulate branches.

[10] A solution exists, is unique among symmetric solutions, and satisfies positive profit requirements for entry if $(p-d) > 0$ and $G_{33} < 0$.

TABLE 3—COMPARATIVE STATIC EFFECTS OF CHANGES IN THE REGULATED VARIABLES q AND n WHEN QUALITY COST IS INDEPENDENT OF OUTPUT

Regulated Variables	Endogenous Variables				
	p	x	nx	x/q	π
q	0	Pos	Pos	Neg	Indet[b]
n	0[a]	Neg[a]	Pos[a]	Neg[a]	Neg[a]

Note: See Table 1; q = the amount of quality, for example, the number of branches.
[a]See Table 1.
[b]Positive for $\beta < 1$.

TABLE 4—COMPARATIVE STATIC EFFECTS OF CHANGES IN THE LEVEL OF SAFETY WHEN SAFETY IS INDEPENDENT OF UNITS SOLD

Regulated Variables	Endogenous Variables				
	p	x	nx	q/x	π
q	0	0	0	Pos	Neg
n	0[a]	Neg[a]	0	Pos[a]	Neg[a]

Note: See Table 1; q = amount of safety when safety is independent of output.
[a]See Table 1.

TABLE 5—COMPARATIVE STATIC EFFECTS OF CHANGES IN THE LEVEL OF SAFETY WHEN SAFETY IS ATTACHED TO EACH UNIT SOLD

Regulated Variables	Endogenous Variables			
	p	x	nx	π
q'	Pos	Neg	Neg	Neg
n	Neg	Neg[a]	0[a]	Neg[a]

Note: See Table 1; q' = amount of safety when safety depends on output.
[a]See Table 1.

Deregulation of branching leads to an increase in both bank and industry output. Since the number of branches affects marginal revenue and marginal cost proportionately, however, deregulation has no effect on equilibrium price. Because consumers can receive both greater convenience and quantity at the same price, their welfare is improved by free branching. Consumer welfare always comes at the expense of the firm when there are diseconomies of scale ($\beta > 1$).

If the market share rivalry demand function applies, deregulation of entry leads to an increase in market output and no change in price. Thus, consumer welfare is improved by this form of deregulation as well. Since individual firm profits decline under free entry, improvements in consumer welfare come at the expense of the firm.

B. *Safety Regulation*

Safety regulation is a special case of quality regulation in which quality has little or no effect on demand. This phenomenon is especially apparent in the automobile industry where manufacturers frequently insist that safety has no effect on passenger demand for automobiles. It is also apparent in the airline industry where passengers do not possess the knowledge to select a carrier on the basis of safety.

There are two types of safety: one that attaches to each unit sold, as in automobile safety, and another which is independent of the number of customers, as in airline safety. Tables 4 and 5, derived under the assumption that $\alpha = 0$, show the comparative static effects of safety regulation for the cost functions corresponding to these two cases. The

TAW_R_COCDR1#80Attachment
Page 710 of 739

contrast is striking. Since increased safety standards have no effect on the firms' price and output decisions in the case where safety is independent of the number of customers served, consumer welfare is unambiguously improved, but firm profits decline. In the case where safety attaches to each unit sold, however, equilibrium market price increases and quantity decreases when safety standards are raised. Thus, consumers share the cost burden of higher safety with firms.

V. Conclusion

We have developed an explicit model showing the effects of deregulation of an oligopolistic industry. The oligopoly form of the model permits explicit analysis of entry as well as price and/or quality deregulation. Our model pertains to two interpretations of quality and also allows for nonconstant returns to scale in quality. The direction and magnitude of the effects of deregulation depends on which variables were previously regulated and which are deregulated. These effects were determined in many cases without resort to statistical estimation of model parameters. The results of this paper should aid in the evaluation of recent proposals to deregulate important sectors of the American economy.

Appendix

A: The Demand Function

LEMMA: *$G_1(q, \hat{q}, p, \hat{p}, n)$ is homogeneous of degree $\alpha-1$ in the first two arguments.*

PROOF:

Differentiating G, gives

(A1)

$$\frac{\partial G(\lambda q, \lambda \hat{q}, p, \hat{p}, n)}{\partial q} = \lambda G_1(\lambda q, \lambda \hat{q}, p, \hat{p}, n)$$

and by definition

(A2)

$$\frac{\partial G(\lambda q, \lambda \hat{q}, p, \hat{p}, n)}{\lambda q} = \frac{\partial \lambda^{\alpha} G(q, \hat{q}, p, \hat{p}, n)}{\partial q}$$

$$= \lambda^{\alpha} G_1(q, \hat{q}, p, \hat{p}, n)$$

Combining (A1) and (A2) gives

$$G_1(\lambda q, \lambda \hat{q}, p, \hat{p}, n) = \lambda^{\alpha-1} G_1(q, \hat{q}, p, \hat{p}, n)$$

LEMMA: *There exists $g(n)$ such that $G(q, q, p, p, n) = q^{\alpha} p^{-\gamma} g(n)$.*

PROOF:

$G(q, q, p, p, n) = q^{\alpha} p^{-\gamma}\ G(1, 1, 1, 1, n)$ from the assumed homogeneity. Let $g(n) = G(1, 1, 1, 1, n)$.

LEMMA: *For the market share rivalry demand function*

$$x_i = \frac{q_i^e}{\sum_{j=1}^{n} q_j^e} \left(\sum_{j=1}^{n} q_j \right)^{\alpha} \left[\frac{a}{p_i} - \frac{b(n-1)}{\sum_{j \neq i} p_j} \right]^{\gamma}$$

A. $g(n) = n^{\alpha-1}(a-b)^{\gamma}$
B. $k(n) = n^{\alpha-2}(ne+\alpha-e)(a-b)^{\gamma}$
C. $\rho(n) = -n^{\alpha-1}\gamma a(a-b)^{\gamma-1}$

PROOF:

A. Let $q_i = q$, $p_i = p$ for $i = 1, \ldots, n$. Then

$$x_i = \frac{q^e}{nq^e}(nq)^{\alpha}\left(\frac{a}{p} - \frac{b(n-1)}{(n-1)p} \right)^{\gamma}$$

$$= q^{\alpha} p^{-\gamma} n^{\alpha-1}(a-b)^{\gamma}$$

B. Differentiate x_i with respect to q_i to get

$$\frac{\partial x_i}{\partial q_i} = \left(\sum q_j^e\right)\left[eq_i^{e-1}\left(\sum q_j\right)^{\alpha} + \alpha\left(\sum q_j\right)^{\alpha-1} q_i^e \right]$$

$$- q_i^e\left(\sum q_j\right)\alpha e q_i^{e-1} + \left(\sum q_j^e\right)^2$$

$$x\left[\frac{a}{p_i} - \frac{b(n-1)}{\sum_{j \neq i} p_j} \right]^{\gamma}$$

Set $q_i = q$ and $p_i = p$ for $i = 1, \ldots, n$. Then

$$\frac{\partial x_i}{\partial q_i} = nq^e\left[eq^{e-1}(nq)^{\alpha} + \alpha(nq)^{\alpha-1} q^e \right]$$

$$- q^e(nq)^{\alpha} e q^{e-1} +$$

TAW_R_COCDR1#80Attachment
Page 711 of 739

$$+(nq^e)^2 x\left(\frac{a-b}{p}\right)^{\gamma}$$

$$=n^{\alpha-1}[en+\alpha-1]q^{\alpha-1}p^{-\gamma}(a-b)^{\gamma}$$

C. The proof of C is similar to the proof of B.

B: Comparative Statics

The comparative static results shown in Table 1 are derived in this Appendix. (The results in Tables 2–5 are derived in much the same way as those in Table 1; the interested reader may obtain these derivations from the authors.)

If p is regulated and the cost of quality is independent of output, then the firm's objective is to choose q to maximize

$$\text{(A3)}\quad \pi(q)=(\bar{p}-d)G(q,\hat{q},\bar{p},\bar{p},n)-cq^{\beta}$$

and the first-order condition is

$$(\bar{p}-d)G_1(q,\hat{q},\bar{p},\bar{p},n)-c\beta q^{\beta-1}=0$$

Substituting for G_1, setting $\hat{q}=q$ and rearranging yields

$$\text{(A4)}\quad (\bar{p}-d)\bar{p}^{-\gamma}k(n)-c\beta q^{\beta-\alpha}=0$$

To determine the effect of changes in the regulatory variable n, implicitly differentiate (A4) and substitute (A4) into the result to obtain

(A5)

$$\frac{\partial q}{\partial n}=\frac{(\bar{p}-d)\bar{p}^{-\gamma}k\,(n)}{c\beta(\beta-\alpha)q^{\beta-\alpha-1}}=\frac{q}{\beta-\alpha}\cdot\frac{k'(n)}{k(n)}$$

Equation (A4) is used in a similar manner to obtain

$$\text{(A6)}\quad \frac{\partial q}{\partial \bar{p}}=\frac{k(n)\bar{p}^{-\gamma-1}[\,\bar{p}(1-\gamma)+d\gamma]}{c\beta(\beta-\alpha)q^{\beta-\alpha-1}}$$

$$=\frac{q}{\bar{p}}\cdot\frac{[\,\bar{p}(1-\gamma)+d\gamma]}{(\bar{p}-d)(\beta-\alpha)}$$

If profits are positive, then $\bar{p}>d$. Under the assumptions that $\beta>\alpha$ and $k'(n)<0$ (true in the special case) we then have $\partial q/\partial n<0$. Furthermore, since $\gamma<1$, when $\beta>\alpha$, $\partial q/\partial\bar{p}>0$. In equilibrium and from (A4)

$$\text{(A7)}\quad x=q^{\alpha}\bar{p}^{-\gamma}g(n)$$

$$=\left[\frac{(\bar{p}-d)k(n)\bar{p}^{-\gamma}}{c\beta}\right]^{\frac{\alpha}{\beta-\alpha}}\bar{p}^{-\gamma}g(n)$$

Differentiating $\ln x$ from (7) with respect to $\bar{p}$ we find that

$$\text{(A8)}\quad \operatorname{sgn}\frac{\partial x}{\partial\bar{p}}=\operatorname{sgn}\left(\frac{\alpha}{\beta\gamma}-\frac{\bar{p}-d}{\bar{p}}\right)$$

Differentiating (A7) with respect to n yields

$$\text{(A9)}\quad \frac{\partial x}{\partial n}=q^{\alpha-1}\bar{p}^{-\gamma}\left[\alpha g(n)\frac{\partial q}{\partial n}+qg'(n)\right]$$

We know that $\partial q/\partial n<0$, as derived above, and from the assumption that $g'(n)<0$ that $\partial q/\partial n<0$.

Let $Q=nq$ be total quality produced by the market. Then

$$\frac{\partial Q}{\partial\bar{p}}=n\frac{\partial q}{\partial\bar{p}}>0$$

and

$$\frac{\partial Q}{\partial n}=n\frac{\partial q}{\partial\bar{p}}+q\gtrless 0$$

Let $X=nx$ be market output. Then

$$\frac{\partial X}{\partial n}=n\frac{\partial q}{\partial n}+q\gtrless 0$$

Let $x/q=q^{\alpha-1}\bar{p}^{-\gamma}g(n)$ be customers per unit of quality. Then using (A6)

$$\frac{\partial(x/q)}{\partial\bar{p}}=q^{\alpha-2}\bar{p}^{-\gamma-1}g(n)$$

$$\left[(\alpha-1)\bar{p}\frac{\partial q}{\partial\bar{p}}-\gamma q\right]<0$$

and

$$\frac{\partial(x/q)}{\partial n}=q^{\alpha-2}\bar{p}^{-\gamma}$$

$$\left[(\alpha-1)g(n)\frac{\partial q}{\partial n}+qg'(n)\right]\gtrless 0$$

Therefore $\dfrac{\partial q/x}{\partial\bar{p}}>0$.

TAW_R_COCDR1#80Attachment
Page 712 of 739

Equilibrium profits are found by substituting the cost function into (A3), and using (A4) and the definition of $B(n)$:

$$\text{(A10)} \quad \pi=(\bar{p}-d)\bar{p}^{-\gamma}q^{\alpha}g(n)-cq^{\beta}$$

$$=cq^{\beta}\left[\frac{\beta}{B(n)}-1\right]$$

When economic profits are positive, $\beta/B(n)>1$. Then, differentiating (A10) with respect to $\bar{p}$ and using (A6) we obtain

$$\frac{\partial\pi}{\partial\bar{p}}=c\beta q^{\beta-1}\left(\frac{\beta}{B(n)}-1\right)\frac{\partial q}{\partial\bar{p}}$$

which is positive when economic profits are positive. Differentiating (A9) with respect to n yields

$$\frac{\partial\pi}{\partial n}=c\beta q^{\beta-1}\left[\left(\frac{\beta}{B(n)}-1\right)\frac{\partial q}{\partial n}-\frac{qB'(n)}{B(n)^2}\right]$$

Since $(\beta/B(n)-1)>0$, $\partial q/\partial n<0$ and $B(n)>0$, then $\partial\pi/\partial n<0$, if $B'(n)>0$, which is true for the special case of our demand function.

Issues in Cash Flow Management

A Short–Term Disbursement Forecasting Model

Steven F. Maier, David W. Robinson, and James H. Vander Weide

Steven F. Maier and James H. Vander Weide are both Associate Professors at the Graduate School of Business Administration at Duke University. Their co-author, David W. Robinson, is Vice President of University Analytics in Durham, North Carolina.
This research was supported by grants from First Union National Bank and Girard Bank and Trust.

Introduction

Cash forecasting plays a critical role in the development of the firm's short-run financial plans. In times of stress, the cash forecast alerts the manager to pending financial problems, allowing him time to solve these problems before they become serious. In more normal periods, the forecast helps the manager determine the size and maturity of his short-term asset and borrowing portfolios. It also helps him to minimize idle cash balances.

Because the forecasting goals of firms differ significantly, a great variety of forecasting methods has been developed. Many firms feel most comfortable with deterministic forecasting methods that rely on the structure provided by the firm's financial statements. Examples are the cash budget and the *pro forma* balance sheets and income statements. These methods are based on a sales forecast together with assumptions concerning inventory and receivable policy, work force levels and changes in plant capacity. Computerized versions of these methods are described in Francis and Rowell [2], Scott, *et al.* [5], Stone [6], and Warren and Shelton [10].

Two recent papers by Stone and Miller [8] and Stone and Wood [9] describe an alternative, statistically-based approach to cash forecasting that was especially designed to forecast the firm's daily cash position. This approach uses a dummy-variable regression equation to estimate the typical pattern of cash flows over the days of the week and the days of the month. The resulting pattern is then used to "distribute" the firm's monthly cash budget to the days within the month. Stone and Wood use an additive form of the distribution model, while Stone and Miller use a multiplicative and mixed-effect form. The multiplicative form of the model provides better results for the case where the monthly cycle is large relative to a weekly

TAW_R_COCDR1#80Attachment
Page 715 of 739

pattern. A similar approach was used by Boyd and Mabert [1] to forecast daily check volume at Chemical Bank of New York.

The payments pattern method represents yet a third approach to cash forecasting. This approach relates components of the cash stream, such as cash collections, back to the source that generates them, *e.g.*, customer bills. It then estimates the distribution of the time delay between the mailing of the bill and the receipt of payment. For example, if the firm estimates that 80% of a given month's sales are collected in one month and 20% the following month, then the forecast of cash collections for this month is the sum of 80% of last month's sales and 20% of the sales made two months ago. As described in Lewellen and Edmister [3], Lewellen and Johnson [4], and Stone [7], the payments pattern approach is usually applied to the preparation of monthly cash forecasts, but there is no reason why it cannot be applied to daily cash forecasting as well.

This paper describes a statistical model of the firm's daily disbursements that follows the logic of the payments pattern approach to cash forecasting. The model generates daily cash forecasts from the mailing date and dollar amount of disbursements that are made, or that are scheduled to be made, during a time horizon not expected to exceed 90 days. Using the historical distribution of time between mailing date and clearing date, the model predicts when each disbursement item will affect the demand deposit account on which it is written.

In addition to its use of a payments pattern methodology, the model described here has three distinct features. First, it dynamically revises its cash forecast for future periods as previously written checks are paid. Second, it tracks and updates the distribution of check processing times for the firm's largest vendors as new information becomes available. Third, it can produce reports that alert the manager to significant changes in a particular vendor's check processing time, caused perhaps by a change in his lock box site.

Because the model addresses a very short-term forecasting problem, it may be useful for only some companies. In particular, the model should prove primarily useful for companies that cannot avail themselves of "controlled disbursing" or "managing around a target" methods. In controlled disbursing, a company uses a bank that can report actual check clearings on the same day they are presented. This allows the company to keep no idle balances in the bank and simply to transfer funds as needed, obviating the need for a disbursement forecast. Unfortunately, not all banks can provide this service. For example, because of the way checks are cleared, California and Chicago banks cannot offer controlled disbursing.

Another alternative to forecasting arises when a company has bank balances related to its financial activity or when it uses balances to compensate its bank for providing credit. In this case, the daily uncertainty in cash requirements associated with disbursing activity would be unimportant, because all that is of concern is that (on average) a target level of balances be achieved.

In summary, the model presented in this paper will prove most useful for companies that choose not to use controlled disbursing banks and whose required cash balances are insufficient to sustain the uncertainty associated with check clearings. Of course, many firms who do not need or require a good one- or two-day forecast could still benefit from forecasts of up to 30 days in order to better manage their investment and/or borrowing requirements.

The Disbursement Float Forecasting Model

The Disbursement Float Forecasting Model generates disbursement cash flow forecasts for individual large vendors and for the remaining vendors as a whole. Large vendor forecasts are based on a history of clearing times for each vendor. This history includes the minimum pay time, the expected time, and the variance. The aggregate check class uses the history for the weekday on which the checks were mailed as determined by observations obtained from the large vendor history file. Thus, checks mailed (or written) on Monday would have a different history of clearing times from those mailed on, say, Thursday.

The forecast of disbursements for a given day is prepared on a check-by-check basis for individual vendor checks and on a group basis for the aggregate class of checks. The expected dollars to be disbursed on or before the forecast day is found by multiplying the check amount by the estimated probability that the check will clear. For example, if there is a 75% chance that a $1,000 check will clear by June 5, the single check forecast amount would be $750. The estimated probabilities will increase with the forecast date, *i.e.*, as the check becomes older. Thus, the forecast for June 6 might be $830 (83% chance of clearing) and $900 for June 7.

There is often considerable variation in the length of time it takes for a particular check to clear. For this

TAW_R_COCDR1#80Attachment
Page 716 of 739

reason, the model generates both an expected value projection and a more conservative forecast.

The individual check values for each forecast day are added together to produce a single disbursement estimate. The aggregate group of checks gives rise to the same quantities (expected payments and variances), and these too are summed into the forecast. The variance figures allow the model to obtain the conservative estimates by increasing each day's expected cumulative disbursement amount by an appropriate safety factor.

The method works well when good estimates of the required probabilities can be obtained. Because check clearing times change periodically (for example, when a vendor opens a new lock box, or an existing mail route is changed), the probability estimates must be adjusted from time to time. The update method used insures that the system will "learn" the payment patterns for the company's checks as data are observed.

The distinction between the individual vendor and aggregate check classifications is important for the proper functioning of the model. Data on individual vendor clearings are used in the model in four ways:

1. To prepare forecasts of disbursements for all items in the individual vendor classification. These items are more predictable than those in the aggregate check classification because the clearing patterns of large vendors tend to be relatively stable (aside from major changes noted in 2 below).
2. To discover major changes in vendor clearing times caused, for example, by a change in the vendor's lock box system.
3. To update disbursement predictions for particular days in the future. If a certain check were expected to clear in five days and it actually clears in three, then the forecast for the fifth day should be adjusted downward for this new information. Adjustments of this kind are straightforward for items in the individual vendor classification.
4. To provide a history of average clearing times for each day of the week on which checks are mailed. Aggregate check forecasts are based on these average weekday times for individual vendors. (For the aggregate classification, it is not possible to associate the clearing date with the original mail date for each item; thus one cannot measure the aggregate average directly.)

The aggregate check classification is useful because it can considerably reduce the model's input requirements. Only one entry need be made for each day for the aggregate classification, as opposed to one for each check issued in the vendor classification. By using the individual vendor classification for large vendors and the aggregate check classification for the remaining vendors, the user obtains a reasonable tradeoff between desired accuracy and the cost of data input.

Probability Estimates

The probability that a given check (or group of checks) will clear on or before a given date depends on a number of significant factors:

1. The day of the week on which the check was mailed. (This turns out to be the most statistically significant effect because of the influence of weekend delays on mail, processing, and clearing times.)
2. The distance of the vendor from the check mail point.
3. Whether the vendor uses a lock box or has slower internal processing methods.
4. The location of the vendor's deposit bank and the extent to which it uses accelerated check clearing methods.
5. The amount of the check. (Large checks are often given priority treatment by vendors and banks. This occurs because large checks are generally routed to lock boxes, and many banks send such large items directly to expedite the clearing process.)
6. Environmental factors. (For example, mail is notoriously slow during the Christmas season and may be delayed at other times by such factors as strikes and weather.)

Rather than consider each of the above effects separately, the model summarizes the clearing history in terms of three statistics for each vendor and for each weekday on which the checks in the aggregate class are mailed. The three statistics computed for each check group are:

1. The expected time for a check to clear (in days).
2. The minimum time for a check to clear (in days). This is the smallest observed time.
3. The standard deviation of the time for a check to clear. This is computed as usual, *i.e.*, if n checks have been observed and the ith check cleared in d_i days, the standard deviation would be

$$SD = \sqrt{\frac{1}{n}\left[\sum_{i=1}^{n} d_i^2 - \frac{1}{n}\left(\sum_{i=1}^{n} d_i\right)^2\right]}. \qquad (1)$$

TAW_R_COCDR1#80Attachment
Page 717 of 739

The probability distribution of the number of days for an item to clear is the key variable in the model. A fairly large sample of these times was analyzed on a vendor-by-vendor basis, and the following conclusions were reached:

1. There is a characteristic minimum clearing time for each vendor; this varied from 1 to 10 days in our sample.
2. Once the data are transformed by subtracting the observed minimum time, the remaining values show a variety of distributions. A good characterization of such positive random variables is the coefficient of variation:

$$CV = \frac{\text{standard deviation}}{\text{mean}}.$$

   Coefficients of variation between 0.5 and 4.5 were observed.
3. A generally good fit to the observed distribution was obtained by selecting a discrete probability distribution based on the coefficient of variation:
   a. A binomial distribution when $CV \leq 0.95$.
   b. A Poisson distribution when $0.95 < CV < 1.05$.
   c. A negative binomial (or Polya) distribution when $CV \geq 1.05$.
   The parameters for each of the three distributions were selected so that they matched the observed times in both mean and standard deviation. Unfortunately, there were not sufficient data for any vendor to apply chi-square or other tests. The distributions do have the advantage of being easy to compute with well-understood properties.

Using the above conclusions, the model selects one of the three distributions for each vendor based on the vendor history parameters. As our development has been largely *ad hoc,* the justification for our method lies in its ability to produce good forecasts.

Forecast Production

The Disbursement Float Forecasting Model uses the vendor probability distributions to produce forecasts of expected *cumulative* payments. This forecast amount is determined by the following formula:

$$F_t = \sum_{i=1}^{n} A_i P_{it},$$

where

F_t = the cumulative amount predicted to clear by day t;

A_i = the amount of the ith check (the aggregate group of checks may be thought of as a single check for the purpose of this explanation);

P_{it} = the probability that check i clears on *or before* day t (computed using the probability distribution and parameters as determined by observation of previous check clearing times as discussed in the last section. As explained previously, the aggregate classification is based on observations for the individually tracked vendors.); and

n = the total number of outstanding checks.

The predicted amount to clear on a given day is computed from

$$f_t = F_t - F_{t-1};$$

i.e., it is the difference between two successive cumulative amounts.

The conservative forecast amounts are computed using the estimated standard deviation of F_t. This value is found from

$$SD = \left[\sum_{i=1}^{n} A_i^2 P_{it}(1-P_{it}) \right]^{1/2},$$

i.e., the square root of the sum of variances of the individual check clearing times. It should be noted that this formula assumes that the probability distributions for individual checks are independent. The authors have found this assumption to be reasonably accurate, especially when weekend effects are accounted for. (Companies must still be aware that certain phenomena such as unusual weather could cause this assumption to be violated.)

If n (the number of outstanding checks) is large, F_t will have an approximately normal distribution, and a β% confidence limit on the daily amount cleared is:

$$C_t = F_t + Z_\beta SD_t,$$

where Z_β is the β% point of the standard normal dis-

TAW_R_COCDR1#80Attachment
Page 718 of 739

tribution and C_t is the value of F_t that will be exceeded only β% of the time. (For example, $Z_{95} = .645$ is the default confidence level in the model.)

The conservative forecast amounts are modified somewhat to insure consistency. Thus, C_t will never be larger than the total amount of the outstanding checks on day t and it will be adjusted if necessary so that $C_t \leq C_{t+1}$. The conservative daily clearings c_t are determined in the same way as f_t, *i.e.*,

$$c_t = C_t - C_{t-1}.$$

Note that c_t may well be less than f_t in some cases, but the conservative cumulative disbursement forecast will always be higher than the expected forecast.

Parameter Updating

Each time an individual vendor check is paid, the parameters for the vendor and the mail day corresponding to this check in the aggregate class are updated. The minimum number of days is changed to a new lower value if the observed clearing time is below the previous minimum, and the sample variance is revised using Equation (1). The expected clearing time is treated somewhat differently.

To understand the treatment of expected values, consider the situation where one of the company's vendors opens a new lock box in the company's city. Mail, clearing, and processing times are likely to decrease substantially, which must be rapidly detected and allowed for in the forecast. This would not occur if the overall average clearing time were used in the forecast as the expected clearing time. For example, if 40 checks had been previously written by the vendor with an average clearing time of 7 days, and the new clearing time were 4 days, about 200 more checks would have to be observed at this level before the expected clearing time for the forecast would be equal to 4.5 days.

The expected clearing time is therefore updated using exponential smoothing. In this technique, the most recent observed clearing time and the previous expected time are used to create a new expected time using the following formula:

New Expected Time = $(1 - \alpha) \cdot$ Previous Expected Time + $\alpha \cdot$ Observed Time.

In the formula, the parameter α is the smoothing weight; its value is between 0 and 1. When α is small, little weight is given to the new observation, and the model tends to retain the existing expectation. When α becomes larger, the model's values change more rapidly.

Updating Aggregated Checks

Because checks assigned to aggregate check groups are not individually recorded, they cannot be deducted from the proper day's outstanding total when they are paid. For this reason, an approximate method is used to keep these totals up to date.

Suppose that the total amount of outstanding checks written on day t is T_t for t = 1, . . .,m. The probability that a check written on day t is paid on or before the current date is calculated using observations of previous check clearing times and the proper weekday history for day t; suppose that these probabilities are P_t, t = 1, . . .,m. (Note that this set of probabilities need not necessarily sum to 1, because each value is separately calculated from the different distributions for the days of the week.) The amount of money, E, which the model expects to clear on the current day is thus:

$$E = \sum_{t=1}^{m} P_t T_t.$$

As the paid check file is processed, the Disbursement Float Forecasting Model keeps track of the aggregate checks and it computes the total amount that has cleared. Suppose this amount is X. Then there are three cases to consider:

1. X is exactly equal to E. In this case, the outstanding total for each day is reduced by the expected amount paid, *i.e.*, P_tT_t is subtracted from T_t for t = 1,. . .,m.
2. X is less than E. The same kind of adjustment is made here as in case 1 except that the amount to be subtracted is multiplied by X/E so that the total deduction is equal to X. Thus, T_t is reduced by XP_tT_t/E for t = 1,. . .,m.
3. X is greater than E. Here we wish to subtract an amount greater than the expected payment from T_t, but the deduction cannot reduce the total below zero. Thus, it is decreased to:

   $$\text{Maximum } (T_t - XP_tT_t/E, 0)$$

   and the total amount subtracted is computed. If this amount is less than X, the entire process is repeated using the revised amounts T_t and a new value for X corresponding to the unallocated remainder of X.

Page 719 of 739

The Impact of Weekends

The impact of weekends on the model's ability to predict cumulative cash disbursements on day t can be explained in terms of the difference between two types of forecasting error: systematic error that affects all or almost all checks in a similar way, and non-systematic error that is unique to specific checks. Since the cash flow forecast is almost always the result of the sum of the predictions for a very large number of checks, the impact of non-systematic error is reduced by the prediction process itself. Further reduction in forecast error is thus most likely to occur only through the identification of systematic effects. Weekends are such an effect.

For the purpose of disbursement float forecasting, two weekend effects must be examined. The first occurs when a mailed check arrives at the vendor's office. If the office is closed on the weekend, the check must wait until Monday to be processed. The second effect occurs when a check completes the Federal Reserve clearing process. A check that normally would take three business days to be cleared may become available for presentation to the drawee bank on the weekend, when the bank is closed, causing the actual clearing time to be four or five calendar days.

We examined the impact of the first weekend effect by comparing a weekend-adjusted and an unadjusted forecast. The first was computed using the sum of surveyed business day mail times, an adjustment for checks arriving on weekends, and surveyed calendar day clearing times. This was compared to a forecast based on the sum of calendar day mail and clearing times. The results of our analysis showed no appreciable difference in the two approaches. (Our mail time and clearing time data were supplied by Phoenix-Hecht, Inc., a Chicago-based consulting firm that provides such data to the banking industry.)

This result could be explained at least for the large vendors by the efficiency of their bank lock box processing. The reason is that many but not all banks remain open throughout the weekend for receipt of items; some even initiate collection by depositing the checks with the Federal Reserve on Saturday.

The lack of an impact because of the first weekend effect has a very important side benefit. It turns out that, if we are not trying to detect the weekend effect described above, there is no need to isolate the mail time and clearing time from the total disbursement time. This means that the corporation that uses the model will not need to have access to externally surveyed mail and clearing time data.

The impact of the second weekend effect was examined by comparing 1) a prediction based on the number of working days, adjusting if the check would have been presented for payment on a weekend, with 2) a simple calendar day estimate of disbursement time. Our comparison was based on the standard deviation of the disbursement time error computed as follows:

$$\text{Standard Deviation of Disbursement Time Error} = \frac{\sqrt{\sum_{i=1}^{N} X_i^2 (A_i - D_i)^2}}{\sum_{i=1}^{N} X_i} \qquad (2)$$

where

X_i = dollar value of the ith check,
A_i = actual (observed) disbursement time for the ith check,
D_i = predicted disbursement time for the ith check in working days or calendar days, and
N = number of checks during the sample period.

In Exhibit 1, the first column is computed using a calendar-day forecast, while the second column uses a business-day forecast adjusted for a weekend if it occurs on the day of check presentation. The exhibit also contains information on the use of the exponential

Exhibit 1. Standard Deviations of Predicted Disbursement Times (in days) for both Calendar and Working Day Forecasts

Statistical Estimation Method	Calendar Day Forecast	Working Day Forecast (adjusted for weekends)
Exponential Smoothing		
$\alpha = 0.0$	1.89	1.88
$\alpha = 0.1$	1.93	1.69
$\alpha = 0.2$	1.90	1.69
$\alpha = 0.3$	1.78	1.72
$\alpha = 0.4$	1.79	1.80
$\alpha = 0.5$	2.06	1.90
$\alpha = 0.6$	2.02	2.00
$\alpha = 0.7$	1.89	2.10
$\alpha = 0.8$	2.02	2.18
$\alpha = 0.9$	2.23	2.26
$\alpha = 1.0$	2.14	2.36

Note: Based on the largest 55 vendors who account for approximately 75% of the disbursement dollars.

TAW_R_COCDR1#80Attachment
Page 720 of 739

smoothing method of updating a check's expected clearing time.

It is interesting to note that it is really the combination of the weekend correction and the use of the exponential smoothing method that is most effective. If one did not try to apply a statistical updating method (corresponding to the $\alpha = 0$ row of the exhibit), then the change due to a weekend correction is insignificant (a reduction in standard deviation from 1.89 to 1.88). Yet the reduction for the best exponential smoothing model was from 1.78 to 1.69. Moreover, the weekend correction projection also shows a lower sensitivity to a change in the optimal α value, which is a desirable property from the standpoint of statistical estimation.

In conclusion, our results would indicate that a correction for weekend effects is worthwhile for a weekend that occurs at the time of check presentation at the drawee bank, but not for a weekend that occurs at the time of receipt by the vendor.

Statistical Test

The Disbursement Float Forecasting Model was tested on disbursement data supplied by First Union National Bank for one of its corporate clients. It covered the three-month period, January–March 1977. The first two months were used to estimate the statistical distributions and the third month to test the model. The data showed an average of $8,200,000 disbursed per month. The average dollar-weighted days the checks were outstanding were 6.4 days, and the average check size was $2,300. The data also showed that the checks were being disbursed unevenly throughout the week. For the March data, the disbursement percentages over the period Monday through Friday were 16%, 8%, 16%, 22%, and 38%, respectively.

In trying to determine whether the model offers useful forecasting capabilities, it is important to consider the influence of the length of time being forecasted. In this study, we examined a simple one-day forecast and a longer range one-month forecast. A one-day forecast is of special importance to corporations without access to controlled disbursing accounts, since without this information a company will need to maintain large bank balances to cover check clearings instead of investing the funds. The need for a longer-term forecast is to provide better control over the investment and borrowing strategy of the firm. We limited our long-range forecast to one month because of data limitations.

Exhibit 2 shows the actual dollars paid and the actual number of dollars outstanding in checks that have been mailed as of each day in the sample period. We think the most useful statistic in this exhibit is the ratio of dollars paid to dollars outstanding expressed as a percent. For our test data, this ranged from a low of 6.1% to a high of 39.4%. On average, 24% of the total dollars outstanding was paid on the next business day. (The standard deviation expressed as a percentage of the total dollars outstanding was 10.5.)

Exhibits 3 and 4 present data on the accuracy of our expected and conservative one-month forecasts. The fourth column in Exhibit 3 shows the difference between the expected forecast and the actual amount paid on a cumulative basis. The fourth column in Exhibit 4 shows the difference between the conservative forecast and the actual amount paid. Column five in each exhibit expresses these two amounts as percentages of the dollars outstanding on each date.

Notice the following characteristics. First, the expected forecast in Exhibit 3 shows 10 instances in which the forecast was greater than the actual amount cumulative to that day and 13 times when the forecast was less than the actual amount. Using this measure (and others), we are able to confirm that our expected forecasts are in fact unbiased statistical estimates of the cumulative amount to be paid. Exhibit 4 is the most interesting, as this corresponds to our conservative forecast. In column four of this exhibit, we find all the entries are greater than the actual amount paid except three. Since the probability should be no more than 5% that we will underestimate, and since we have 23 observations, the 3 instances in which we underestimated the amount to be paid is a little high, but statistically acceptable. This provides some confirmation that our statistical methodology is working reasonably.

We now seek to see how much better the model's methodology does than a naive approach to estimating disbursements. One simple method of estimating the cumulative value of disbursements to any future date would be to use a regression-generated estimate adjusted for possible differences in disbursements by day of week. This approach should not be confused with the dummy-variable regression approach used by Stone and Miller [8] and Stone and Wood [9]. In point of fact, the regression we use does no more than conditionally average each weekday's disbursements. Given the limited historical data available, it was not possible to identify weekly and monthly patterns in a more sophisticated manner. By using our January and February data, we were able to obtain the following 95% confidence estimate:

$$\text{Cumulative Disbursements} = 175{,}521 \times N_1 + 95{,}151 \times N_2 + 186{,}653 \times N_3 + 171{,}466 \times N_4 + 111{,}366 \times N_5 + 1.6905 \times 100{,}589 \times \sqrt{N_1+N_2+N_3+N_4+N_5}$$

where:

N_1 = number of Mondays in the disbursement forecast period,
N_2 = number of Tuesdays in the disbursement forecast period, etc.

Note that the standard deviation of the forecast is $100,589 which follows a t-distribution with 35 degrees of freedom. This formula is based on the assumption that each day's disbursement is independent of all previous and future disbursements. In the absence of a seasonal or other intra-monthly pattern not corrected for by the day-of-week regression, this assumption seems reasonable. As a point of information, our weekday correction regression only had an $R^2 = .13$, but the t-statistics for all days of the week were significant at the 99% confidence level. Thus, the regression shows a small but predictable weekday bias.

Exhibit 5 provides a direct comparison between the regression forecast method and the method used by the model. Notice that the model shows projected cash flows that are in almost every case lower than the regression forecast. Moreover, as the forecast period is lengthened, the differences between the two forecasted amounts tend to increase. We conclude that the model provides a better projection simply because it takes advantage of the knowledge of when checks are being mailed in making its projection. Of course, our conclusions here must be tempered by the observation that we performed our analysis on only one company with a relatively small amount of data.

For short-range projections, the model can also take advantage of knowledge of when outstanding checks were paid. Our one-day projections illustrate this. We look at two different cases. First, we assume that all checks that were paid through the previous business day are deleted from the outstanding check file. In the second case, we again make one-day projections, but this time we update the outstanding check file only to a time two days prior to the forecast. For the previous day, we provide the system with information as to the total amount of checks that were paid, but not the actual checks paid. (This second test is useful for evaluating the model in conjunction with balance reporting systems that have the capability of providing the actual checks paid only after a one-day delay.)

Exhibits 6 and 7 present the results that compare

Exhibit 2. Characteristics for March 1977 Disbursements

Date	Checks Outstanding	Checks Written	Checks Paid	Ratio Paid/ Outstanding (%)

the regression approach using the formula given above with one-day projections from our forecasting model under the two different conditions. Notice that the model forecasts are lower on average than the regression forecasts. A very interesting statistic in this regard is the average forecast amount (95% confidence) divided by the actual average daily disbursement amount. This computation yields:

$$\text{Regression Estimate} = \frac{\$319,563}{\$131,578} = 2.42 \text{ days}$$

$$\text{Model Forecast (same day information)} = \frac{\$220,207}{\$131,578} = 1.67 \text{ days}$$

$$\text{Model Forecast (one day delayed information)} = \frac{\$211,506}{\$131,578} = 1.61 \text{ days}$$

This tells us that use of the model can allow a company to reduce precautionary balances by approximately 75% of an average day's disbursement over what would be possible using regression. Again, our results were obtained with only limited data for one company. We are only able to conclude that our forecasting approach appears to be worthy of consideration as a possible forecasting method in similar situations for other companies.

Conclusion

An ability to forecast daily cash disbursements is valuable for several reasons. First, daily cash flow forecasts can help a firm to select the maturity structure for a short-term portfolio of marketable securities. Second, the company can improve repayment timing of short-term borrowings with such information. Third, short-term forecasts provide information for funding disbursement activities when other than a controlled disbursement point is used. Finally, a cash flow forecast is an important element of any company's sophisticated cash control system.

The statistical model described here provides reasonable forecasts of daily cash disbursements. Our

results suggest that managers may significantly reduce idle balances through the use of such forecasting.

As we recognize that disbursements represent only part of the firm's total cash flows, our model is but a first step in the development of a complete cash forecasting system. The next step requires development of a complementary approach for forecasting collection cash flows.

CALL FOR PAPERS

The Eastern Finance Association will hold its annual meeting in Newport, Rhode Island, on April 23, 24, and 25, 1981. For information on the program, write to Professor Ben Branch, Vice President, 1981 EFA Program, School of Business Administration, University of Massachusetts, Amherst, MA 01003.

Investor growth expectations: Analysts vs. history

Analysts' growth forecasts dominate past trends in predicting stock prices.

James H. Vander Weide and Willard T. Carleton

For the purposes of implementing the Discounted Cash Flow (DCF) cost of equity model, the analyst must know which growth estimate is embodied in the firm's stock price. A study by Cragg and Malkiel (1982) suggests that the stock valuation process embodies analysts' forecasts rather than historically based growth figures such as the ten-year historical growth in dividends per share or the five-year growth in book value per share. The Cragg and Malkiel study is based on data for the 1960s, however, a decade that was considerably more stable than the recent past.

As the issue of which growth rate to use in implementing the DCF model is so important to applications of the model, we decided to investigate whether the Cragg and Malkiel conclusions continue to hold in more recent periods. This paper describes the results of our study.

STATISTICAL MODEL

The DCF model suggests that the firm's stock price is equal to the present value of the stream of dividends that investors expect to receive from owning the firm's shares. Under the assumption that investors expect dividends to grow at a constant rate, g, in perpetuity, the stock price is given by the following simple expression:

$$P_S = \frac{D(1+g)}{k-g} \quad (1)$$

where:

P_S = current price per share of the firm's stock;

D = current annual dividend per share;

g = expected constant dividend growth rate; and

k = required return on the firm's stock.

Dividing both sides of Equation (1) by the firm's current earnings, E, we obtain:

$$\frac{P_S}{E} = \frac{D}{E} \cdot \frac{(1+g)}{k-g} \quad (2)$$

Thus, the firm's price/earnings (P/E) ratio is a non-linear function of the firm's dividend payout ratio (D/E), the expected growth in dividends (g), and the required rate of return.

To investigate what growth expectation is embodied in the firm's current stock price, it is more convenient to work with a linear approximation to Equation (2). Thus, we will assume that:

$$P/E = a_0(D/E) + a_1 g + a_2 k. \quad (3)$$

(Cragg and Malkiel found this assumption to be reasonable throughout their investigation.)

Furthermore, we will assume that the required

rate of return, k, in Equation (3) depends on the values of the risk variables B, Cov, Rsq, and Sa, where B is the firm's Value Line beta; Cov is the firm's pretax interest coverage ratio; Rsq is a measure of the stability of the firm's five-year historical EPS; and Sa is the standard deviation of the consensus analysts' five-year EPS growth forecast for the firm. Finally, as the linear form of the P/E equation is only an approximation to the true P/E equation, and B, Cov, Rsq, and Sa are only proxies for k, we will add an error term, e, that represents the degree of approximation to the true relationship.

With these assumptions, the final form of our P/E equation is as follows:

$$P/E = a_0(D/E) + a_1 g + a_2 B + a_3 Cov + a_4 Rsq + a_5 Sa + e. \quad (4)$$

The purpose of our study is to use more recent data to determine which of the popular approaches for estimating future growth in the Discounted Cash Flow model is embodied in the market price of the firm's shares.

We estimated Equation (4) to determine which estimate of future growth, g, when combined with the payout ratio, D/E, and risk variables B, Cov, Rsq, and Sa, provides the best predictor of the firm's P/E ratio. To paraphrase Cragg and Malkiel, we would expect that growth estimates found in the best-fitting equation more closely approximate the expectation used by investors than those found in poorer-fitting equations.

DESCRIPTION OF DATA

Our data sets include both historically based measures of future growth and the consensus analysts' forecasts of five-year earnings growth supplied by the Institutional Brokers Estimate System of Lynch, Jones & Ryan (IBES). The data also include the firm's dividend payout ratio and various measures of the firm's risk. We include the latter items in the regression, along with earnings growth, to account for other variables that may affect the firm's stock price.

The data include:

Earnings Per Share. Because our goal is to determine which earnings variable is embodied in the firm's market price, we need to define this variable with care. Financial analysts who study a firm's financial results in detail generally prefer to "normalize" the firm's reported earnings for the effect of extraordinary items, such as write-offs of discontinued operations, or mergers and acquisitions. They also attempt, to the extent possible, to state earnings for different firms using a common set of accounting conventions.

We have defined "earnings" as the consensus analyst estimate (as reported by IBES) of the firm's earnings for the forthcoming year.[1] This definition approximates the normalized earnings that investors most likely have in mind when they make stock purchase and sell decisions. It implicitly incorporates the analysts' adjustments for differences in accounting treatment among firms and the effects of the business cycle on each firm's results of operations. Although we thought at first that this earnings estimate might be highly correlated with the analysts' five-year earnings growth forecasts, that was not the case. Thus, we avoided a potential spurious correlation problem.

Price/Earnings Ratio. Corresponding to our definition of "earnings," the price/earnings ratio (P/E) is calculated as the closing stock price for the year divided by the consensus analyst earnings forecast for the forthcoming fiscal year.

Dividends. Dividends per share represent the common dividends declared per share during the calendar year, after adjustment for all stock splits and stock dividends). The firm's dividend payout ratio is then defined as common dividends per share divided by the consensus analyst estimate of the earnings per share for the forthcoming calendar year (D/E). Although this definition has the deficiency that it is obviously biased downward — it divides this year's dividend by next year's earnings — it has the advantage that it implicitly uses a "normalized" figure for earnings. We believe that this advantage outweighs the deficiency, especially when one considers the flaws of the apparent alternatives. Furthermore, we have verified that the results are insensitive to reasonable alternative definitions (see footnote 1).

Growth. In comparing historically based and consensus analysts' forecasts, we calculated forty-one different historical growth measures. These included the following: 1) the past growth rate in EPS as determined by a log-linear least squares regression for the latest year,[2] two years, three years, . . ., and ten years; 2) the past growth rate in DPS for the latest year, two years, three years, . . ., and ten years; 3) the past growth rate in book value per share (computed as the ratio of common equity to the outstanding common equity shares) for the latest year, two years, three years, . . ., and ten years; 4) the past growth rate in cash flow per share (computed as the ratio of pretax income, depreciation, and deferred taxes to the outstanding common equity shares) for the latest year, two years, three years, . . ., and ten years; and 5) plowback growth (computed as the firm's retention ratio for the current year times the firm's latest annual return on common equity).

We also used the five-year forecast of earnings

Reproduced with permission of the copyright owner. Further reproduction prohibited without permission.

per share growth compiled by IBES and reported in mid-January of each year. This number represents the consensus (i.e., mean) forecast produced by analysts from the research departments of leading Wall Street and regional brokerage firms over the preceding three months. IBES selects the contributing brokers "because of the superior quality of their research, professional reputation, and client demand" (IBES *Monthly Summary Book*).

Risk Variables. Although many risk factors could potentially affect the firm's stock price, most of these factors are highly correlated with one another. As shown above in Equation (4), we decided to restrict our attention to four risk measures that have intuitive appeal and are followed by many financial analysts: 1) B, the firm's beta as published by Value Line; 2) Cov, the firm's pretax interest coverage ratio (obtained from Standard & Poor's Compustat); 3) Rsq, the stability of the firm's five-year historical EPS (measured by the R^2 from a log-linear least squares regression); and 4) Sa, the standard deviation of the consensus analysts' five-year EPS growth forecast (mean forecast) as computed by IBES.

After careful analysis of the data used in our study, we felt that we could obtain more meaningful results by imposing six restrictions on the companies included in our study:

1. Because of the need to calculate ten-year historical growth rates, and because we studied three different time periods, 1981, 1982, and 1983, our study requires data for the thirteen-year period 1971-1983. We included only companies with at least a thirteen-year operating history in our study.
2. As our historical growth rate calculations were based on log-linear regressions, and the logarithm of a negative number is not defined, we excluded all companies that experienced negative EPS during any of the years 1971-1983.
3. For similar reasons, we also eliminated companies that did not pay a dividend during any one of the years 1971-1983.
4. To insure comparability of time periods covered by each consensus earnings figure in the P/E ratios, we eliminated all companies that did not have a December 31 fiscal year-end.
5. To eliminate distortions caused by highly unusual events that distort current earnings but not expected future earnings, and thus the firm's price/earnings ratio, we eliminated any firm with a price/earnings ratio greater than 50.
6. As the evaluation of analysts' forecasts is a major part of this study, we eliminated all firms that IBES did not follow.

Our final sample consisted of approximately sixty-five utility firms.[3]

RESULTS

To keep the number of calculations in our study to a reasonable level, we performed the study in two stages. In Stage 1, all forty-one historically oriented approaches for estimating future growth were correlated with each firm's P/E ratio. In Stage 2, the historical growth rate with the highest correlation to the P/E ratio was compared to the consensus analyst growth rate in the multiple regression model described by Equation (4) above. We performed our regressions for each of three recent time periods, because we felt the results of our study might vary over time.

First-Stage Correlation Study

Table 1 gives the results of our first-stage correlation study for each group of companies in each of the years 1981, 1982, and 1983. The values in this table measure the correlation between the historically oriented growth rates for the various time periods and the firm's end-of-year P/E ratio.

The four variables for which historical growth rates were calculated are shown in the left-hand column: EPS indicates historical earnings per share growth, DPS indicates historical dividend per share growth, BVPS indicates historical book value per share growth, and CFPS indicates historical cash flow per share growth. The term "plowback" refers to the product of the firm's retention ratio in the currennt year and its return on book equity for that year. In all, we calculated forty-one historically oriented growth rates for each group of firms in each study period.

The goal of the first-stage correlation analysis was to determine which historically oriented growth rate is most highly correlated with each group's year-end P/E ratio. Eight-year growth in CFPS has the highest correlation with P/E in 1981 and 1982, and ten-year growth in CFPS has the highest correlation with year-end P/E in 1983. In all cases, the plowback estimate of future growth performed poorly, indicating that — contrary to generally held views — plowback is not a factor in investor expectations of future growth.

Second-Stage Regression Study

In the second stage of our regression study, we ran the regression in Equation (4) using two different measures of future growth, g: 1) the best historically oriented growth rate (g_h) from the first-stage correlation study, and 2) the consensus analysts' forecast (g_a) of five-year EPS growth. The regression results, which are shown in Table 2, support at least

two general conclusions regarding the pricing of equity securities.

First, we found overwhelming evidence that the consensus analysts' forecast of future growth is superior to historically oriented growth measures in predicting the firm's stock price. In every case, the R^2 in the regression containing the consensus analysts' forecast is higher than the R^2 in the regression containing the historical growth measure. The regression coefficients in the equation containing the consensus analysts' forecast also are considerably more significant than they are in the alternative regression. These results are consistent with those found by Cragg and Malkiel for data covering the period 1961-1968. Our results also are consistent with the hypothesis that investors use analysts' forecasts, rather than historically oriented growth calculations, in making stock buy–and–sell decisions.

TAW_R_COCDR1#80Attachment
Page 730 of 739

Second, there is some evidence that investors tend to view risk in traditional terms. The interest coverage variable is statistically significant in all but one of our samples, and the stability of the operating income variable is statistically significant in six of the twelve samples we studied. On the other hand, the beta is never statistically significant, and the standard deviation of the analysts' five-year growth forecasts is statistically significant in only two of our twelve samples. This evidence is far from conclusive, however, because, as we demonstrate later, a significant degree of cross-correlation among our four risk variables makes any general inference about risk extremely hazardous.

Possible Misspecification of Risk

The stock valuation theory says nothing about which risk variables are most important to investors. Therefore, we need to consider the possibility that the risk variables of our study are only proxies for the "true" risk variables used by investors. The inclusion of proxy variables may increase the variance of the parameters of most concern, which in this case are the coefficients of the growth variables.[4]

To allow for the possibility that the use of risk proxies has caused us to draw incorrect conclusions concerning the relative importance of analysts' growth forecasts and historical growth extrapolations, we have also estimated Equation (4) with the risk variables excluded. The results of these regressions are shown in Table 3.

Again, there is overwhelming evidence that the consensus analysts' growth forecast is superior to the historically oriented growth measures in predicting the firm's stock price. The R^2 and t-statistics are higher in every case.

	(6.93)	(6.93)	(15.93)	(11.02)	

Notes:
* Coefficient is significant at the 5% level (using a one-tailed test) and has the correct sign. T-statistic in parentheses.

CONCLUSION

The relationship between growth expectations and share prices is important in several major areas of finance. The data base of analysts' growth forecasts collected by Lynch, Jones & Ryan provides a unique opportunity to test the hypothesis that investors rely more heavily on analysts' growth forecasts than on historical growth extrapolations in making security buy–and–sell decisions. With the help of this data base, our studies affirm the superiority of analysts' forecasts over simple historical growth extrapolations in the stock price formation process. Indirectly, this finding lends support to the use of valuation models whose input includes expected growth rates.

[1] We also tried several other definitions of "earnings," including the firm's most recent primary earnings per share prior to any extraordinary items or discontinued operations. As our results were insensitive to reasonable alternative definitions of "earnings" we report only the results for the IBES consensus.

[2] For the latest year, we actually employed a point-to-point growth calculation because there were only two available observations.

[3] We use the word "approximately," because the set of available firms varied each year. In any case, the number varied only from zero to three firms on either side of the figures cited here.

Fixing dams won't solve water problem

By Linda Bridwell

Kentucky legislators' recent decision to allocate funds for the replacement of Kentucky River dams is great news for Central Kentucky.

Kentucky American Water has advocated for repairs to the dams for years. As a company, we first identified the need for a long-term water supply solution in 1986. Our company is very pleased to see this support for the Kentucky River Authority and one of the most important projects of this century.

Certainly, repairing the aging dams is a critical component to addressing the water supply problem our region faces. After all, the Kentucky River remains the primary water source for Kentucky American Water's more than 114,000 customers and for those of numerous other water utilities in the area. But the solution to our region's water-supply deficit cannot stop there.

To sufficiently address the water needs for our region, additional measures are required. We caution those who believe that restoring the dams and raising Dam 10 solves the water supply problem.

The Bluegrass Water Supply Commission is a group of water suppliers from throughout the region who have collectively studied the water supply issue since 1999. This group agreed in 2005on a regional solution that included additional water supply behind a raised Dam 10.

It concluded that even with this additional supply, there would not be enough water to meet all of the region's water needs during a drought, and that there would not be enough water to erase Kentucky American Water's current water supply deficit.

Add to this the fact that it is not clear how the additional water that would be available would be allocated among users.

The consensus for a regional solution is a treatment plant downstream on the Kentucky River. Kentucky American was ordered by the Kentucky Public Service Commission in 1997 to solve the water supply issue for our customers and has become concerned about the funding and time line for implementing the regional solution.

Therefore, Kentucky American recently began the process of moving forward with the design of a treatment plant on Kentucky River pool 2 or 3 that can solve the water supply deficit.

As a participant in, but not a voting member of, the Bluegrass Water Supply Commission, we continue dialogue with the commission to determine how it and our company might work together to make this effort part of the regional solution and make the regional solution a reality.

We agree that solutions to Central Kentucky's water supply situation will not be simple or inexpensive, but solving this problem with no more delays has become critical.

For the first time in my memory, there is real momentum to solve the most important water issue our region faces. With funding for the dams in sight, design for a downstream treatment plant moving forward and continued discussion between Kentucky American and the Bluegrass Water Supply Commission, we are optimistic that this longstanding issue is closer than it ever has been to being solved.

Linda Bridwell is the project delivery and developer services manager for Kentucky American Water.

FOR IMMEDIATE RELEASE

KENTUCKY AMERICAN WATER RESPONDS TO JULY 10 LFUCG WORK SESSION
Statement from Linda Bridwell, Manager of Engineering and project manager

Lexington, Ky., (July 5, 2007) – "Kentucky American Water remains focused on moving forward with the Kentucky River project the company filed with the Public Service Commission earlier this year. We respect Louisville Water Company and appreciate their cooperation over the years in working on a water supply solution for Central Kentucky. However, we and the Bluegrass Water Supply Commission chose not to pursue a project with LWC because a number of factors changed since this was last considered in 1999 – including the scope of the project and the cost. The current regional project can be implemented sooner, and we can't afford any more delays.

Based on extensive research conducted by two well-respected engineering firms, Kentucky American Water, the BWSC, and the Bluegrass Area Development District agree that the project submitted is the most cost-effective and feasible approach to solving our region's water supply problem. That said, additional debate regarding options will be covered in the PSC's extensive review process."

Kentucky American Water®

Opinion-Editorial
August 6, 2007

To the Editor of the Georgetown News-Graphic:

The Kentucky River solution to the regional water deficit, which Kentucky American Water submitted to the Public Service Commission (PSC), is the least expensive and most feasible option for solving Central Kentucky's water supply problems.

Many regional water utility experts have researched countless alternatives, working with two nationally recognized, independent engineering firms. Our project, which includes a new treatment plant on Pool 3 of the Kentucky River, was selected as the best by both Kentucky American Water and the Bluegrass Water Supply Commission (BWSC), of which the city of Georgetown is a member.

At first glance some general figures provided recently by Louisville Water Company at a Lexington council meeting for a water line between that city and Lexington may appear less expensive. However, in the mid-and long-term, it is significantly more costly and potentially implausible.

In fact, multiple Louisville Water Company proposals were considered during the extensive review process that ultimately led our company and the BWSC to our Kentucky River solution. In addition to cost, permitting issues, such as running parallel to I-64, and the need for a much longer water line made the Louisville option less feasible than the detailed plan that is now well along in the PSC review process.

This project involves less than 11 miles in Scott County and we are committed to doing the utmost to protect the environment, historic elements and private property. Easement agreements with property owners primarily provide us access to property during construction. Most residents soon forget underground lines exist along their property since they can soon resume all normal activities. Grass, trees, landscaping, fencing and other enhancements are replaced as part of the agreement.

The PSC will scrutinize the application and approve or deny it based on the feasibility and cost. At $160 - $170 million, the estimated investment is significant, but a value when human health and economic viability are considered.

This project is desperately needed throughout Central Kentucky, including Georgetown/Scott County. Kentucky American Water and representatives of the BWSC are pleased to talk with individuals or groups to share more information. More information is also available at bluegrasswater.com

Utility has best water-supply plan

By Linda Bridwell

The Kentucky River solution to the regional water deficit, which Kentucky American Water submitted to the state Public Service Commission, is the least expensive and most feasible option for solving Central Kentucky's water-supply problems.

Many regional water utility experts have researched countless alternatives, working with two nationally recognized, independent engineering firms.

Our project, which includes a new treatment plant on Pool 3 of the Kentucky River, was selected as the best by both Kentucky American Water and the Bluegrass Water Supply Commission, of which the city of Lexington is a member.

Linda Bridwell is manager of engineering at Kentucky American Water and the water-supply project manager.

At first glance, some general figures provided recently by Louisville Water Co. at a Lexington council meeting for a water line between the two cities may appear less expensive. However, in the mid- and long-term, the Louisville plan is significantly more costly and potentially implausible.

In fact, multiple Louisville Water Co. proposals were considered during the extensive review process that ultimately led Kentucky American and the water-supply commission to the Kentucky River solution.

In addition to cost, permitting issues, such as running parallel to Interstate 64, and the need for a much longer water line made the Louisville option less feasible than the detailed plan that is now well along in the PSC review process.

We are committed to doing the utmost to protect the environment, historic elements and private property. Most residents soon forget that underground lines exist along their property since they can soon resume all normal activities. Grass, trees, landscaping, fencing and other enhancements are replaced.

The PSC will scrutinize the application and approve or deny it based on the project's feasibility and cost. At $160 million to $170 million, this project is a value when human health, economic viability and the impact on customer rates are considered.

This solution is desperately needed throughout Central Kentucky.

Letter to the Editor of *The Winchester Sun*

(Also submitted via email to rpatrick@winchestersun.com)

Mike Wynn's Dec. 4 article on water supply included a statement that the regional water supply solution fell "through because Kentucky American Water withdrew from the talks." In fact, Kentucky American Water was an active participant, along with the Winchester Municipal Utilities, in the Bluegrass Water Supply Consortium. This group studied the regional water supply issue between 1999 and 2004, and in 2005 officially became the Bluegrass Water Supply Commission (BWSC).

The BWSC's proposed plan included a regional water treatment plant at Pool 3 of the Kentucky River near Frankfort, a transmission main into Central Kentucky and a grid system for water distribution to area water utilities. Kentucky American Water would purchase over two-thirds of the water produced by the plant. When this group formally became a regional water commission, Kentucky American Water continued to work with the group as a partner, although as private water utility it was legally excluded from membership.

In 2006, the company determined that in order to meet the needs of its customers, it should move forward more quickly on this project than the BWSC proposed. The company announced that it would design a water treatment plant on Pool 3 (as the BWSC plan recommended) within one year and continue to partner with the BWSC on the possibility of the plant being a regional operation.

The project is now 70 percent complete. Kentucky American Water remains willing and able to work with any regional utility, including Winchester, on partnerships for their water supply. This new system offers great opportunities for Central Kentucky at a substantially lower cost than other solutions currently under consideration.

KENTUCKY
AMERICAN WATER

Stick with the Facts

Kentucky American Water initiated an historic project in June 2008, beginning construction of a new 20 million gallon per day (MGD) water treatment plant at Pool 3 of the Kentucky River, a 3 million gallon storage tank and booster pumping station, and 30.5 miles of 42-inch transmission main. This critical project is the solution to Central Kentucky's water deficit after nearly twenty years of review of various alternatives.

The Kentucky Public Service Commission comprehensively reviewed the proposed facilities for over a year, and found they were economically feasible and necessary to provide adequate service. The PSC fully investigated Kentucky American Water's review of potential solutions and granted approval to construct the facilities. Other potential alternatives were either inadequate or more expensive than the approved project. The proceedings required rigorous analysis of costs and provided opportunities for public review and participation.

The project is actually three simultaneous construction projects. Construction is currently on budget, and on schedule for completion in the Summer of 2010. As the recent 2007 drought demonstrated, this project is critical to meeting central Kentucky's existing water needs. This project also provides supplies to meet future water needs through 2030. The current economic situation and its slight impact on immediate water use do not eliminate the current or future need for the project. In early April, the treatment facility was nearly one-third complete and almost half of the pipeline was installed. The Company has acquired 91% of the property easements required for completion of the pipeline construction.

Despite challenging conditions associated with winter-time construction, Kentucky American Water and its contractors are committed to regulatory compliance. The contractors have been limited in doing final grading and road paving work because of the wet, wintry conditions but have initiated those efforts as the weather now permits. Where the road has been impacted, new pavement will be applied once most heavy equipment use of the roads is completed. Soil erosion control measures have been established, maintained, and adjusted as necessary. Kentucky American Water and the contractor have made adjustments to maintain compliance with transportation and environmental permits, minimizing the impact to area residents. Sensitive to local residents' concerns, the Transportation Cabinet located an inspector at the project site to check progress and monitor permit compliance.

The project will do more than just provide Central Kentucky with a safe and reliable water supply for years to come. It will also contribute more than $1.1 million in additional property taxes annually in Fayette, Franklin, Scott and Owen Counties. Kentucky American Water worked with the Franklin County Fire Department to place flushing fire hydrants in strategic locations along the pipeline route to maximize fire protection capabilities.

Kentucky American Water worked since 1999 with the Bluegrass Water Supply Commission to develop a regional project that utilized the Kentucky River and met the needs of all of Central Kentucky. Although currently no other regional utilities have committed to participate in the project, Kentucky American Water will continue its commitment to a regional partnership in the facilities for the future. The facilities can be expanded in 5 MGD increments up to 30 MGD.

The project is estimated to cost $162 million. That will ultimately be an increase on the average residential water bill between $8 and $10 monthly. On a daily basis, this translates into 33 cents per day for a new 20-million gallon per day water treatment plant. Kentucky American Water is pursuing all opportunities to reasonably minimize the cost of the project, including lower cost financing for a portion of the project.

Kentucky American Water employees are proud to be a part of this community and have the opportunity to meet our current and future water needs with the new project. We're proud to be your water company and take our accountability, resource stewardship and community responsibilities very seriously.

TENNESSEE AMERICAN WATER COMPANY
DOCKET NO. 12-00049
FIRST DISCOVERY REQUEST OF THE
CITY OF CHATTANOOGA

Responsible Witness: Linda C. Bridwell

Other Participating Employees: None

Question:

81. Please ***Identify*** and produce any and all ***Documents*** or evidence of any kind that ***TAWC*** intends to offer as evidence at the hearing or to refer to in any way at the hearing.

Response:

TAW intends to offer the testimony and exhibits which it has already filed in this docket along with the responses it has provided to data and discovery requests from the TRA staff and intervenors. Based on previous cases, TAW would fully expect to offer additional testimony, rebuttal testimony and any document produced in further discovery in this proceeding. Having said all of that, TAW has not made final decisions as to what documents and/or evidence it will introduce at the evidentiary hearing and specifically reserves the right to do so at a later date closer to the time of hearing.

TENNESSEE AMERICAN WATER COMPANY
DOCKET NO. 12-00049
FIRST DISCOVERY REQUEST OF THE
CITY OF CHATTANOOGA

Responsible Witness: **Linda C. Bridwell**

Other Participating Employees: **None**

Question:

82. If your response to any of the City of Chattanooga's Requests for Admission was anything other than an unqualified admission, please ***Explain*** the basis for your failure to admit each such request without qualification and ***Identify*** all ***Documents*** related to, referring to, or describing the basis for that failure.

Response:

Please refer to the response to each Request for Admission.

TENNESSEE AMERICAN WATER COMPANY
DOCKET NO. 12-00049
FIRST DISCOVERY REQUEST OF THE
CITY OF CHATTANOOGA

Responsible Witness: Gary M. VerDouw

Requests for Admission:

1. Please admit that the document attached as. Exhibit 1 to this Request is a genuine copy of AWWC's Form 10-K filed with the United States Securities and Exchange Commission for the fiscal year ended December 31, 2011.

Response:

Exhibit 1 is the genuine copy of AWWC's Form 10-K filed with the SEC for December 31, 2011. There are ten supplemental pages not attached to Exhibit 1. These pages include certifications, consent, and an American Water Works Company, Inc. subsidiary list. Please see the attachment for these ten pages.

Exhibit 31.1

CERTIFICATION OF PRINCIPAL EXECUTIVE OFFICER

I, Jeffry Sterba, certify that:

1. I have reviewed this annual report on Form 10-K of American Water Works Company, Inc.;

2. Based on my knowledge, this report does not contain any untrue statement of a material fact or omit to state a material fact necessary to make the statements made, in light of the circumstances under which such statements were made, not misleading with respect to the period covered by this report;

3. Based on my knowledge, the consolidated financial statements, and other financial information included in this report, fairly present in all material respects the financial condition, results of operations and cash flows of the registrant as of, and for, the periods presented in this report;

4. The registrant's other certifying officer and I are responsible for establishing and maintaining disclosure controls and procedures (as defined in Exchange Act Rules 13a-15(e) and 15d-15(e)) and internal control over financial reporting (as defined in Exchange Act Rules 13a-15(f) and 15d-15(f)) for the registrant and have:

a) Designed such disclosure controls and procedures, or caused such disclosure controls and procedures to be designed under our supervision, to ensure that material information relating to the registrant, including its consolidated subsidiaries, is made known to us by others within those entities, particularly during the period in which this report is being prepared;

b) Designed such internal control over financial reporting, or caused such internal control over financial reporting to be designed under our supervision, to provide reasonable assurance regarding the reliability of financial reporting and the preparation of financial statements for external purposes in accordance with generally accepted accounting principles;

c) Evaluated the effectiveness of the registrant's disclosure controls and procedures and presented in this report our conclusions about the effectiveness of the disclosure controls and procedures, as of the end of the period covered by this report based on such evaluation; and

d) Disclosed in this report any change in the registrant's internal control over financial reporting that occurred during the registrant's most recent fiscal quarter (the registrant's fourth fiscal quarter in the case of an annual report) that has materially affected, or is reasonably likely to materially affect, the registrant's internal control over financial reporting; and

5. The registrant's other certifying officer and I have disclosed, based on our most recent evaluation of internal control over financial reporting, to the registrant's auditors and the audit committee of the registrant's board of directors (or persons performing the equivalent functions):

a) all significant deficiencies and material weaknesses in the design or operation of internal control over financial reporting which are reasonably likely to adversely affect the registrant's ability to record, process, summarize and report financial information; and

b) any fraud, whether or not material, that involves management or other employees who have a significant role in the registrant's internal control over financial reporting.
